![Diagram](image)

**FIG. 3.—HALF-DIAGRAMMATIC FIGURE OF THE CEREBRAL CORTEX, magnified about 250 diameters, giving a view of the entire arrangement of the different zones of cells, and their relations to one another, and to the surrounding neuroglia. (Lays.) The region A corresponds to the sub-enchephalic network of the neuroglia. The region B to the sub-encepalial zones of small cells (region of the periorans communes); the region C is intermediate between the sub-encepalial and the deeper zones of cells which are indicated at D. As E we note the dipping of the fasciculi of white substance into the plexus of cortical cells. F represents a capillary at the moment when it plunges into the tissues of the cortex.**

This stratum of the cortex has been compared by Layes to the epithelial covering of the mucous and cutaneous surfaces of the body, since he believes that it is designed to protect the nerve-cells from direct contact with the capillaries of the pia mater.

While serving thus as a source of protection and isolation, it probably also filters, as it were, the juices which escape from the meningeal vessels for the nourishment of the nervous elements. This view seems to be supported by a peculiarity in the arrangement of the smaller vessels, which can be traced into the substance of the cortex. They are found to be surrounded for almost their entire circumference by an adventitious sheath, which "invests them like a muff," and prevents the nerve-cells from coming into direct contact with any portion of the vascular system. We are forced, therefore, to believe that the nerve-cells derive their nutritive elements only through the mediation of other structures. The external layer of the cortex will subsequently be considered in greater detail.

*(To be continued.)*

---

**A CASE OF MASCULINE FALSE HERMAPHRODITISM IN A CALF.**

The subject of this observation was a calf, a year old, light red in color, belonging to Dr. Stephen C. Martin, the cultivator of animal vaccine, who very kindly placed it at my disposal for examination.

**External Appearances.—** The head was more male than female in appearance. The horns were three inches long, and haired to within one inch of the tips. The animal betrayed the sexual irritability and action of the male, and was beginning to be ugly in disposition. The vulva was wanting, and there was no intimation of any introitus vaginae. The skin in the immediate locality of what should be the region of the external sexual organs of a female was very smooth and hairless; from it extended a peculiar body, resembling a flexed little finger as much as anything, which was an enlarged clitoris. It was impossible to recognize anything of a preputial character; it came out of the skin, and was covered by a smooth skin or membrane; therefore it did not extend out of a prepucean, but, if extended, simply curled on itself upward toward the anus, just as one flexes the smaller digit when closing the hand. The orifice urethra was very small, not easily to be seen, immediately above the clitoris; it admitted a No. 6 catheter (English), which passed in 13 cm. before the urine flowed. The animal passed urine in a very singular manner, i.e., not in a steady stream, but spasmodically so far as the distance which it went from the body was concerned; sometimes it flowed out, then with a spasm it would go in a small stream six or eight feet behind the animal, varying in this way until the operation was completed. When one examined the parts around the clitoris, a peculiar convoluted mass was to be felt, situated subcutaneously and immediately anterior to the clitoris.

No other indications of a penis could be seen or felt on external examination. No scrotum was present. The raphé was indistinctly indicated. Four elongated, roundish bodies were to be both seen and felt in the position of the
testicles, but they did not depress the skin—i. e., were not pendent—when the animal was standing. They are made apparent in the illustration (Fig. 1) by drawing the skin tightly forward over the abdomen. Two sets of testes were visible. No indications of an udder were discernible either micro- or macroscopically. The posterior testes resembled those generally seen in bulls; they were 1 cm. long, and solid; the anterior pair were more widely separated—2 cm. long, and had a canal, out of which could be pressed a slight amount of pearly-colored fluid.

**Internal Examination.**—Very careful removal of the skin revealed the entire absence of any serotal tunic to the testicles. The external appearance of two sets was confirmed. The anterior or true testes were 5 cm. long and 3 cm. thick; the supplementary testes were 4 cm. long and 2.5 cm. thick, and had a ligamentous connection with the anterior ones, in which ran blood-vessels and nerves, but nothing having the appearance of ducts. The epididymis was well developed in the anterior pair, but was wanting in the posterior. In the supplementary testicles two ducts, 10 cm. long, were to be seen, one from each, extending to the penis, or what answered to it, and becoming lost in the convoluted mass previously mentioned. A very thin serous membrane covered these supplementary organs. On cutting them open, they presented a smooth surface, less spongy than the regular tissue of the testicles. The parenchyma had a peculiar ashen-gray color, with white striæ running from the center of the body toward the periphery, and a markedly developed corpus Highmori. It was at first thought that these organs might be ovaries, but an inspection of the cut surface, with subsequent microscopical examination, sufficiently demonstrated their testicular character, with a great predominance of connective tissue. The epididymis was wanting, as was previously mentioned.

As can be seen in the illustration (Fig. 2), the anterior pair of testicles had all the normal attributes, save the embracing tunics; they hung free in a mass of loose connective tissue, from which the cords were easily loosened to the inguinal ring, toward which they may be seen extending. The cremasters were exceedingly well developed. Here comes the question about the gubernaculum Hunteri and the hypothetical part it plays in the descent of the testicle. Of course, the usual remnant adherent to the walls of the scrotum was wanting, and no rudiment of any such organ was to be seen.*

The epididymis was well developed, and the seminal ducts could be easily traced along the spermatic cord until they entered the ring. Cross-section of these organs presented to view a parenchyma having the peculiar dark

---

* Let me here remark that the teleological theorist would often seem to have some grounds for his belief, for we frequently find that natural laws place at our disposal a certain species of animal by which hypothetical questions can alone be decided. It is so with the question of the function of this so-called gubernaculum Hunteri. In almost all the domesticated mammalia, as well as in man, the testicles descend before birth, hence in an embryonal state. In the horse they do not descend until some months after birth, and therefore this animal offers the opportunity to settle the question. I have in vain tried to get male colts prematurely born, or that had died within a few weeks after birth, in order to make such studies; perhaps some inquiring reader may be more fortunately situated. I suggest it as an object for original research, and a subject for a valuable paper. Pigs, cats, or dogs will not answer the purpose, nor yet calves, unless got very young, as embryos, and then not as well as colts.
orange-yellow customarily seen in these organs in the bull. It was spongy, and swelled up beyond the level of the thin albuginea. Microscopical examination gave evidence of its true nature; but the cells were very immature, small, round, and epithelial. No traces of spermatozoa were to be discovered. The length of the funiculus was 24 ctm.

led to the determination that it was a rudimentary uterus. The horns of this organ were three inches long; the body, of or neck, two inches. The horns had a very distinct lumen, which united in the cavity of the body as a cul-de-sac. This uterus-like body was immediately above the bladder, and terminated bluntly, as a sort of tuberosity, above the penis, being intimately connected with it, but having no internal communication with its interior.

The Penis.—The urethra did not run through the penis for its entire length (i. e., its intra-pelvic portion, which was all there was present), but consisted of a thin-walled canal, running along its superior surface and entering it at the pars cavernosa. From the latter, with its peculiarly powerful accelerator urine (in the bull), to the termination of this organ in the clitoris, were to be seen two convoluted masses. The normal penis of the bull possesses a peculiar sigmoid curvature, situated immediately posterior to the scrotum, provided with retractor muscles, which are attached to the ischium (see Fig. 3). This sigmoid curvature was here favored with a dual representation. The one immediately adjoining the clitoris was somewhat normal in its course, i. e., its folds were parallel to the course of the penis; the retractors were, of course, wanting, while in the anterior curvature the coils were one above another, like those of a coil of rope. All this part of the penis was solid. This portion was about 10 ctm. in length.

The only portion of the penis which resembled the nor-
CLEMENTS: DISLOCATION OF THE STERNAL END OF THE CLAVICLE.

BY B. A. CLEMENTS, M. D.,
SURGEON, U. S. ARMY.

The history of this case of rather rare dislocation is transcribed from the original report in the office of the Surgeon-General of the army.

Sergeant S. Martin, General Mounted Service, a spare and active man, aged about thirty-six years, fell head foremost down a dry well at St. Louis Barracks, Missouri, on March 6, 1873. The well was sixteen feet deep, and at ten feet from the top there was a large projecting rock. He struck the latter with the back of his left shoulder.

The shock of the injury was considerable. On examination, the left shoulder and the back of his neck and of his left arm were found much scraped and bruised, but there was no fracture. The following morning it was seen that the sternal end of the clavicle was dislocated backward and somewhat downward.

Pulling the shoulders strongly backward, and at the same time placing the knee between the scapula, partly restored the bone to its proper position, but not entirely so, it being also necessary to pull up the end by the fingers, which procedure was not difficult owing to his lack of flesh. A large pad was put between his shoulders and he was laid on his back; this, however, did not suffice to keep the bone in position, and the ordinary rings and tapes, so useful in fractured clavicle, were applied, and with great success, the end of the bone being kept well in position.

The apparatus was removed on April 10th, five weeks after the receipt of the injury, and the bone found to be firmly joined to its attachments. He complained now solely of stiffness of his left shoulder, and inability to use his arm as well as formerly.

He continued under observation until August, and frictions and iodine were used to his left shoulder joint without much benefit. There was no swelling about the joint, but there was a shrinking of the deltoid—not great, but yet perceptible. He could raise his arm only to an angle of some sixty degrees. No improvement in this condition having occurred in the course of four months, he was discharged the service on August 3, 1873.

He would seem to have recovered in great measure the use of the deltoid, as a few months after his discharge he was employed in driving a street car.

This rare injury was caused, as will be observed, by the shoulder being driven forward and inward. The success of the treatment with the ring apparatus for fractured clavicle was perfect, the dislocated bone being retained in position almost immovably.

Note.—A case of dislocation of the sternal end of the clavicle "upward" is mentioned in Part III of the "Medical and Surgical History of the War of the Rebellion," Surgical Vol. p. 646.

ARMY BUILDING, NEW YORK CITY,
September 5, 1883.

Book Notices.

Dr. G. Beck's therapeutischer Almanach. 10 Jahrgang, 1883.
Das Taschenbuch der neuesten Therapie III. Bändchen, I. Heft. Bern: J. Dulp, 1883. 32mo, pp. 76.

This little book contains, in the briefest possible form, a series of classified references respecting the latest discoveries in therapeutics. Each disease in regard to which any therapeutical novelty is offered is found in its place, arranged according to a systematic classification, and under it the reference is made—usually to the "Index Medicus," Schmidt's "Jahrbücher," the "Jahresbericht" of Virchow and Hirsch, or some other periodical of the same class. For instance, under the head of the "apyreic dysuria," we find diabetes; and here, among other references, we read "Arsen. brom. Lq. 3 mil 1-3 Tr. p. die.—Clemens, M. Z. (89)." Which signifies: Clemens, in the "Medical-zeitung" for 1883, recommends the use of solution of bromide of arsenic in doses gradually increasing from one to three drops three times a day. Sometimes the references are more specific, as in the following: "Chin. sulft. 0'4, 2 mil p. die während 15-20 Tagen, Ind. bei Zuckerzahn ohne funktionelle Veränderungen, wahrscheinlich neurogesehen Eruprungen.—Worms, M. Z. (82), 449." In other cases the references are even more extended. In addition, very brief outlines of the bibliography of the more important subjects are given here and there throughout the book. Finally, there is an index of all the remedies mentioned, also an appendix containing such notices of preparations and their uses as do not naturally fall under the head of disease. The book is, in reality, just such an index rerum as a pretty-well-read man would make for his own use out of his own reading, and, like such an index, it will be valuable or not according as the reader uses it as a guide to his reading or as a substitute for it.

This quarto volume is divided into two parts—namely, the anatomy of joints, and an atlas of diseases of the articulations. The former is very concise, and is illustrated with some excellent wood-cuts from Luschka's well-known work.

The second part consists of twenty-three lithographic plates and descriptions, illustrating diseases of all the joints. The plates are colored, so that the changes in the joint surfaces are apparent at a glance, and those devoted to pathological anatomy are excellent and well worth careful study. The wood-cuts in the first part are also exceedingly well done. We do not remember to have ever seen better work. If publishers would often put as good illustrations into books, it would add much to their value.

Biddle's "Materia Medica" has long been a favorite textbook with medical students on account of its fulness of detail in botanical, chemical, and pharmaceutical matters, which in other works are so frequently slighted. In respect to therapeutics, too, it has had the reputation of being accurate and precise, although very brief. Its chief defect as a text-book, apart from the arbitrary character of its system of classification, has been its neglect of the physiological action of drugs. This defect the author has partially remedied in the present edition, and, although we think that he still errs on the side of brevity, his descriptions of the physiological action in the case of the more important drugs are systematic and accurate. His remarks on new remedies are in the main judicious. We have, however, looked in vain for some reference to quebracho and nitro-glycerin, and, although the author mentions the composition of the oil of wintergreen as a salicylate of methyl, he does not speak of the antirheumatic action which it exerts in common with the other salicylates. Other remedies which have attracted more or less attention of late years, and which he does not describe, are the bronide and iodide of ethyl, quinoline, coto bark, chaulmoogra oil, pyrogallic acid, and the Jamaica dog-wood (Piscidia erythrina). The author, we may note, is rather inconsistent in his use of terms, following the new pharmacopoeia in general in the use of the termination ina for alkaloids, but still designating the alkaloid of cinchona as quina.

In spite of these strictures, the book must still be regarded as very fairly brought up to the times, and calculated to serve as a reliable guide; and, as a manual for students, it is, in our opinion, an excellent one.

This book is a treatise for the physiological laboratory, containing a clear and systematic description of the way in which experiments are to be conducted for determining the effects of drugs upon the animal organism. It describes in detail the methods and instruments employed in the investigation of the action of drugs upon tissues isolated from the organism, the methods of introduction of drugs into the system, the ways in which the transformation of drugs in the system and their elimination are observed, and the processes by which we estimate their action upon the functions of circulation, respiration, digestion, secretion, excretion, and reproduction, and upon the body—temperature and muscular and nervous energy. Such a work being entirely technical in character, there is little to say in criticism, especially when it is issued by a man so presumably competent as the professor of physiology in Zurich. It need only be said that Dr. Smith's additions, which occupy a good part of the volume, are judicious and useful, and that for the experimenter in animal physiology the book will possess considerable value.

The Scientific Transactions of the Royal Dublin Society. Vol. I (Series II), Parts xv, xvi, xvii, xviii, xix; Vol. II (Series II), Dublin, 1880−82.

Of these two publications of the Royal Dublin Society, the "Transactions" and the "Proceedings," the former are contained in volumes of rather appalling size, comprising a dissertation upon the Dyseystide, or carnivorous beetles (this paper alone covering a thousand pages and delineating fifteen hundred species), and smaller monographs describing certain comets discovered in 1881, the physical appearances of Jupiter, the Laurentian rocks of Donegal, the condition of the British Islands at different geological epochs (a very interesting contribution), and, finally, a series of photographs of spark-spectra of different elementary substances. The "Proceedings" appear in magazine form, and comprise papers upon the Varieties of Birds found in Navarro County, Texas, a Note on the Electro-Magnetic Action of a Moving Electrified Sphere, a New Form of Apparatus for estimating Ammonia in Potable Waters, a New Analysis of the Locan Sulphur Spa, the Mode of Occurrence and Winning of Gold in Ireland, a List of the Parasitical Algæ of the Firth of Forth, and a Catalogue of the Examples of Meteoric Falls in the Museums of Dublin. The titles of these papers sufficiently indicate their character. To the purely medical man they will possess little interest; to those interested in the subjects of which they treat they will doubtless prove of great value.

Experimental Researches on the Tension of the Vocal Bands. (a)—The Action of the Thyro-crioid Muscle. (b)—The Action of the Expiratory Blast of Air. By F. H. Hooper, M. D., Boston. Assistant Physician to the Clinic for Diseases of the Throat, Massachusetts General Hospital, etc. Pp. 20.

Dr. Hooper's pamphlet describes experiments undertaken at the physiological laboratory of the Harvard Medical School to determine the character of the agencies which produce tension of the vocal cords. One of these is the contraction of the crico-thyroid muscle. The mode of action of the latter has been disputed, no fewer than six different functions having been assigned to it. All these have been made on purely theoretical grounds, except in the case of four separate observers, all of whom experimentally determined that its action was to lift the anterior portion of the cricoid cartilage, the thyroid cartilage remaining stationary, while the posterior part of the cricoid cartilage, with its appendages, was depressed. This determination the author confirms by what appear to be perfectly conclusive experiments. He would, therefore, designate the muscle as the thyro-crioid. The second factor in the production of tension of the vocal cords is the blast of air forced out in expiration with a closed glottis. This action, while lifting the whole larynx, raises the cricoid cartilage more than the thyroid; this being accomplished, according to the author, by an increase in the capacity of the laryngeal chamber produced by the sudden entrance of the current of air.

This is simply a list of the preparations of the German pharmacopoeia, with statements of their strength, solubility, and maximum doses. The arrangement is alphabetical, but the preparations are grouped under the head of the drug, and not as separate items.
BOOKS AND PAMPHLETS RECEIVED.

Elements of Histology. By E. Klein, M. D., F. R. S., Joint Lecturer on General Anatomy and Physiology in the Medical School of St Bartholomew’s Hospital, London. Illustrated with one hundred and eighty-one Engravings. Philadelphia: Henry C. Lea’s Son & Co., 1883. 12mo, pp. xii—392. [Students’ Series of Manuals.]

Outline Diagrams of the Ear, for the Pictorial Diagnosis of Diseases of this Organ and its Connections. For the Use of Practitioners, Students, and Clinical Assistants. Cincinnati: A. E. Wilde & Co.

Medical Bibliography. By John S. Billings, M. D., Surgeon, U. S. A., etc. [Reprint from the “Transactions of the Medical and Chirurgical Faculty of Maryland.”]

The Fallacies of Popular Clinical Medicine. By Jarvis S. Wright, M. D., Professor of Surgery. An Introductory Lecture delivered at the Long Island College Hospital.

Observations on the Management of Enteric Fever according to a Plan Based upon the so-called Specific Treatment. Read before the College of Physicians of Philadelphia. By James C. Wilson, M. D., Physician to the Jefferson Medical College Hospital, etc. [Reprint from the “Transactions.”]

Ambulance Service in Philadelphia. By De Forest Willard, M. D., Surgeon to the Presbyterian Hospital, etc.

Correspondence.

LETTER FROM MOBILE.

The Medical College of Alabama.—The late Dr. J. C. Nott.—Succeeding Members of the Faculty.—The City Hospital.—The Providence Infirmary.—The Mobile Medical Society.—The State and County Boards of Examiners.

MOBILE, August 27, 1883.

The Medical College of Alabama, located in this city, dates its existence back to 1859, and will therefore, in another year, be entitled to celebrate its quarto-centennial anniversary.

The eminent and lamented Dr. J. C. Nott, or, as he was familiarly styled among his professional brethren, “The Old Roman,” was, perhaps, the leading spirit in the conception and inauguration of the enterprise.

Possessing a vigorous and broad intellect and entertaining comprehensive views on all subjects, manifesting throughout his professional life a genuine devotion to the science of medicine and a princely courtesy for those engaged either in the practice or study of it, and withal full to overflowing of personal magnetism, he was pre-eminently the man to take the lead in founding and organizing an institution of medical learning.

As a scientist and surgeon, his fame was both extensive and brilliant. In the former capacity he was best known as an ethnologist, and as the author, in connection with George R. Gliddon, the distinguished Egyptologist, of “Types of Mankind” and “Indigenous Races of the Earth”—both works having attracted much attention both in this country and in Europe. Many other contributions to the medical and scientific press helped to give him prominence as a man of learning. As a surgeon, his fame was unsurpassed in the South or Southwest except by that of the distinguished Dr. Warren Stone, of New Orleans, between whom and Dr. Nott the warmest friendship existed, each according to the other great skill and talent.

His reputation as a surgeon, as a matter of course, fixed his position as professor of surgery in the formation of the first faculty.

Those who sat under his teachings will remember the force and distinctness with which he enunciated the principles, and the skill and dexterity with which he executed the practice, of the great art of surgery.

In the work of organizing the college he received the hearty co-operation and assistance of the profession generally of Mobile, and the material aid of many of the citizens. Among the former may be mentioned Dr. F. A. Ross, Dr. W. H. Anderson, Dr. George H. Ketchum, Dr. J. F. Hustis, and Dr. G. Owen, all of whom became members of the original faculty, and have so continued to the present time.

Dr. Ross, after having ably filled the chair of materia medica and therapeutics for a number of years, offered his resignation, which was accepted, and he was placed on the emeritus list. He was worthily succeeded by Dr. E. H. Fourier, who, in his teaching, endeavors to make philosophy and medicine inseparable companions.

Dr. Anderson and Dr. Ketchum continue to fill their original positions.
CORRESPONDENCE.

From 321 chairs—those of physiology and the theory and practice of medicine, respectively—than whom it would be difficult to find more fluent or able lecturers.

Dr. Henstis was transferred, a number of years ago, from the chair of anatomy to that of surgery, where he found a wider field for his skill and learning.

Dr. Owen long since won promotion from the demonstratorship of anatomy to the professorship of obstetrics and diseases of women and children.

At a little later period than the first organization, Dr. E. P. Gaines became a member of the faculty, and so continues, as professor of physical diagnosis and diseases of the chest—a field to which he brought great fitness, experience, and enthusiasm.

The names of Dr. J. T. Gilmore and Dr. Jerome Coehran may be mentioned as having been connected with the faculty—the former, as one of the most brilliant and rising surgeons in this country, who fell an early victim to disease; the latter in the capacity of professor of chemistry and hygiene, now the able and efficient Health Officer of the State, and the leader in a great reformation which has been wrought in the medical affairs of Alabama.

In aid of the college the State made a handsome appropriation, which amount was supplemented by liberal contributions from certain citizens of Mobile and members of the original faculty—the aggregate having been ample sufficient to erect a commodious and imposing college building, and to equip it with complete and admirable appointments.

When the building was approaching completion, Dr. Nott, supplied with abundant funds, proceeded to Europe and expended more than fifty thousand dollars in the purchase of a museum, a collection of materia medica specimens, and such apparatus and appliances as were necessary for teaching the science of medicine.

In all these respects, therefore, the institution was placed, at the very outset, upon a superior plane of equipment for fulfilling the purposes of its foundation.

With an interregnum in its existence during and immediately after the Civil War, the college has gone on doing what it could to educate young men, and has always held, and still holds, itself ready to unite with the other colleges of the country in any effort looking to the elevation of the standard of medical education, or the lengthening of the time of study, and the adoption of a graded course.

Its corps of teachers now consists of eleven professors and lecturers, and five adjuncts and demonstrators. Endeavoring to keep pace with the growth of medical science, it added, several years ago, to its curriculum of study the special branches of diseases of the eye and ear, and last year those of histology and pharmacy. An admirable laboratory has been arranged for teaching microscopy, and is supplied with a sufficient number of Hartnack's microscopes. The clinical facilities are convenient and ample.

The City Hospital, the charity provided for the indigent sick of the city and county, is under the entire control of the faculty, and its wards, where clinics are daily held, are thrown freely open to the students.

The Providence Infirmary, an institution under the care of the Sisters of Charity, and combining elegance and comfort in its appointments, is thrown open in the same free way to the class.

On three days of the week clinics are held at the college for out-door patients, including diseases of the chest, diseases of children, and diseases of the eye and ear. Both here and at the hospital, every effort is made to bring the students in close contact with the sick, and to encourage them to make examinations for themselves.

While utilizing all clinical material to the best advantage, didactic teaching is neither underrated nor lost sight of. From five to seven lectures are given daily at the college during the session, which are intended to convey that sort of instruction without which clinical teaching would be of little value.

As one of the auxiliaries, so to speak, of the college, may be reckoned the Mobile Medical Society—an organization that augments the former by about twenty years, and whose vigor and usefulness continue to improve with advancing age.

It comprises in its membership four-fifths of the active practitioners of the city, and holds weekly meetings in a well furnished hall provided for its exclusive use. On an average, these meetings do not fail once in the year. At every alternate meeting "Reports of Cases" is made the order of business, and each member is allowed and expected to report the general character of sickness which has fallen under his observation for the previous two weeks, and to detail the histories of cases of any special interest.

The relating of such cases often arouses animated discussions, and, in the analysis reached thereby, obscure points in diagnosis are cleared up, and valuable suggestions as to treatment are made.

At the intermediate meetings papers are read, or discussions held upon definite medical subjects, in which the members generally participate. Thus the business alternates from week to week, and goes on from year to year.

It will be seen that attendance on these meetings will enable one to keep himself informed not only as to the character of prevailing sickness, but as to the histories of all the important and interesting cases occurring in the practice of a large number of physicians. The papers read and the discussions held serve to widen the information and sharpen the argumentative powers of the members.

The students of the college are invited to these meetings with the hope that, by becoming familiar with the manner in which the business of a well-organized medical society is conducted, they will appreciate the advantages of such organizations, and either desire to participate in them where they already exist, or take the lead in organizing new societies.

In Alabama and Mississippi the troubles of the young M. D.'s are not over when the colleges have conferred diplomas upon them.

Before they can be allowed to enter into practice they must undergo an examination by the State.

In Alabama this examination is held either by the State Board of Medical Examiners, elected by the State Medical Association, or by a county board of examiners, elected by the county medical societies.

The examinations, partly oral and partly written, are rigid, and are made to cover the whole range of medicine.

This law has now been in operation some five years or so, and already has markedly improved the tone of the profession, and has entirely banished quackery from the State.

In Mississippi the arrangement of the examining boards is somewhat different from that in Alabama; but there, too, the character of the examinations is said to be rigid and searching.

The instances are already numerous, and growing more and more important, in which a young doctor—returning with diploma in hand, honors upon him, and visions of fees and patients before him—has found himself ingloriously "plucked" by one of these overhanging boards, and has been compelled, in consequence, either to pursue his studies further, or to emigrate to some State where a diploma, however undeserved, is a license to practice.

So far, none of these instances have occurred to the alumni of the Medical College of Alabama, and, if she continues to be wise, the contingency of their happening in the future will be reduced to a minimum.
NEW YORK, SATURDAY, SEPT. 22, 1883.

LAST YEAR'S EPIDEMIC OF DENGUE IN BERMUDA.

In January last the Governor of the Bermuda Islands appointed commissioners to inquire into the origin and history of the epidemic of dengue which prevailed in the islands in 1882, and the points they were instructed to consider were: 1. The origin and course of the epidemic. 2. Whether the quarantine laws or regulations required amendment, and in what manner. 3. Whether the administration of those laws called for amendment, and in what direction.

The commissioners find that the epidemic had its origin in H. M. S. Sparrowhawk, a small wooden surveying vessel which left Nassau, N. P., for Bermuda, with a promiscuous crew of eight or nine men, on the 22d of July, 1882, and arrived at Hamilton on the 31st of the same month. Dengue was prevalent at Nassau when the Sparrowhawk left that port, her commander having had the fever there. During the passage one of the crew had the disease. On the 4th of August another one of her men was seen by the surgeon of the Terror, and this was believed to be the first case in Bermuda. The fever subsequently appeared among the persons employed in the dock-yard, on the 10th or 11th of August, and the outbreak was connected with the Sparrowhawk, as it is in evidence that before her arrival the health of the island and of the dock-yard was good. The commissioners take up this question in some detail, and find that the Sparrowhawk was hove down to be cleaned in the camber, close under the bows of H. M. S. Spitfire, which up to that time had been in a healthy state, and that the men on board the two ships mingled together freely, those from the Spitfire having been employed in cleaning the Sparrowhawk. They also slept at night within a few feet of the latter vessel.

Within a few days after the 10th of August several men were sent from the Spitfire to the Royal Naval Hospital, and, the disease not being recognized, they were isolated in the fever ward. The fever spread rapidly from the men thus brought in to the medical officers and nurses in the hospital, from the latter to their families in their immediate neighborhood, and from the medical men and attendants to the other patients in the hospital, sixteen of whom, out of nineteen who were in the hospital for other complaints, contracted it. The same fever broke out among the crews of the Urgent and Terror, and they were hulked on board the Irresistible, together with the crew of the Sparrowhawk, August 18th. About the 16th of August an officer of the dock-yard, whose duties took him on board the Sparrowhawk, contracted the fever, and all his family were attacked with it. While the fever was prevailing, H. M. S. Foam arrived from Halifax with a healthy crew. She brought a prisoner for the naval prison at Hamilton. In forty-eight hours after being placed in the cell he was taken with the prevailing disease. There was no other person in the prison at the time, but there had been fever in it, and the cells had been whitewashed. From the dock-yard the fever spread rapidly, first to Somerset, the part of the colony nearest to the Naval Hospital, and then to the other parts of the islands, and in four or five weeks after the arrival of the Sparrowhawk it prevailed generally throughout the colony. One medical man who visited the Royal Naval Hospital early in October, to ascertain the nature of the fever, about which very exaggerated reports had appeared in foreign papers, states that he himself had an attack four or five days after visiting the hospital, and then his family was attacked, there having been no fever previously in his neighborhood.

The commissioners remark that no one who examines the evidence can doubt that the original focus of the disease was the dock-yard, that it gradually but rapidly traveled from that center to all parts of the colony, and that there is nothing to account for its original appearance at that center but the sanitary state of H. M. S. Sparrowhawk and her crew. While there was no fatality attending the disease, the commissioners believed it to be infectious and contagious. It was not regarded as having any connection with yellow fever, although the fact is mentioned in the report that some practitioners regard it as a modified form of that disease. The commissioners found that the administration and the quarantine laws were in general efficient, and that they would prove adequate to prevent epidemics of dangerous fevers if rigidly enforced.

A new feature in this report is a proposition to divide infectious diseases into two classes. The report says: "The commissioners think it deserves consideration, whether infectious diseases may not be classified under two heads, distinguishing those most likely to be imported, and exceptionally infectious, from others of either a less infectious or less serious nature, or with respect to which the danger of importation is smaller. To the former class the most rigid quarantine regimen should be applied. It might suffice with the other class to enforce precautions and restrictions of a less stringent nature."

The classification proposed for consideration is:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yellow fever</td>
<td>Typhus</td>
</tr>
<tr>
<td>Scarlet fever</td>
<td>Typhoid or enteric fever</td>
</tr>
<tr>
<td>Small-pox</td>
<td>Relapsing fever</td>
</tr>
<tr>
<td>Cholera</td>
<td>Measles</td>
</tr>
<tr>
<td>Diphtheria</td>
<td>Chicken-pox</td>
</tr>
<tr>
<td>Plague</td>
<td>Dysentery</td>
</tr>
<tr>
<td>Dengue</td>
<td>Croup</td>
</tr>
</tbody>
</table>

"Whooping-cough."

"The class A, the report continues, "comprises those diseases against the importation of which it is impossible to be too guarded, and class B those which require great vigilance, but not the same severe restrictions."

In regard to the general administration of quarantine the report says: "The commissioners are far from thinking that a
mere categorical examination of this kind would be any sufficient substitute for the intelligent investigation of a vigilant health officer, or that the officer should be thereby relieved from the duty of making a thorough examination of the sanitary condition of a ship as required by law. But circumstances elicited in evidence before the Commission show that such a mechanical inquiry as is here suggested may prevent serious oversights and hasty conclusions."

It appears from the foregoing that the opinions of Lord Granville relative to the efficacy of quarantine, or, rather, his belief in its inefficacy, are not shared by the British colonies near infected regions. No American port has ever yet gone so far in observance of quarantine as to consider dengue necessary to be excluded.

THE INDIANA STATE BOARD OF HEALTH AND ITS LATE SECRETARY.

A State board of health without a quarrel on its hands is getting to be an uncommon spectacle. The Indiana board has become involved in a controversy with an Indianapolis physician who was formerly its secretary, and, we infer, still considers himself as secretary de jure, although the board removed him last March, and chose a successor, who entered upon the duties of the office. The board furnished the deposed secretary with a written statement of the reasons for his dismissal—substantially, that his penmanship was too bad; that his statements as to the business and work of the board had been "wavering, loose, and indirect," so that he had kept the board uncertain as to what he had done and what he was going to do; that his minutes had been kept incorrectly, making it appear in some instances that the board had done things it had not done, that he had hired a clerk without the approval of the president of the board, as required by law, and at an extravagant salary; and that he had committed the board to needless expenditure for furniture and supplies for its office. But what brought things to a climax, the board aver, was the secretary's refusal to resign at a particular time, as he had promised to do.

The secretary naturally felt annoyed at the turn affairs had taken, but, very sensibly declining to go to law over the matter, has relieved his mind by a written defense read before the Indiana State Medical Society and entered on the society's minutes. In this vigorous document the secretary frankly admits and laments his lame penmanship, but hints that he has no ambition to become a writing-master, and avers that the president of the board is not a paragon in orthography. He states that his minutes were invariably approved by the board, whereas, if they had been of the character alleged, the board ought not to have taken such action on them. As to the clerk he hired, he maintains that one had to be had, and that the board practically justified his action by finally employing a more expensive clerk than the one in question. He adds that some of the office supplies that the board now profess to have considered unnecessary they took quite a fancy to at the time, several of the members taking a portion away with them for their own use. His promise to resign, he maintains, was con-
ditional, and he states that the condition was violated by some member of the board. Finally, he hints that a snare was laid to convict him of negligence or incapacity by causing a stenographer to claim his warrant for compensation for reporting the proceedings of the board-meeting at which the secretary was given a hearing; the stenographer submitting to him the notes of certain proceedings in court involving some matters connected with horses, in lieu of the real notes of the meeting.

It seems that there had been trouble between the secretary of the board and the Secretary of State, who was also a physician, and that the latter finally succeeded to the former's position, and the deposed official hints rather broadly that it was to lead up to this change that his own resignation was requested.

Without assuming to solve the merits of the dispute, we may characterize the secretary's defense as very entertaining matter. We must add our regret, however, that the occasion that called it forth should ever have arisen.

A SOCIETY OF MEDICAL CLIMATOLOGY.

In our news columns the reader will find a notice of a meeting of gentlemen well known in connection with the study of climate in its bearings on disease, particularly pulmonary disease, to be held in New York on the 25th inst. It is encouraging to note that those who have signified their intention of joining in the object of the meeting, the organization of a society for the purpose of facilitating and systematizing the pursuit of investigations in this direction, belong in widely distant parts of the country, many of them living in localities much resorted to by pulmonary patients. The field in question seems one of the most promising for "collective investigation," and it is to be hoped that, being brought face to face with each other, and perhaps held somewhat in check by those of their associates who are under no bias in favor of one health resort as opposed to another, the members who come from the various localities claiming the approval of the profession may really be made to see that their natural preferences must be cast aside as the first step in an intelligent and useful study of the subject they have in hand.

We may be allowed to suggest that the title proposed for the new society—"Association for Diseases of the Respiratory Organs and Climatology"—is somewhat cumbersome and illogical. So far as we are aware, diseases, whether those of the respiratory organs or those of any other sort, do not congregate and form associations, and if they did they would scarcely admit climatology to membership, although they might make it a patron. Furthermore, the name is too narrow in its scope. If the machinery necessary for studying the influence of climatic conditions on the human system is really to be set in motion, it seems a pity that no other departments of medicine than that relating to pulmonary diseases are to be benefited. But, whatever title the organization may determine to be known by, we have no doubt that its work will prove of signal advantage to medicine.
AN UNFOUNDED CHARGE OF MALPRACTICE.

The tendency to conceal criminal abortions on the part of the victims' relatives is a well-known impediment to the course of justice, and a serious hindrance to the operation of laws designed to do away with the foul blot on our civilization involved in the practice of destroying embryonic life. Irritating and discouraging as it is to bring up continually against this obstacle, its foundation in a feeling of honor and loyalty can not but be recognized nevertheless. A case has lately happened, however, in which the opposite course is reported to have been taken under circumstances that render it not only surprising but offensive. It seems that a woman of questionable repute, being at the same time a femme entretene and a so-called clairvoyante, had a daughter whom she treated in such a way as to alienate her, and cause her to take refuge in the family of a gentleman with whose daughter she had contracted a friendship. There is no reason to suppose that her life was not perfectly correct, but she was attacked with uterine cancer, and by the time adequate medical attendance was secured it was found that the disease had advanced to a degree past all hope from surgical interference. Her death was therefore looked forward to as almost certain to take place within a few months, and last month she died. A proper certificate was given by her physician, and the poor girl was buried.

Now the unnatural mother appears upon the scene, professing to suspect that her daughter died, not of cancer, but of the results of a criminal abortion, and intimating that there had been improper relations between her and the gentleman who had kindly taken her into his family. As may well be imagined, this course on the part of the mother is not the outcome of any conscientious desire to see justice done, but seems to be prompted by mercenary motives, and to be part of a plot to break a will the daughter had made, the latter having, with the assistance of her protector, found her father, whom she had been taught by her mother to consider dead, and the father having since died and left her some property now in litigation.

The woman having laid her suspicions before a coroner, that officer ordered an exhumation and a medical examination of the body. Although some surprise has been felt that he should have taken that course on such grounds, we are unable to see how he could reconcile it with his duty to do otherwise, since an officer of the law is scarcely at liberty to pronounce against an accuser's good faith in advance, be the person never so disreputable. Apart from this consideration, too, in no other way could the poor girl's reputation, and the conduct of her friends and her medical advisers, be more cogently vindicated.

The lesson to be learned from the revolting incident is, that in view of the extreme reluctance with which criminal abortion is admitted by the kindred of its victims, the public is only too likely to put unquestioning trust in accusations of that sort coming from a relative; and the danger is, that a class of robbers will arise capable of seizing upon this weakness on the part of the public to further their own base purposes. If this fear should be realized to any great extent, of course there will be a reaction; accusations made in good faith will then have ceased to have their present force, and convictions for criminal abortion will become even more difficult than now.

MINOR PARAGRAPHS.

THE MISSOURI STATE BOARD OF HEALTH.

The Board of Health of the State of Missouri, lately organized under an act approved during the current year, includes the following members: Dr. E. H. Gregory, of St. Louis, president; Dr. G. M. Cox, of Springfield, vice-president; Dr. J. C. Hearne, of Hannibal, secretary; Mr. G. T. Bartlett, of Poplar Bluff; Dr. W. B. Conery, of St. Louis; and Dr. H. F. Hereford, of Kansas City. The late Dr. P. D. Yost was a member of the board at the time of its organization. We have not learned that an appointment has been made to the vacancy caused by his death. An appropriation of $6,000 constitutes the entire pecuniary resources of the board, and the secretary is the only salaried member, the others simply drawing upon the fund to cover expenses incurred in their official work. It strikes us that the appropriation is scarcely adequate to the sanitation of the great State of Missouri.

THE BOSTON MEDICAL AND SURGICAL JOURNAL.

It is seldom that a summer number of a medical journal, or any other number for that matter, contains such excellent editorial writing as is to be found in our contemporary's issue of September 6th. We allude more particularly to its leading article, "Medical Men and the 'Classical Fetish.'" We may add that we share the writer's feeling of regret that classical studies "are losing the place which they formerly held as the only orthodox gateway to our profession."

AN AKWARD TRIBUTE TO THE FOUNDER OF THE "LANCET."

In a leading article in a recent issue of the "Lancet" we find mention of a certain practical reform which the founder of that journal advocated, in his peculiarly telling style, fifty years ago, but which, it seems, has not yet been accomplished. "Mr. Wakley," the article goes on to say, "was a practical man. He did not trouble himself with ideal grievances and reforms. Hence every reform but this, which his clear vision saw to be necessary, has been achieved." Does the writer really mean that the reform in question has failed because the late Mr. Wakley was a practical man, and did not trouble himself with ideal grievances and reforms?

AN EVASION OF QUARANTINE.

According to the "Sanitary News," the captain of a vessel that had been quarantined off New Orleans lately succeeded in reaching the city by a roundabout journey that suggests to the "Sanitary News" a weak point in quarantine law. It seems that the mariner in question, finding no possibility of reaching the city directly from the quarantine station, took passage for New York by steamer, and then pursued his journey to New Orleans by land.

A NEW SOURCE OF DANGER FROM INFECTION.

It is well known that in articles of chinaware that have been in use for some length of time the glazing shows a network of cracks, thus allowing liquids to penetrate into the porous material of the ware. In a recent communication to the French Académie des Sciences, M. Peyraudon expressed the opinion that minute organisms might readily find lodgment within the crevices of china vessels, and be taken into the system, with the consequent danger of communicating infectious diseases.
A NEW SPANISH JOURNAL.

The multiplication of Spanish medical journals of late is remarkable. The last that has come to our notice is entitled "El Ensayo Médico," published at Caracas, and edited by Dr. Dorotheo De Armas, Dr. F. Monroy Gonzalez, and Dr. David Lobo. It is an eight-page monthly.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending September 18, 1883:

TYPHOID FEVER.—It will be seen by the foregoing table that in the two weeks ending September 18th there have been reported one hundred and fifty-two cases of typhoid fever and forty deaths. The comparative statistics of 1882 and 1883, as given in the report of Dr. Day, the Sanitary Superintendent, show a marked increase of the disease during the year over that for 1882. In January, 1882, there were forty-six cases, and forty-seven during the corresponding month of this year. In July, 1882, there were forty cases, and ninety-three in July, 1883. In August, 1882, there were ninety-six cases, and during last month there were two hundred and forty-four. The Board of Health has issued a circular calling attention to Dr. Day’s report, and urging the adoption of means to prevent a further spread of the fever.

YELLOW FEVER.—A violent outbreak has occurred in Guaymas, a sea-port town in Mexico. Twenty-six deaths were reported up to the 12th inst., amongst which were those of several Americans. Reports from Hermosillo and Mazatlan state that the fever is raging in those towns.

Mail advices from Rio Janeiro show that the disease still prevails there, though confined mostly to the shipping.

On Friday three new cases were reported from Pensacola, with one death. On Monday there were four new cases and three deaths, and on Tuesday no new cases but one death. Pensacola has quarantined against Mobile.

A brig, which had seven cases of yellow fever on board while at Havana, was reported to have sailed for Philadelphia on the 12th inst.

The quarantine has been removed from Cape Charles, Virginia.

MALIGNANT DIPHTHERIA is raging in a portion of Hartford, Conn., where there is a quantity of stagnant water. Several deaths have already been reported.

SMALL-POX has made its appearance in Nashville, Tenn., and several deaths have occurred. Unsuccessful efforts have been made to have two or three patients removed to the pest-house.

LEPROSY AT SAN FRANCISCO.—A case of leprosy was brought to San Francisco in a steamer which arrived from Honolulu last week. The quarantine officers refused permission to land.

PLEURO-PNEUMONIA in PENNSYLVANIA.—Pleuro-pneumonia has made its appearance among the cattle in the counties of Delaware, Chester, and York, and about three hundred and fifty animals have been killed to prevent a further spread of the disease, which it is thought is now under control. The disease has been traced to a herd of cattle brought from Baltimore and sold in West Chester.

THE FOOT AND MOUTH DISEASE seems to be increasing in England, as shown by late returns from the agricultural districts.

THE INSANE OF LYNN, MASS.—The overseers of the poor of Lynn intend visiting the State hospitals with a view to ascertain whether a portion or the whole of the fifty insane persons from that city can not be more economically cared for at the Lynn Almshouse. The average cost of maintenance at the hospital is about four dollars a week for each individual, while in the almshouse the cost is only $2.30 a week.

THE CONNECTICUT HOSPITAL FOR THE INSANE.—At a quarterly meeting of the trustees of this institution, held on Thursday, the 13th inst., it was decided that at the close of the current quarter the rate of board shall be reduced from $4 to $3.75 a week. It is estimated that this will save the State several thousand dollars a year. There are at present in the hospital eight hundred and fifty seven patients, comprising the “pauper” insane, the “indigent” insane, for both of which classes the State pays one half, the “soldier” insane, cared for wholly by the State, and the insane who are supported by their friends.

AN ASSOCIATION FOR DISEASES OF THE RESPIRATORY ORGANS AND CLIMATOLOGY.—A meeting for the purpose of organizing this association will be held in the parlors of the Academy of Medicine, in this city (12 West Thirty-first Street), on Tuesday, September 25th, at 10 a.m. The circular states that it is of the utmost importance that as many colleagues as possible should attend this preliminary meeting. The following gentlemen have signified their intention of becoming members of the association: G. M. Garland, M.D., F. F. Knight, M.D., F. C. Schattuck, M. D., Frank Hooper, M. D., of Boston; H. D. Didana, M. D., of Syracuse; A. L. Loomis, M. D., James R. Leaming, M. D., Beverley Robinson, M. D., F. Darwin Hudson, M. D., D. M. Cum- mann, M. D., J. Hilgard Tyndale, M. D., J. W. Gletschmann, M. D., of New York; E. T. Brune, M. D., J. C. Wilson, M. D., J. Solis Colien, M. D., C. Carl Seiler, M. D., J. B. Walker, M. D., of Phila- delphia; B. F. Westbrook, M. D., Samuel G. Armor, M. D., P. H. Kretzschmar, M. D., of Brooklyn; E. Fletcher Ingalls, M. D., H. A. Johnson, M. D., of Chicago; W. C. Glasgow, M. D., of St. Louis; Richard McSherry, M. D., Frank Donaldson, M. D., of Baltimore; A. Y. P. Garnett, M. D., of Washington; W. H. Geddings, M. D., of Aiken; F. D. Lente, M. D., of Palatka; Charles Denison, M. D., of Denver; T. B. J. Talbot Jones, M. D., of St. Paul; E. L. Sharley, M. D., of Milwaukee; M. F. Coomes, M. D., of Louisville; E. W. Schaffler, M. D., of Kansas City; D. N. Kinsman, M. D., of Columbus; Boardman Reed, M. D., of At- lantic City.

COLLEGE OF MIDWIFERY.—The following changes have been made in the faculty : Dr. Sarah E. Post has been appointed Professor of Physiology, in the place of Dr. John Aldsorth, who has taken the chair of Diseases of Pregnancy and Parturition. Dr. Henry F. Hesset has been appointed Professor of Clinical Midwifery and German Instructor in Obstetrics. The sessions have been extended to six months—three months of didactic instruction and three months of clinical work.

Professor C. F. Chandler has signified his acceptance of the nomination to be a member of the commission to be appointed by the President to investigate the alleged prevalence of di-ease among swine.

ST. BARTHOLOMEW’S HOSPITAL, LONDON.—Dr. Dyce Duckworth has been appointed a physician to the hospital, to fill the
LETTERS TO THE EDITOR.

Erysipelas Migrans.

337 West Nineteenth Street, N. Y., September 7, 1853.

To the Editor of the New York Medical Journal:

Sir: Dr. H. F. Walker’s remarks on erysipelas migrans, made before the New York Medical and Surgical Society, April 28, 1853, remind me of a somewhat similar case which came under my care some six years ago in England. It was that of a child between eight and nine months old. The erysipelas started in the right calf and an abscess formed, which I opened; it then attacked the same thigh, shifted from that to the left leg, and thence to each arm in succession, and then returned to the spot whence it started, forming another abscess, which I also opened. One feature in the case was the little apparent suffering the child seemed to have during this time—a period of twelve days. The treatment adopted was: Linseed meal poultices, made in extract of poppies solution, applied to the parts attacked, and internally some compound rhubarb mixture—thrice daily. The child recovered, and has, so far, had no renewal of the attack—i.e., to the beginning of last year, when I left England. I am yours, etc.,

John C. White, L. R. C. P. Edin.

The Rubber Coil and Other Matters.

Junction, Pulaski County, Ill., September 7, 1853.

To the Editor of the New York Medical Journal:

Sir: Having found it very difficult to apply ice or ice-water with sufficient regularity to keep down the heat in lacerated wounds, and having seen in your paper reference to the “ice-coil,” I wish to ask if there is in your city some well-approved method of applying cold in such cases. Also to report the case of a man, some sixty-eight or seventy years of age, who last year was treated for malarial fever, who, on partial recovery, was affected with pain in the arm, which his physician regarded as rheumatism, but found no means to alleviate.

Though otherwise in moderate health, walking and riding about his farm, he has not had his hand to his face in a twelve-month.

I understand some fifty grains of quinine were given in a day during the fever, and that his physician proposed to give chloroform, and forcibly bend the arm.

There are, too, in this country a number of persons who
never sleep, notwithstanding pounds of bromides, chloral, and cannabis indica, and whose constant cry is blessings on the man's head who for us would "invent sleep," and this, too, after Dr. Sell, of your city, has written so much about the "eat cure" for inebriates of various kinds. Can it be possible that virtue attaches to such things?

In my own person I received a poisoned wound many years ago, which resulted in inflammation of the veins of the leg, and paralysis. The superficial veins of that side have remained varicose, and two years ago I had rheumatism of that knee, with extreme pain in the popliteal space, apparently of the returning vessels. Episcleritis, repeated in succession and continued for days, alleviated the suffering, which otherwise would have been unbearable, and set me on my feet again.

Later a horse kicked me and broke the fibula, and made an external wound, which has about closed, but which was accompanied by an intensity of pain and heat unparalleled in my experience. It was here I found the use of ice so inconvenient, but yet so essential to comfort.

I am waiting the union of the broken bone, and find my physicians divided about the propriety of my taking iodide of potash, there being numerous little sores on the limb, and some swelling of the glands in the groin and in the axilla, as was true in the first case of the poisoned wound.

If your polyclinics meet with any more knotty cases than this, they deserve our sympathy. Respectfully,

JAMES H. CRAIN, M. D.

We think our correspondent would find the coal a satisfactory means of applying either heat or cold. Possibly some of our readers may be able to advise him in regard to his present troubles.

Proceedings of Societies.

AMERICAN GYNECOLOGICAL SOCIETY.

The eight annual meeting was held in the hall of the College of Physicians, in Philadelphia, Tuesday, Wednesday, and Thursday, September 18, 19, and 20, 1888, the President, Dr. Gilman Kimball, of Lowell, Mass., in the chair.

First Day—Morning Session.

The meeting was called to order at 10.30 A.M.

The following-named Fellows were present during the day:
Dr. Gilman Kimball, of Lowell, Mass.; Dr. Foyle Barker, of New York; Dr. Robert Battey, of Rome, Ga.; Dr. B. B. Brown, of Baltimore; Dr. William H. Byford, of Chicago; Dr. John Byne, of Brooklyn; Dr. Henry F. Campbell, of Augusta, Ga.; Dr. James R. Chadwick, of Boston; Dr. Edward L. Deur, of Philadelphia; Dr. Thomas Addis Emmet, Dr. Frank P. Foster, and Dr. Walter R. Gillette, of New York; Dr. William Goodell, of Philadelphia; Dr. William T. Howard, of Baltimore; Dr. James V. Ingham, of Philadelphia; Dr. A. Reeves Jackson, of Chicago; Dr. Joseph Taber Johnson, of Washington; Dr. William T. Luse, of New York; Dr. George H. Lyman, of Boston; Dr. Matthew D. Mann, of Buffalo; Dr. C. D. Palmer, of Cincinnati; Dr. Theodore Parvin, of Philadelphia; Dr. Theodore A. Ramay, of Cincinnati; Dr. John C. Reeves, of Dayton, O.; Dr. John P. Reynolds, of Boston; Dr. Albert H. Smith, of Philadelphia; Dr. R. Stansbury Sutton, of Pittsburg; Dr. Ely Vande Warker, of Syracuse; Dr. H. P. C. Wilson, of Baltimore; and Dr. E. Wilson, of Philadelphia.

The Address of Welcome was read by Dr. Edward L. Deur, of Philadelphia, who dwelt briefly upon the scientific importance of the annual meetings, but emphasized also the value of the social element.

Invited Guests.—On recommendation of the Council, the following-named gentlemen were invited to attend the meeting as guests of the society: Dr. Alfred Still, president of the College of Physicians of Philadelphia; Dr. William M. Welsh, president of the Philadelphia County Medical Society; Dr. Richard A. Creekman, president of the Obstetrical Society of Philadelphia; Dr. James Tyson, president of the Pathological Society of Philadelphia; Dr. Robert F. Harris, of Philadelphia; and Dr. I. R. PAGE and Dr. Robert T. Wilson, of Baltimore.

Superinvolutions of the Uterus.—Dr. Joseph Taber Johnson, of Washington, read a paper with this title, in which, after summarizing the writings of Sir J. Y. Simpson and other authors upon the subject, he embodied notes of four cases that he had met with in his own experience. Care should be taken not to confound such cases with those of atresia of the uterine canal. General invalidism was not a necessary result of the lesion, as was shown in one of the cases narrated, in which the patient appeared to be in blooming health. In cases in which there was impairment of the general health, the use of galvanism, ergot, strychnine, and various tonics would correct that condition, but the problem was, to restore the uterine functions to their normal condition, and especially to overcome sterility. In this attempt the author’s experience had not been encouraging. In one instance phenomena resembling the early signs of pregnancy followed, but they proved illusory, and impregnation was found not to have taken place. Dr. Johnson was not inclined to agree with Dr. Walter Coles, of St. Louis, in considering the lesion to be properly one of post-partum atrophy, rather than of superinvolutions. In the treatment, galvanic stem pessaries were recommended by many authors, but it was admitted in general that restoration of the organ to its natural condition could not be accomplished, in marked cases, by this or any other measure.

Dr. Foyle Barker, of New York, remarked, in regard to the term “superinvolutions,” that he thought it might properly be applied to excessive involution after enlargement of the uterus from any cause, as from fibrous tumors, and need not be limited to the hypertrophy due to pregnancy. It was difficult to estimate the frequency of its occurrence, but he saw from one to three cases every year—mostly in consultation. In deciding whether or not, in any given case, there was a chance of producing improvement by treatment, he had been in the habit of guiding himself by the state of the ovaries in regard to the function of ovulation. If there were well-marked signs of ovulation, the prognosis was reasonably good. The speaker related cases illustrating this statement.

Dr. A. Reeves Jackson, of Chicago, had seen but a single case, and that of doubtful diagnosis, and had been surprised to find now that the occurrence of the condition was considered so common. In his case there was stenosis of the uterine canal. The use of a galvanic stem pessary for several months was productive of no benefit. The speaker was inclined to regard Dr. Barker’s suggestion as to the prognosis as of very great practical importance.

Dr. Ely Vande Warker, of Syracuse, N. Y., called attention to the frequency of superinvolutions limited to the cervix, due, in his experience, to laceration of the cervix, and generally confined to the posterior lip. Perhaps the lesion was due to cicatricial contraction.

Dr. H. P. C. Wilson, of Baltimore, had rarely met with superinvolutions following gestation—not more than two or three
times in his whole practice. Dr. Barker’s view as to prognosis commended itself to him, and had been borne out in his experience.

Dr. Robert Battey, of Rome, Ga., spoke of superinvoluption as a very common result of oophorectomy, often very marked in degree. Lack of proper ovulation was, he thought, the cause of the trouble in the class of cases referred to by the reader of the paper. He could not agree with Mr. Lawson Tait in regarding the ovarian function as of little governing importance in the physiology of menstruation. In regard to treatment, he had found electricity, passed from the sacral region through to the iliac region or the vagina, the most beneficial agent, and with its use he usually combined dilatation of the uterine canal with tents.

Dr. William H. Byford, of Chicago, was inclined to regard superinvoluption as one of the stages of atrophy. We should distinguish, too, between diminution of the size of the uterus alone and such reduction associated with other atrophic or senile changes in the pelvic organs, especially the ovaries. In simple uterine cases, stimulation by some foreign body might be productive of benefit.

Dr. Henry P. Campbell, of Augusta, Ga., did not think the condition was necessarily due either to the discontinuance of ovulation or to atresia. He had known it to result from overdistension of the uterus due to dropsy of the amnion, of which he related an interesting example. This result, he thought, was due to injury to the muscular structure, as happened to the bladder in cases of over-listenction.

Dr. Johnson closed the discussion by expressing his agreement in the view as to prognosis given by Dr. Barker.

The Importance of Cleanliness in Surgical Operations was the title of the next paper, by Dr. R. Stansbury Sutton, of Pittsburgh, Pa. The author drew a striking picture of the effects of surgical methods in vogue prior to the past twenty-five years in thwarting the efforts of nature in the repair of injuries. The ancients governed themselves by the theory that everything bad came from within; consequently, purgation of one sort and another was thought to be of the first necessity. We, on the other hand, regarded the malignant influences acting upon wounds as derived from without, and took all possible pains to exclude germs and to maintain scrupulous cleanliness. Reviewing the chief modifications of the Listerian method of treating wounds, and according full credit to the method, the author thought it abundantly established, by the experience of Dr. Keith, Mr. Tait, and Mr. Bantock, that, in some of its features at least, it was better to modify it in abdominal surgery. Those who found great advantages in Listerism were those whose practice before they had adopted it was not characterized by the cleanliness that was one of its cardinal points; those who regarded it as of no assistance were those who already paid so much attention to cleanliness that they did not stand in need of the improvement it involved. A specific dressing was not needed in all cases; cleanliness, however, should always be secured. The reader then gave detailed directions for the maintenance of cleanliness.

At the suggestion of Dr. Barker, Dr. S. D. Gross, of Philadelphia, was invited to open the discussion, but declined to do so.

Dr. Thomas Andrews Emmet, of New York, was fully aware of the necessity of cleanliness. He placed more reliance on soap and water than on any germicide. Dr. William T. Lusk, of New York, thought Dr. Sutton’s directions as to cleanliness would satisfy the most ardent supporter of Listerism. He could not admit that the spray was so useless or so dangerous as it was getting to be common to represent it. In operations upon parts reached through the vagina, the advantages to be derived from preliminary disinfecion of the vagina were most decided. Some years ago the speaker did the first successful ovariotomy done in Bellevue Hospital—some years ago, and in a surgical ward—relying on Listerism. In this “tainted hospital” he still performed ovariotomy without hesitation, and with good results, thanks to Listerism.

Dr. H. P. C. Wilson coincided with Dr. Lusk’s views in regard to Listerism and to the spray. It was somewhat diabolical, he thought, for the great ovariotomists to decry Listerism, while daily using all of Mr. Lister’s precautions, barring the spray.

Dr. Campbell was not aware that his operations had resulted any better since he had adopted Listerism than before. Even cleanliness he regarded as overrated.

Dr. Sutton could not admit that the operators he had cited were in the habit of resorting to Listerism, all but the spray, for no specific germicide was used, but cleanliness only. Whatever good was to be attributed to the spray was, he believed, due to its wetting the germs, thus causing them to fall to the floor, rather than to its killing them; and no doubt pure water would accomplish the same purpose, whether in the form of spray, or delivered from a sprinkling-pot, or thrown on the floor with a broom.

Afternoon Session.

On recommendation of the Council, the following-named gentlemen were added to the number of invited guests: Dr. Samuel D. Gross, of Philadelphia; Dr. R. B. Maury, of Memphis, Tenn.; Dr. William E. Moseley and Dr. William P. Chunx, of Baltimore.

Hot Water in Secondary Hemorrhage after Pelvic Operations.—Dr. Albert H. Smith, in a paper with this title, spoke of the prominence that Dr. Emmet’s teaching had given to the use of hot water as a hemostatic, Dr. Emmet having, in turn, credited the late Dr. Pitcher, of Detroit, with originality in the matter. Ever since Dr. Emmet’s first publication on the subject, Dr. Smith had made use of the measure in a wide range of cases, and with the most satisfactory results. Indeed, it had become so much a matter of routine that he would not have thought of making it the subject of a paper but for the fact that he had reason to believe that in some quarters it was not yet appreciated. His attention had recently been directed to the fact by a lecture given by Dr. Skene, of Brooklyn (see this journal for July 14, 1888, p. 29), in which mention was made of cases of secondary hemorrhage, after operations, managed by manipulative interference which imperiled the full success of the operative procedures. Cases were related illustrating the efficiency of hot water under such circumstances.

Dr. Thaddeus A. Reamy, of Cincinnati, corroborated Dr. Smith’s views, and stated that for many years he had had hot water poured on the perineum during the operation for laceration, instead of using sponges.

Dr. James R. Chadwick, of Boston, and Dr. William Goodell, of Philadelphia, coincided in Dr. Smith’s views.

E. H. P. C. Wilson would emphasize the advantage of hot water in post-partum hemorrhage. He also mentioned a striking instance of its beneficial action in a case of profuse hemorrhage during vaginal oophorectomy.

Dr. Campbell preferred to depend on diluted tincture of iodine as a hemostatic, as recommended by the late Dr. Trask, but did not doubt the efficacy of hot water.

Dr. Matthew D. Mann, of Buffalo, had not found the use of hot water always successful. He had never had occasion to use it in secondary hemorrhage; but, in a case of primary hemorrhage during the removal of a cancerous cervix, hot water proved of no avail. In that case, vinegar also failed, likewise the actual cautery and a firm iron tampon, and death resulted very speedily. An artery had been divided.
Dr. Goodell thought nothing could be expected of hot water or any other hemostatic in such a case as Dr. Mann's, but, in cases of oozing, hot water had some advantages over other hemostatics, for it operated on tissues beyond those with which it came in contact. Hot vinegar had the advantages of hot water, and also of its own specific action.

Dr. Barkee called attention to the slow action of hot water in some cases where the prompt arrest of hemorrhage was absolutely demanded, and to the delay often met with in obtaining it.

Dr. Byford concurred in the views expressed by Dr. Smith. Dr. Smith was gratified at the preponderance of opinion of the satisfactory action of hot water. In cases where death was impending, he thought it essential to elevate the hips, so as to carry more blood to the brain, and thus give the syphilitic an opportunity to act. No therapeutic measure would invariably operate to our satisfaction. He thought hot water and a Davidson's syringe were reasonably apt to be at hand under the circumstances to which his paper referred.

SOME POINTS CONNECTED WITH THE SUBJECT OF DYSMENORRHEA was the title of a paper by Dr. C. D. Palmer, of Cincinnati, in which the mechanical theory was characterized as plausible and natural, and was stated to have received a great impetus from the writings of Sir J. Y. Simpson and Dr. Marion Sims. The theory had continued to be questioned, however, and, although generally still accepted, and, although doubtless applicable in a certain number of cases, it was questionable if it could count for much in the general atiology of dysmenorrhea. The plausibility of the theory was strengthened by the temporary benefit so commonly produced by dilatation and other operative procedures calculated to relieve stenosis. There were several reasons why, the speaker thought, the theory should not be held to cover the general run of cases—chiefly included in the proposition that the pain was not proportionate in intensity to the amount of obstruction present, and that the most intense pain was often present without any obstruction whatever, while in cases of marked narrowing or sharp flexure of the uterine canal there was frequently not the slightest pain. On the whole, the obstruction theory could not be regarded as established. In many cases there was a state of the endometrium that might be called neuralgic—a condition that made it exceedingly sensitive on the passage of a sound, and that was aggravated by the congestion incident to menstruation, also by the contact of clots, etc. In a flexed uterus, hampered by the mere fact of the deformity, the tissue of the organ could not yield and swell during the menstrual congestion as it ought to do, so that the pain was the result of compression. In general, the affection was a neuritis, due to defects of the system at large, which latter might be an error of nutrition or an altered action of the nervous system.

In regard to treatment, in young women local measures should be omitted, at least at first. It was improper to regard every case of dysmenorrhea as calling for such treatment. To correct derangements of the system was our first duty. Local treatment might prove to be needed in the end. Iron would do much good in cases of scanty flow, and arsenic where the flow was profuse or too frequent. Electricity was uncertain in its effects. Sometimes corrosive sublimate and iodide of potassium, in small doses, continued for months, the author had often found useful. The same was true of moderate doses of tincture of rancifuga racemosa and tincture of pulsatillas during the periods. Opiates were to be given only with the greatest caution, and only where absolutely required. Dilatation of the uterine canal should not be resorted to until medication had failed; and this measure did not really operate by dilatation, but partly by blunting the sensibility, and partly by rupturing circular muscular fibers. It was best done with graduated bougies, or with two-bladed dilators. Incision of the cervix, the author thought, had been much overrated, and resorted to far too often. Its field had now, with the lapse of time, been considerably limited.

Dr. Chadwick was very much of Dr. Palmer's way of thinking on the subject, and for some years past he had been gradually giving up the operation of incision, now limiting the latter to cases of marked stenosis of the os externum. The pain of dysmenorrhea, in obstructive cases, was, he thought, generally due to spasmodic contraction of the uterus or of the Fallopian tubes, analogous to the rectal and vesical tenesmus caused by fissure of the anus or prostatic obstruction, and reflex in its mechanism. He had treated several patients satisfactorily by inducing slight brosis before the flow and by giving coca and carbonate of ammonium during the flow.

Dr. Barkee thought Dr. Palmer had expressed, better than he had been expressed before, views with which in the main he was thoroughly in accord. Mechanical obstruction, he believed, was but rarely the real cause of dysmenorrhea, but he supposed it was sometimes. It was very important to distinguish between uterine and ovarian dysmenorrhea. In cases where the pain lasted only up to the beginning of the flow, he believed the pain was due to the effort of the uterus to relieve its own congestion by the occurrence of hemorrhage. This form of the disease was met with both in plethoric and in anemic women. Of ferocious preparations, he preferred the lactate, from its being the most readily assimilable—three to five grains three times a day, with chlorate of potassium. Where the uterus was really at fault, he had had more satisfaction from the use of apol than from that of any other remedy—two or three capsules, after each meal, beginning two days before the flow.

In cases where the pain did not begin until the flow had continued two or three days, there was excess of ovarian excitement. In such cases the bromides were very efficient, especially the bromide of sodium, ten to fifteen grains three times a day (at the middle of the forenoon, the middle of the afternoon, and bedtime), beginning several days before the flow.

SECOND DAY—MORNING SESSION.

The meeting was called to order at 10.20 a. m. by the President, who proceeded to deliver the annual address.

In addition to the Fellows present at the first day's session, the following-named gentlemen were in attendance: Dr. W. H. Baker, of Boston; Dr. Samuel C. Busby, of Washington; Dr. Charles Carroll Lee and Dr. Henry J. Garrigue, of New York.

THE PRESIDENT'S ADDRESS; A BIOGRAPHICAL SKETCH OF DR. NATHAN SMITH, FOUNDER OF THE DARTMOUTH MEDICAL COLLEGE.—The address alluded to the early history of ovariotomy. Dr. Nathan Smith having been the second to perform the operation, doing it independently of any knowledge of what had been done by Dr. Ehrhart McDowell. The President then traced the early career of Dr. Nathan Smith, followed by a story of his arduous work as a teacher of medicine and of his remarkable achievements as an organizer of medical colleges. The address closed with the prediction that a monument would yet be set up in New Hampshire recounting the deeds of Dr. Nathan Smith.

Dr. Samuel D. Gross, of Philadelphia, present by invitation, was not aware that Dr. Smith had not known of Dr. McDowell's ovariotomy at the time of his first operation. He added that Dr. Nathan Smith's greatest achievement had not been spoken of—that of begetting such a son as Dr. Nathan R. Smith, of Baltimore.

A RARE FORM OF ABDOMINAL TUMOR—THREE CASES.—Dr.
THADDEUS A. REAMY, of Cincinnati, read a paper recounting three cases of hematomas of the abdomen, and showed a specimen from one of the cases. In one of the cases there was a sarcomatous growth. In the two other cases puncture was followed by recovery.

Dr. Charles Carroll Lee, of New York, concurred with Dr. Reamy as to the extreme rarity of cysts of the omentum.

Dr. Sutro thought that as a rule a sarcoma of the omentum could not be distinguished from a carcinoma of the same structure, except by opening the abdomen, although perhaps by the method of exclusion the situation of a growth might be ascertained with reasonable probability to be in the omentum. Given a fluctuating tumor thought to be located in the omentum, he regarded it as dangerous to puncture it with a trocar or with an aspirator needle. In all such cases exploratory laparotomy should be performed.

Dr. Campbell thought that tapping sometimes had to be done in such cases as a palliative measure, under circumstances where laparotomy was not to be thought of.

Dr. Reamy argued in support of the practice of puncturing cysts under such circumstances, considering it free from certain dangers attaching to a like method of dealing with ovarian cysts; and, in fact, the two patients he had tapped had both recovered.

A paper, by Dr. Edward W. Jeske, of Chicago, on "A New Method of Operating for Fistula in Ano" was read by title, the author being absent.

CONGENITAL FISTULA OF THE FEMALE URETHRA WITH EXTRUSION OF THE BLADDER.—Dr. Campbell read a paper embodying an account of a case of this sort, in which, he thought, a plastic operation would be advisable at the time of puberty, the patient being now a young child.

Dr. B. B. Brown, of Baltimore, related a case somewhat similar.

Dr. Mann related a case of laceration of the perineum in a young child, in which he advised the operation at the time. It was done without difficulty, and the result was perfect. Arguing by analogy, he thought the operation had better be done early, so as to favor a more natural growth of the parts.

Dr. Campbell thought that, in such a case as he had related, the scarcity of tissue was so great as to interfere with the performance of a plastic operation.

A STUDY OF THE ETIOLOGY OF PERINEAL LACERATION, WITH A NEW METHOD FOR ITS PROPER REPAIR.—Dr. Thomas Addis Emmet, of New York, read a paper with this title, a notable feature of which was an expression of the author's belief that in ordinary cases of laceration of the perineum no symptoms were produced by the injury, after it had once healed, except those of a reflex nature. In many cases of complete rupture, the pelvic organs would still be found in their normal situation. Moreover, the ordinary forms of operation for closing perineal laceration rarely, if ever, overcome the symptoms for which they were undertaken. The explanation was, that it was not a solution of continuity affecting the muscular structure of the perineum that constituted the source of symptoms, nor the restoration of that structure that would accomplish the cure of such symptoms; it was the concomitant injury of the fascial structures of the pelvis that was of consequence, and it was to the repair of those tissues that our attention should be directed. Frequently the pelvic fascia was overstretched in difficult labor, especially if the perineum was "supported." In the operation for restoring the perineum, it was useless to carry the denudation so far externally as was often done. It should be limited to the true osium vaginae, and the perineum should be further strengthened by bringing forward a transverse fold of the posterior wall of the vagina, even if there was no proctocele. The mistake should be avoided, however, of taking up too much of the posterior wall, for that would give rise to an amount of tension that would make it necessary to remove the sutures to prevent their cutting out. The author had used perforated shot with sutures of silk-worm gut, and had been pleased with the efficiency of this device. During the past year all his operations had been done by the method described. [Here, by request, Dr. Emmet drew diagrams on the blackboard illustrating his operation, and the consideration of his paper took the form of questions and answers tending to explain the steps in the operation and their purpose. The features of the operation were, in brief, as follows: Two transverse crescentic spaces were to be denuded—an outer crescent with the concavity looking backward, and an inner crescent with the concavity looking forward. To establish the situation of these crescents, three tenacula were to be employed. With two of these instruments the open mouth of the vagina was to be brought together by inserting the points at the level of the upper limit of the remains of the hymen, one on each side. The points thus seized would mark the extremities of the anterior crescent, and while they were held together with the instruments the third tenaculum was to be inserted in the posterior vaginal wall, in the median line, at a point that could be drawn forward to meet the two former without giving rise to undue tension. This point would mark the center of the posterior crescent. The denudation having been effected, the two crescentic denuded patches were to be stitched together. This would have the effect of drawing the perineal tissues upward, so that the vertical rent in the median line would be much shortened, and could now be closed with a few sutures. The latter step, however, was not essential.]

Afternoon Session.

CONTINUATION OF THE DISCUSSION ON DR. EMMET'S PAPER.—Dr. Emmet gave a brief résumé of the paper, emphasizing his disbelief in the doctrine of a substantial perineal body as a supporting body. His operation was a simplification, enabling operators to effect repair who might be incapable of doing so by the ordinary operations.

Dr. Reamy could not avoid the conclusion that the operation could not well be substituted in general for the operation Dr. Emmet had previously incutulated. He doubted if there would ever be such shrinkage of the undenuded area between the two crescents as to do away with the danger of rupture occurring again at a subsequent confinement; and he doubted if the operation could do more than get rid of redundant tissue in the posterior vaginal wall.

Dr. Frank P. Foster, of New York, expressed himself as even more radical in the view that the perineum had physiologically no such office to perform as to sustain the parts above it, and therefore its restoration was not demanded as a means of support. In abnormal conditions of the parts situated above it, it might and often did supplement their defects. Moreover, it had certain functions, not pertinent to this discussion, which called for its repair.

Dr. Sutro dissented from Dr. Emmet's view as to the non-necessity of repairing lacerations of the perineum apart from injury to other structures, and appealed to common observation of the ills with which women with rupture of the perineum suffered, and which were commonly cured by closing the laceration. He traced a similarity between Dr. Emmet's new operation and the one practiced by Leggar.

Dr. Emmet again denied the supporting office of the so-called perineal body. He thought his paper had not been very clearly understood. In reality, he was not much at variance with the other speakers, as would be seen when the paper was read carefully.
The Management of Accidental Puncture and other Injuries of the Gravid Uterus as a Complication of Laparotomy.—Dr. Lee read a paper with this title, in which he expressed his belief that, in addition to the few cases on record, many more must have occurred. He then epitomized the scanty casualities of the subject—seven cases, including one, already reported, in his own practice. He dissented from Sir Spencer Wells’s advice to remove the uterus under such circumstances, and expressed his views in the following conclusions: 1. The pregnant womb may be punctured or otherwise wounded during laparotomy without necessarily causing abortion. 2. Miscarriage seems, both a priori and from clinical evidence, to depend upon injury of the uterine contents, not of the womb itself, however severe. 3. If the former has certainly occurred, Cesarean section is indicated, and should be performed promptly. In this case the utmost care must be taken subsequently to secure thorough drainage from the uterine cavity. 4. If the uterine walls alone are injured, the wound is to be treated on general principles. If there is a deep puncture or incision, it must be sutured with the minutest care, with exact coaptation of the edges. For this purpose fine silk sutures, rendered antiseptic, are the best. If there is a nick or superficial puncture, it must not be ligated, for ligatures cut through uterine tissue quickly. If the wound is too small to require sutures, the bleeding points must be touched lightly with Pagetian’s cautery until ooze has ceased. Good surgery and the dictates of humanity alike demand that, under such circumstances, a chance of survival should be given the child as well as the mother.

Dr. H. P. C. Wilson had had some experience of the sort alluded to by Dr. Lee. In a case of pregnancy of four months duration he had performed ovariotomy, and found a firm pedicle attached to the uterus. On dividing it there was considerable ooze from the uterine tissue, which had been encroached upon slightly by the scissors. It was checked with Monsel’s solution, and the patient did well, but, three or four weeks afterward, intense pains set in and lasted for about ten days, when an abscess broke and abortion took place. He did not doubt that the abortion was due to the abscess.

Dr. Henry J. Garrison, of New York, had had the good fortune to witness Dr. Lee’s operation, and it had been his impression at the time that the trocar did not open the amniotic sac.

Dr. William H. Byford, of Chicago, thought the profession indebted to Dr. Lee for the paper he had read. He called attention to the fact that it was only in Dr. Lee’s own case that pregnancy was suspected beforehand. He himself had had a case, in which also he had failed to make out the existence of pregnancy by omitting to examine for it. He thought that Dr. Lee’s rule as to stitching up the wound where the ovum was not injured should not be made absolute, for in his case, one of advanced pregnancy, the tractile action of the muscular tissue converted the puncture at once into a gaping orifice, and in such a case sutures would not hold. He thought that under such circumstances, even if the ovum was not injured, the uterus should be emptied and the wound stitched up. In early pregnancy, however, he would follow Dr. Lee’s rule.

Dr. Lee would in general avoid the use of Monsel’s solution. He thought there was great force in the distinction brought forward by Dr. Byford.

Is Extirpation of the Cancerous Uterus a Justifiable Operation?—This was the title of a paper read by Dr. A. Reeves Jackson, of Chicago. Starting with the general postulate that the use of a remedial measure that usually failed to accomplish its object was not kept up by honest and humane men, especially when its employment involved manifest danger to life, and deducing, from a review of the history of hysterectomy for cancer, that this operation very commonly proved the direct cause of speedy death, and that in other cases it scarcely did more for the patient than to render her last days somewhat more comfortable than they would otherwise have been, Dr. Jackson reached the conclusion that the operation was unjustifiable, whether done by the vaginal or by the abdominal method. The operation was incapable of such improvement as to make it anything else than too difficult and dangerous to be countenanced. Even when it did not destroy life, it might sometimes, by being really a partial procedure, stimulate and hasten the extension of the disease. The paper closed with a telling indictment of so-called “brilliant” surgery—operations that killed being termed brilliant.

Dr. Van de Warker placed great reliance on the use of cauteries, instead of operative measures, and he employed a saturated solution of chloride of zinc. He showed specimens of large sloughs cast off after the action of the caustic.

Dr. Emmer coincided fully with the views expressed in the paper. His experience had been limited to one case, which terminated unfavorably. In that case he had operated against his own conviction, as the operation was one he had always opposed. [This case will be found reported, in the proceedings of the New York Obstetrical Society, in this journal.] If the operation was to be done at all, it should be done by the vaginal method.

Dr. William H. Baker, of Boston, could not believe that operative measures were wholly useless, for in a number of instances he had operated for the removal of portions of the uterus for cancer, with the result of prolonging life for years. He described and figured his own method of operating, being a combination of Sims’s and Schröder’s operations. Dissolving the cervix loose from its attachments up to the level of the os internum, a cone-shaped piece was then removed, the apex reaching nearly or quite to the fundus. He had done this operation in thirty cases, and without a single death. Extermination of the entire uterus, however, was advisable in extremely few cases, and those were mostly cases in which the disease began in the body of the organ, the cancer being of the glandular form, and both body and cervix were involved. He had never seen just such a case.

Dr. Palmer thought that the best that could be said for hysterectomy was that it might possibly be justifiable in a few instances, those, namely, of sarcomas starting in the body of the uterus.

Dr. Sutton had operated in five cases, in all by Simon’s method. He thought the abdominal method should never be adopted in cases in which it was possible to perform the vaginal operation.

Dr. Jackson was not surprised to hear of the good results that had followed less dangerous operations in Dr. Baker’s hands, and he doubted if either Dr. Baker or Dr. Sutton would ever meet with a case in which he would advise extirpation of the uterus.

Third Day—Morning Session.

Election of Officers.—The following officers were elected for the ensuing year: President, Albert H. Smith, M. D., of Philadelphia; Vice-Presidents, James R. Chadwick, M. D., of Boston; Samuel C. Burney, M. D., of Washington; Secretary, Frank P. Foster, M. D., of New York; Treasurer, Matthew D. Mann, M. D., of Buffalo; Other Members of the Council, T. Gaillard Thomas, M. D., Fordyce Barker, M. D., of New York; Thaddeus A. Reamy, M. D., of Cincinnati; R. Stanbury Sutton, M. D., of Pittsburgh; For Active Fellowship, R. B. Maury, M. D., of Memphis.

(To be concluded.)
OBSTETRICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held June 7, 1883, the President, R. A. Cleemann, M. D., in the chair.

Interstitial Pregnancy.—Dr. F. C. Sheppard exhibited the uterus and appendages removed post mortem, and read the following report:

Through the courtesy of Dr. George S. Hull, of Chambersburg, Pa., I am enabled to present this evening the post-mortem specimen of one of the rarer forms of extra-uterine pregnancy.

The history of the case is given in such a clear and complete form by Dr. Hull that I will read it in his own words. "(April 11, 1883.) A few days ago it fell to my lot as coroner to hold an inquest on a colored woman who had died suddenly. Vomiting followed by death, together with a history of family troubles, led her friends to suspect her husband of poisoning her.

"About 3 a.m., pains had set in in the left inginal region, accompanied by severe vomiting. I could not learn whether the pain preceded the vomiting, or vice versa. A physician was sent for; he did not go, but sent three quarter grain morphine powders. She took one every hour, seemed easier, and the vomiting ceased. At noon, becoming very weak, the doctor was again sent for, responded in person, and found the patient pulseless at the radial; he ascertained that she had been constipated for about a week, and made a diagnosis of obstruction of the bowels; he gave five compound cathartic pills, and ordered an emen. In an hour the patient was dead.

"Autopsy.—Peritonæum inflamed (recent—no pus), stomach empty, save the pills, which were liquefied, intestines normal. About two quarts of clotted blood were found in the abdominal cavity. The womb was ruptured, a small circular rent in the fundus about the left cornu.

"The uterus was removed and the rent enlarged; a fetus of about three months with membranes entire was found. The placenta seemed attached at the point of rupture.

"The pregnancy seemed to be interstitial, the tube being involved. The lower half or two thirds of the uterus was much hypertrophied and contained two or three teaspoonfuls of mucopus, which could be pressed out at the os uteri. There was no communication between the pus-cavity and the cavity containing the fetus. The uterus was not adherent to the other organs.

A sketch by Dr. Hull shows the uterus inclined to the right side, the fetal sac occupying very nearly the normal position of the fundus, and the point of rupture a little to the left of the line of the umbilicus.

"It occurred to my mind that the rupture was spontaneous, causing the vomiting and pain of the night; however, the woman had eaten of sucrerait for supper, and it might have caused the vomiting, and that in turn the rupture. The morphin aloyed the symptoms for a time, but the hemorrhage was slowly going on, and peritonitis setting in; the former protostating, death took place from loss of blood. She was th mother of one child, and I was, to all appearances, in good health up to the time of the accident.

An examination of this very interesting specimen shows an enlarged wound with a dilated cavity, the walls of which are hypertrophied to a thickness of seven eighths of an inch; lining this cavity is a structure which appears to be a true uterine decidua: the os is small, with an irregular stellate outline, and is perfectly patulous; the cervix is partially absorbed. The right ovary is small and flattened; the left of about normal size. At the point of entrance of the left Fallopian tube is a large intra-mural cavity, which contained the fetus; the outer wall of this cavity is exceedingly thinned, and presents ragged edges at the point where rupture took place; to the inner wall are attached some remnants of the placenta; no communication can be detected between the fetal cyst and the uterine cavity. The cyst is apparently of from three to four months, and is presented with the membranes unbroken.

To cases of this class the terms interstitial, tubo-uterine, utero-interstitial, and parietal have been applied. Dr. Parry, in his work on "Extra Uterine Pregnancy," classifies them under the head of "tubo-uterine, or those in which the germ is arrested in that portion of the tube which passes through the uterus." They are very rare. An analysis by Hecker (quoted by Parry) shows twenty-six cases out of two hundred and twenty-two, and Parry, in his analysis of five hundred cases of extra-uterine pregnancy, finds but thirty-one of the tubo-uterine variety, but two hundred and thirty of his cases are grouped under the general head of doubtful. Mr. Alban Doran ("Obstet. Trans.," vol. xxiv, 1882, p. 254) has been able to find but six specimens in all London, although he states that "we see a goodly array of the more frequent tubal form in almost every museum." I will not occupy your time this evening by referring to the question of pathology or of diagnosis, as both points cover the entire ground of extra-uterine pregnancy, and will be discussed in a future paper.

The proper treatment to adopt in these cases is, however, a point of great interest, and merits notice. A ruptured extra-uterine fetal cyst may cause death instantaneously, as in the case of the English actress mentioned by Dr. Chabazian ("Obstet. Trans.," 1882, p. 157). "She was taking an ice in the Bois de Boulogne, she fell down suddenly, and she was dead." Poisoning being suspected, an autopsy was performed. No trace of poison was detected, but the ruptured pouch of an extra-uterine formation showed the cause of death. In this case, of course, there was no time for surgical interference, but in many, as in the one reported this evening, an appreciable interval elapses between the first symptoms and the fatal issue. The diagnosis being made, what would be the proper course to pursue? Unquestionably, laparotomy. An exploratory incision would at once reveal the true condition of affairs, and the surgeon could either incise the cyst, turn out the contents, ligate the bleeding points, suture the edges to those of the abdominal wound, and establish drainage, or, if thought better, remove entire the uterus and its appendages. Either plan would offer a very fair prospect of recovery, while if left without surgical aid the patient would be doomed to inevitable death.

A number of points of interest present themselves in the study of this interesting case, but the limits of a paper of this character forbid us taking them up. I might merely call your attention to the large quantity of blood; Dr. Hull states, about two quarts exuded from a comparatively trifling rent. This fact has been repeatedly commented upon by other observers. Dr. Parry states that some of the most severe hemorrages occur when the orifices are very small, and cites a number of instances in which from several pounds to two, and half gallons of blood have been found in the abdominal cavity after rupture of extra-uterine cysts.

In conclusion, let me recall to your mind Dr. Hodge's case. His patient went to the eighth month, labor was brought on by libating the os uteri, and the child delivered by rupturing the septum between the uterine cavity and the fetal sac; the child was delivered by the natural passages. The child lived two hours, and the mother made a complete recovery.

Dr. F. B. Baer had examined the specimens, and felt a doubt of its having been of the usual form of uterine tubo-gestation. That form was the rarest, and was considered the least dangerous because it was not liable to rupture in consequence of having the muscular tissue of the uterine wall to strengthen it. In Dr. Hodge's case, the septum of uterine tissue between the uterine
The skin of the abdomen was smooth, tense, and glistening, and could not be pinched up over the tumor. It was quite tender to pressure. Short- waved fluctuation was distinct over the whole surface, percussion was dull, a slight tympanitic resonance could be determined in both inguinal regions. No part of the fetus could be distinguished by abdominal palpation. In fact, all the external signs were those of an ovarian tumor. They imagined they heard the heart-sounds, but so indistinctly as to be uncertain. She said she had felt the fetal movement for several days very slightly. Per vaginam the cervix was found dilated, the os open so as to admit two fingers to enter it. The vertex of a fetus was felt presenting, and, singularly, was but slightly movable.

Considering the rapid enlargement in a few days, the excessive discomfort of the woman, as well as the imperiled circulation and the extreme improbability of the woman or fetus surviving until the latter had reached a viable age, they concluded the best course was to induce premature labor, and, from the urgent need of relief, to cause it by rupturing the membranes. This he did, and on the evening of the same day a still-born fetus was extracted. The upper part of the abdomen still continued almost as large as before. Examination per vaginam revealed the membranes of a second child. The rupture of these was followed by a gush and discharge of an enormous quantity of water. The second fetus and the placenta were soon extracted. The latter was single with two cords. One cord appeared to have only a membranous attachment, but closer examination showed that it had been torn off from the base of the other cord. The quantity of liquor amnii was so great that it soaked through folded quilts, mattress, floor, and ceiling, and dripped upon the floor of the room below. The uterus contracted firmly and the patient was at once relieved. The children were both males, and well developed for the sixth month; the second child lived a few minutes.

The fixed position of a fetus in the os in these cases had been given by M'Clin tock as a sure indication of a pleural pregnancy, but Dr. Montgomery confessed that this did not occur to him at the time, though he was unable to account for the anomaly. The existence of a single placenta in twin pregnancies was said always to be accompanied by children of like sex; this theory was here confirmed as far as was possible by one case. As to the cause of the condition, authorities greatly differ. Gervis, in “St. Thomas's Hospital Reports,” brought the causes under three heads: 1. Cases due to inflammatory conditions of the amnion. 2. Cases where the decidual was found diseased and hypertrophied, but the amnion healthy. This would cause effusion into the amnion by transudation owing to disturbed circulation. In these cases the fetus suffered and might atrophy. 3. It might arise from some maternal blood dyscrasia of uncertain nature, but evidencing itself by the same condition recurring in successive pregnancies in the same patient. The peritoneal mem brana might be the cause, and came under this head. Simpson said disease of the placenta was likely to recur in the same individual. Savage asserted that an edematous condition of the placenta was present in all cases of hydran nios. M'Clin tock found a morbid condition of the placenta in every case. Mercier always attributed it to inflammation of the amnion. Others had ascribed it to obstruction of the fetal portal circulation, or in the cord, giving rise to transudation into the sac from the surface of the cord. Hydran nios greatly endangered the life of the fetus. Of forty-three cases collected by M'Clin tock, in which children were born where this condition existed, twenty were still-born, sixteen of those had ceased to live for some days or weeks before labor, eleven of those born living died in a few days. Of thirty-three cases, four mothers died, showing a high maternal mortality.
In this patient the success of the treatment was greater than expected. As the distension had been so rapid, they feared loss of power in the walls of the uterus, and a consequent long first stage and liability to hemorrage. It became an important question to decide whether they were justified in undertaking so promptly the induction of premature labor, but they felt that the probability of the death of the fetus and the danger to the mother certainly in this case justified the procedure.

The Effect of the Operation for the Restoration of the Lacerated Cervix Uteri on Fertility.—Dr. B. F. Bahr read a supplement to a former paper of his on this subject. [See the journal for July 14th, p. 48.] He there expressed the conviction, based upon his own experience, that sterility did not follow as a result of the operation, as had been asserted, but because the pathological conditions which almost constantly existed with the laceration were frequently not relieved, and this applied especially to the old cases. He there made this statement: “The longer the time which has elapsed between the occurrence of the injury and its repair (pregnancy being absent during this time), the greater and more permanent will be the changes in and about the uterus, which almost necessarily result in a continuance of the sterility after the cervix has been restored”; and he also said that, if five years or more had expired between the occurrence of the injury and its repair, sterility would be likely to remain. In support of this, he reported the cases of twenty-seven patients, of which number thirteen had been sterile from six to sixteen years. Of this number not one had become pregnant since the operation; but, of the eight in whom pregnancy had occurred within two to five previous to the operation, he reported four that had become pregnant, and he now added two more.

Case V.—Mrs. X., aged thirty-two years, mother of three children, youngest three years of age, complained of severe metrorrhagia every three weeks, and profuse leucorrhoea in the intervals, together with a dull, aching pain in the lumbar region and pelvis, and a sharp spasmodic pain in the bladder, which caused an almost constant desire to micturate. She had lost weight, was anemic and nervous, and had so many obscure aching and pains that the doctor took refuge in writing the words “general hyperesthesia from nervous exhaustion.” Physical examination showed the perineum to be lacerated to the external sphincter-ani muscle, but not through it. The cervix uteri was torn bilaterally to the vaginal attachment, but not much hypertrophied. The body of the uterus was only slightly enlarged, but its cavity was relaxed and granular. On January 30, 1881, after four weeks’ preparatory treatment, he operated on the cervix, and secured a good result. He was made anxious on the second day after the operation by a rise of the temperature to 102° F., which, however, subsided to the normal by the next day. This rise he ascribed to the use of the curette just before operating, which he now thought ought not to have been done. This was the only instance in which he had observed a perceptible increase of temperature after this operation. This patient objected so strongly to the use of the catheter that he allowed her to pass her urine spontaneously. Since union was perfect here, he allowed his next patient to do the same, with a like good result, and this had been his custom ever since. It was his purpose to restore the perineum, but she was so much benefited that she refused to permit it, and returned to her home in Michigan. A communication received a few weeks since informed him that she was spontaneously delivered at term six months ago.

Case VI.—Mrs. Y. had had three children at term and one miscarriage, the latter two years previous to February, 1878, at which time she first consulted him. She complained of a drag-ging pain in the back from the sacrum to the nape of the neck, with metrorrhagia and leucorrhoea. The neck and body of the uterus were hypertrophied, soft, and tender, and the former was badly torn on both sides; the mucous membrane was excised and abraded; the sound entered four inches. February 17, 1880, he operated for the lacerated cervix; union was immediate. In his case-book he had noted, October 25, 1881: “This patient has been in excellent health since the operation; whereas I had pursued the ordinary local treatment at intervals during the two years before it, with only temporary improvement.” She was now in the fifth month of gestation. This made seventy-five per cent. of pregnancies following the operation in the eight cases of this class.

A stated meeting was held September 6, 1883, the President, R. A. Cleemann, M.D., in the chair.

Face Presentation with Eclampsia.—Dr. William T. Taylor read the report of a case, as follows: “Face presentations are somewhat rare. Dr. Churchill said, some years ago, in recording the statistics found, that in British practice they occurred once in 292 cases, in French practice once in 275 cases, and in German practice once in 130 cases. In my own practice I have met with about one dozen, and, as the last one was combined with eclampsia, I will report it to the society.

“During utero-gestation my patient enjoyed very good health, having no headache, no swollen limbs nor blotted features, no vertigo nor dimness of vision. There was no deficiency of urine, and therefore I did not examine it for albumin. Her appetite was fair, her bowels were regular, and she took a moderate degree of exercise; so that I had no reason to expect any trouble when labor began. On May 14, 1883, I was summoned, at 6 a.m., to visit Mrs. C. Haley, aged twenty-three years, a primipara, who was in the first stage of labor, having had a show since midnight. On examination, I found the os very slightly dilated, with the pains ‘few and far between,’ and the face of the child presenting, with the chin toward the sacrum. The nurse informed me that the patient had not slept during the night, and was very nervous and irritable. Her skin was moist, her pulse was normal, and she had urinated frequently. I gave her a mixture containing hydrate of chloral, bromide of potassium, and lithium carbonate, and directed her to have light broth home to my breakfast, intending to return in a few hours. At eight o’clock the husband came to my office and told me that his wife ‘had had a fit, and could not keep the medicine down.’ I arrived at the house at 8.30 a.m., and sent immediately for some powdered hydrate of chloral and an injection apparatus. The patient had had two convulsions, which were ushered in by complainings of her head, her face being very red, and her head drawn to one side, with the features much distorted. The first convolution occurred when the nurse was about to give the first dose of the medicine. Directly after my arrival a third convulsion occurred, and lasted for a minute or more, her head being violently drawn to the right side, with jerking of her arms and legs. I dissolved one draught of the hydrate of chloral in about four ounces of water, and threw it into the rectum. The fit yielded immediately. As she was unconscious, I had an excellent opportunity of examining her. The os was dilated to the size of a quarter of a dollar, and soft, so that it yielded gradually to the pressure of my fingers, when I discovered the face presentation, with the chin toward the left sacro-iliac junction. I endeavored to push the chin toward the breast, so as to bring down the occiput in the second position of Baudeloque. This I found somewhat difficult; but, as the os dilated under the pressure of my fingers, I reached the occiput, and, after several attempts, succeeded in bringing it down to a favorable position—the one aforesaid. My patient by this time was becoming rest-
less and uncontrollable, and, fearing another convulsion, I again gave her an injection of chloral, which quieted her. Having placed her on her back, and brought her to the edge of the bed, her limbs being supported by the nurse and another woman, the forceps was easily applied, and the head brought down below the interior of the instrument when the head was pressed against the perineum, allowing nature to finish the delivery. The child, a boy, was still-born, the cord being pulseless. In fact, I was apprised of this while endeavoring to dilate the os with my fingers, for a significant tremor had passed through the body of the child, assuring me of its death. The placenta was removed quite easily.

"During all this time my patient was unconscious, and had no return of convulsion from the time I gave her the first injection of chloral. As her pulse was good and her respiration easy, I applied a binder, and, having placed her in a comfortable position, left her sleeping. On my return, at 5 p.m., she was restless and slightly feverish, but, after taking a few doses of chloral and valerian, she was quieted to sleep. On the next morning, May 15th, she was perfectly conscious; pulse 80, temperature 99°F., and respiration normal. She had urinated freely, and, with the exception of slight soreness over the abdomen, was very comfortable. She inquired for the babe, knowing from her condition that it had been born, but the preceding twenty-four hours were to her a perfect blank. From this time she had no further trouble, and soon recovered. This case certainly showed the beneficial effect of injections of hydrate of chloral in controlling puerperal convulsions when they are of a nervous form."

Dr. Albert H. Smith remarked that face presentations and puerperal convulsions presented a large field for discussion. Dr. Taylor was very fortunate to be able to bring down the occiput and keep it down until the forceps could be applied. In this operation a man needed three hands—one to hold the head while the others manipulated the instrument. The mechanism of a primary face presentation, as reported in this case, was difficult to understand. It might occur secondarily from obliquity of the uterus and a sudden free gush of waters, causing a sudden engagement of the head before flexion could be secured. In such cases it was very difficult to secure and maintain flexion until the forceps could be applied. In the majority of cases of face presentation, even with the chin posteriorly, nature was best able to terminate the case satisfactorily. It was to this class that the aphorism "meddlesome midwifery is bad" was most applicable. The natural forces worked slowly, and the neck of the child became accustomed to the extreme extension which it had to undergo, while it was very bad to bring a sudden strain on the vertebrea and other tissues of the neck by too rapid forcing of the chin into violent extension by means of the forceps or otherwise. The consequence of the hasty procedure was a still-born child. The only ground for interference was an alarming condition of the child's pulse. If the child's heart was beginning to fail, we must take the risk and give it the benefit of the chance. The child's head could not be born in a face presentation until the chin had engaged under the pubes. The old teaching was that the chin posterior could not be born; but he was very early undeceived on this point, one of his earliest cases having been of this character. He had sent for his preceptor to come and bring perforating instruments, but, while awaiting their arrival, nature proved equal to the task, rotation occurred spontaneously, and a living child was born.

Dr. B. F. Baer inquired if version by the feet would not be much preferable to waiting for nature to deliver in chin-posterior positions.

Dr. Smith did not mean that we should never interfere in a case of this kind, but that a large majority, if left to nature, would terminate spontaneously by anterior rotation of the chin, with safety to both mother and child. He would decidedly negative the proposition of version by the feet, because, the amniotic sac having been necessarily ruptured by previous efforts to bring down the vertex, the waters would have been completely evacuated, and the uterus would be in a condition of spasmodic contraction, so that an attempt to turn would involve great danger of rupture of the organ. The introduction of the hand always increased the risk of septic absorption—two terrible risks for the mother, while the child was exposed to all the dangers of head-last delivery. He would consider chin-posterior presentations natural labors, and would allow them to terminate spontaneously unless there was some complication demanding version.

Dr. J. G. Allen coincided with Dr. Smith in his conservative principles. The risks of version to the mother were great—too great to allow it to be performed for the sake of the child. The operation of version was not looked upon in so serious a light as it should be, under all circumstances. In some instances it might be very easy, and might terminate well, but in others, apparently similar in conditions, the results to the mothers were bad. He would not lose one mother to save ten children. He would never resort to version unless the labor was impossible under other measures. Even after it was skillfully performed the child was often still-born. The increased risk to the mother was followed by no corresponding gain in safety to the child.

Dr. R. P. Harris thought the ideas of Dr. Smith were the same as held by most eminent obstetricians, and agreed with their practice as expressed to him in private correspondence.

Dr. Baer was willing to be taught. The views expressed this evening did not harmonize with the teaching of even the present day in Philadelphia. He had been taught that version would be proper if the case was diagnosed early and the operation could be performed before the waters were evacuated, and it seemed to him that the rational thing under such circumstances would be to turn. It was entirely a new light to him to consider chin-posterior cases as easy, natural labors. He had been taught to look upon them as impossible of spontaneous completion, rotation never taking place, the forces in action not being great enough to compel it. His own recent experience had led him to doubt this dictum; with one blade of the forceps, used as a vestis, he had without difficulty secured anterior rotation. His idea of the impossibility of rotation under the circumstances had made him doubt the correctness of his diagnosis of the position, but the principles put forth this evening reassured him. Might the death of the child, causing relaxation, be the cause of the face presentation?

Dr. Allen did not expect others to accept his opinion, but in his denunciation of turning he alluded to the complete transposition of one extremity of the fetal ellipse for the other, and did not include the changing of one part of the head for another; but, in the first class, the poor chance of saving the child would not compensate for the increased danger to the mother.

Dr. Smith did not consider the chin-posterior an easy natural labor. On the contrary, it was the most difficult of natural labors. The chin struck upon the posterior inclined planes and was rotated to an anterior position, in which it engaged under the arch of the pubes exactly as the vertex would. In multipara, nature was able to accomplish this result, but in primipara assistance in rotation might be required, and even traction might become necessary. In contrasting the dangers incident to version by the feet and those involved in trusting to nature in this condition when the waters had been discharged, as they necessarily had, in the attempts to bring down the vertex, which would be first tried, we must remember that the child would be tightly grasped by the uterus, and that it must be twisted upon
MEDICAL SOCIETY OF THE COUNTY OF ERIE, N. Y.

A special meeting was held in Buffalo, September 8, 1882.

Dr. Storck in the chair.

Report of the Committee on Legislation, Embodied a Draft of "An Act to Establish the Medical Faculty of the University of the State of New York and to Regulate the Licensing of Practitioners of Physic and Surgery."—

The object of calling a special meeting of the society was then stated to be the hearing of the report of the Committee on Legislation, and the chairman called upon the secretary of that committee, Dr. Hopkins, to read that report.

Dr. Hopkins prefaced the reading of the bill by the following remarks:

"The University of the State of New York was intended by its founders to be the organic head of the educational system of the State. Its influence was to be exerted and its control exercised over the various institutions of learning by a direct supervision of their incorporation, and then by a continuous system of visitation and reports. The university was first incorporated in 1784, and its present authority is a law passed in 1787, which law is said to have been drawn by Alexander Hamilton, who was a member of the Assembly at that time. The control of the university is by its Board of Regents, which consists of four ex-officio and nineteen other members, chosen by the Legislature. The ex-officio members are the Governor, the Lieutenant-Governor, the Secretary of State, and the Superintendent of Public Instruction. The elected members must be citizens of the State, and must not be officers of any college or academy. The ninety-fifth report of the regents, for 1882, includes returns from thirty-six colleges, having an attendance of 9,928 students, and showing graduates for the year 1,644 in number. Besides this, the regents visit about 250 schools of academic grade and distribute to them a school fund of about $40,000 a year.

"The uniform and intelligent development of the educational interests of the State has not altogether followed the lines laid down by the framers of the constitution of our university, in that the legislature has from time to time granted charters to colleges upon terms less likely to secure the permanent efficiency of such institutions than would the terms imposed by the regents, the policy of the regents having been to discourage the establishment of feeble and ill-endowed institutions and to foster and encourage those with ample endowments. Although occasional legislative acts have been at variance with the educational policy of the university and of the State, the great mass of legislation is quite in harmony with, and, in fact, has been shaped by that policy.

"As a member of the Committee on Legislation of the Medical Society of Erie County, the writer was led to look with some little care into the history of medical education in our State, and, as a result of such study, is of the opinion that the faults of our present time are in great measure due to the neglect on the part of the proper authorities to develop and carry into effect the profoundly wise and statesmanlike ideas of Hamilton and his associates, shown in the formation of our State university. The bill which that committee is about to report to the county society is drawn with the view of attempting to turn the stream of medical education into the channel indicated by the early framers of our educational policy. This bill proposes the establishment of the Medical Faculty of the University of the State of New York, and further proposes to endow that faculty with the sole authority to grant licenses to practice physic and surgery in the State. In conversation with members of the committee, it was thought that it would not be without interest to the society to have a brief digest of this bill submitted for its consideration. This bill will probably be offered upon the authority and responsibility of our county society, and it is the hope of the committee that under such authority the co-operation of the medical profession of the State may be secured to urge its passage by the next legislature.

"As before remarked, the bill provides for one more step in carrying out the idea of a university, by providing for the medical faculty of such university, and will have the immediate result of separating the teaching and the licensing powers. Under its operation the faculties of the various medical colleges will teach, but that of the university only will license. Not only will the faculty of the university not teach, but no man will be eligible to a position upon that faculty who is connected with any teaching faculty. The divorce of the teaching and licensing powers is to be absolute and unconditional. This is in harmony with the plan of the university, which provides that no person officially connected with any college or academy shall be eligible to the position of regent.

"The bill provides that the Governor shall appoint this faculty, consisting of nine members, who shall be legally authorized practitioners of physic and surgery, and stipulates that none of them shall be connected with any medical school, and that, in such appointments, the several systems of medicine shall receive pro rata representation, and that no one can enter upon the practice of medicine in this State after November 1, 1884, without the license of this faculty. Appointments shall be made for three, four, and five years; after the first all shall be made for the long term. This faculty is made the highest medical body in the State, and is to have the oversight of all medical societies and institutions, and may be appealed to by all such societies upon any question at issue in the same concerning any subject upon which such society is authorized to make by-laws, and is expected to influence such societies that they may more efficiently carry out the object for which they were established. The proper officer may administer an oath, and the faculty may take testimony upon any matter coming within their powers. They shall meet at least twice a year, and examine candidates for licenses to practice medicine, and shall report in writing to the regents of the university all questions, answers, and opinions in each case. The examination shall be in anatomy, physiology, histology, pathology, theory and practice of medicine, chemistry, surgery, obstetrics, materia medica, therapeutics, and such other branches as they may consider proper. The questions in materia medica, therapeutics, practice of physic, and surgery or obstetrics, except the practical parts thereof, shall be proposed by an examiner in the same school to which the candidate wishes to be licensed; in all other respects the examinations shall be the same in each case. The records of the examinations and the findings of the faculty are to be a part of the public records of the university. Graduates of medical colleges in good standing with the faculty, who are over twenty-one years of age, and of good moral character, are eligible to examination on paying a fee of twenty-five dollars. At least six members must vote in favor of a candidate to give him a license, and then the regents of the university grant the license, for which the candidate pays the further sum of fifteen dollars. The faculty also have the power
to declare what shall be unprofessional conduct, and to withhold or revoke licenses for the same; such a vote must also be by a two-thirds majority. The faculty shall elect such officers and establish such rules as they may deem necessary, subject to the approval of the regents. The bill has no action upon persons now practicing under a legal registration, and provides that all persons wishing to commence the practice of medicine in this State must, besides getting the license of the medical faculty of the university, register in the county clerk's office the name, residence, place and date of birth, date of diploma, the institution granting the same, and the date of license to practice in this State; shall exhibit the diploma and license, and swear to the same; to swear falsely in registering will constitute perjury, and to practice under an illegal diploma, or without license, shall be a misdemeanor, rendering the person guilty thereof liable to a fine of two hundred and fifty to five hundred dollars for the first offense, and afterward to the same fine, and to imprisonment for not less than thirty, nor more than one hundred and eighty days. The bill defines the term 'practice of physic or surgery.' It changes itinerant vendors of drugs or nostrums a license fee of one hundred dollars a month, and exempts from its provisions the commissioned medical officers of the United States army, navy, and marine-hospital service, and the members of the house staff of any legally incorporated hospital.

"The bill is as follows:

An Act to establish the Medical Faculty of the University of the State of New York, and to regulate the Licensing of Practitioners of Physic and Surgery.

Section 1. On or before the first day of June, 1884, the Governor shall appoint the Medical Faculty of the University of the State of New York, to consist of nine members, who shall be legally authorized practitioners of physic and surgery in this State, but none of whom shall be connected with any medical school or college; provided, that in the appointments made the several systems of medical practice recognized by the incorporated State medical societies of this State shall receive pro rata representation, and all persons desiring to enter upon the practice of physic and surgery in this State after November 1, 1884, shall, before so doing, comply with the provisions hereinafter prescribed, and obtain the license hereinafter provided.

Section 2. Of the nine members of the said medical faculty, three shall serve in the first instance, for three years, three for four years, and three for five years, and these terms shall be severally distributed by lot at the first meeting of the said faculty. All appointments made in the faculty at the expiration of the several terms fixed above shall be made uniformly for the period of five years each.

All vacancies occurring in the said faculty from whatever cause shall be filled, before the next semi-annual meeting of the same, by the appointment, by the regents of the university, from persons nominated by the several State medical societies, of a practitioner of the system of practice that had previously been represented by the seat so vacated.

Section 3. The said medical faculty shall examine all applicants for license to practice physic and surgery in this State; they shall meet at least semi-annually; and at such meetings shall faithfully examine all candidates referred to them for that purpose by the chancellor of said university, and furnish him a detailed report in writing of all the questions and answers of each examination, together with a separate opinion of each examiner as to the qualifications and merits of the candidates in each case. The president or secretary of the faculty shall have authority to administer oaths, and the faculty to take testimony in all matters relating to its duties.

Section 4. Such examination shall be in anatomy, physiology, histology, pathology, theory and practice of medicine, chemistry, surgery, obstetrics, materia medica, and therapeutics, and such other branches in the several departments of medical science as the said faculty may agree upon, subject to the approval of the regents of the university.

The questions forming such examinations shall be the same for each class of candidates offering themselves, with the exception of the departments of materia medica, therapeutics, practice of physic and surgery, and obstetrics, except the operative practical parts thereof, in which branches the questions for each candidate shall be prepared by the representatives in the board of examiners of the system of practice to which such candidate wishes to be licensed.

Section 5. The said reports of the examination shall forever be a part of the public records of said university, and the orders of the chancellor, addressed to the medical faculty, together with the action of the regents in each case, shall accompany the same.

Section 6. Any person, on paying not less than twenty-five dollars into the treasury of the university, and on applying to the chancellor for the aforesaid examination, shall receive an order, addressed to the aforesaid medical faculty, instructing them to examine the candidates at one of the regular semi-annual examinations, provided that proof satisfactory to the chancellor is first given that the candidate is over twenty-one years of age, of good moral character, and has received a diploma issued to him or her and conferring on him or her the degree of doctor of medicine from some legally incorporated medical college held to be in good standing by the said medical faculty.

Section 7. The regents of the university, after finding that not less than two thirds of the members of said faculty have voted in favor of a candidate, and that such examination has been a satisfactory test of the qualifications of said candidate, shall issue to him or her a license to practice physic or surgery in the State of New York, for which license the candidate shall pay to the university the further sum of not less than fifteen dollars.

Said faculty may refuse to recommend a license to individuals guilty of unprofessional or dishonest conduct, and they may revoke licenses if, in their judgment, such actions do not merit the confidence of said university.

Section 9. The medical faculty shall establish such rules and regulations and elect such officers as they may deem necessary to insure the faithful execution of this act, subject to the approval of the regents of the university.

Section 10. Every person (excepting such as have heretofore lawfully registered pursuant to the laws of the State in force at the time) complying with sections 6 and 7 of this act shall, before commencing to practice physic or surgery, register in the clerk's office in the county where he or she practices or intends to practice physic or surgery, in a book kept by the said clerk, his or her name, residence and place and date of birth, together with the date of his or her diploma and by what institution granted, with his or her license to practice physic or surgery within this State; at the same time the person so registering shall exhibit both the license and the diploma herein required to the clerk, and subscribe and verify, by oath or affirmation, before a duly qualified to administer oaths under the laws of this State, an affidavit containing a plain statement of all the facts as aforesaid, including his or her age, and shall file said affidavit and copy of said diploma with said clerk; said county clerk to receive a fee of twenty-five cents for such registration, payable by the person so registering. Nothing in this section shall be so construed as to prohibit medical consultations in the different counties of the State between legally qualified and registered physicians of this and neighboring States.

Section 11. A person who shall willfully swear falsely to any statement contained in the affidavit required by the tenth section of this act shall be deemed guilty of and subject to conviction and punishment for perjury, and a person who violates any of the other provisions of this act, or who shall practice physic or surgery in this State under cover of a diploma unlawfully issued or illegally obtained or without a license as provided for in this act, shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by a fine of not less than two hundred and fifty dollars nor more than five hundred dollars for the first offense, and for each subsequent offense by a fine as aforesaid and by imprisonment for not less than thirty days and not more than six months. The fine, when collected, shall be paid one half
NEW YORK PATHOLOGICAL SOCIETY.

A stated meeting was held September 12, 1883, Dr. George F. Shrady, President, in the chair.

This being the first meeting of the season, the attendance was small, most of the members not yet having returned to town.

Obstruction of the Femoral Artery not preceded by Embolism.—Dr. Van Gieson said that at a former meeting of the society he had narrated a case in which thrombosis of the femoral artery occurred after pregnancy, not due, as he believed, to embolism. Since that time he had seen a very severe attack of phlegmasia dolens occurring in both limbs, with partial obstruction of the arteries, in which no signs of heart lesion could be discovered to indicate the possibility of embolism. He was inclined to the opinion, therefore, that there were cases of death of the intima preceding the formation of any considerable thrombosis in the artery, and independent of mechanical obstruction by an embolus. Whether or not the preceding condition should be called one of inflammation he was not prepared to say.

Dr. Amidor asked whether the contracted form of kidney was present.

Dr. Van Gieson replied that kidney disease had not been discovered in either case.

Dr. Amidor said he had asked the question because it was well known that not only in syphilis, but in chronic interstitial nephritis as well, a condition known as endarteritis obliterans sometimes occurred in the cerebral arteries, and he knew not why it might not also occur in the femoral arteries. He, however, had never seen the condition exist in the arteries of the limbs.

New Inventions, etc.

A NEW SPRAY APPARATUS.

By William C. Wilke, M.D., Sandy Hook, Conn.

Dr. Wilke, editor of the "New England Medical Monthly," writes us as follows:

I desire to call the attention of the readers of your valuable journal to a new spray apparatus which I have recently devised, and which, for completeness and beauty, is excelled by none that I am aware of. The great trouble with most spray machines is the great labor involved in filling the receiver. This is all done away with, and a few easy strokes of the lever soon fill the tank. A brief glance at the accompanying cut gives the reader a good idea of the mode of its construction. Its advantages over all the others are briefly enumerated below.

The air-receiver is three times larger than ordinary, the value of which is at once apparent to any one who has used the old style. It is tested to two hundred and seventy pounds to the square inch, and, as the gauge which is attached to it only records eighty pounds, it will at once be seen that it is an eminently safe instrument.
MISCELLANY.

The gauge is an accurate one, telling exactly the number of pounds pressure in the receiver at any time.

The valves are perfectly air-tight and very simple in their construction, and not at all likely to get out of order.

The pump, instead of being an ordinary affair held down to the door by the feet when pumping, and being very laborious to work at twenty pounds pressure, is attached to a bracket with an oscillating piston and lever, and can be pumped to a hundred pounds pressure to the square inch with the greatest ease. When the gauge indicates one pound pressure, every full stroke of the piston increases the pressure one pound, thus making it a very easy and quick manner of filling the receiver. The receiver is detached from the pump in a moment, and rests on a swinging shelf, with a stand to hold the phials and tubes when not in use. The phials are of special design, with thick necks to prevent their breaking in putting the corks containing the tubes in, an extra collar of glass being provided for that purpose.

The cut-off is very simple in its construction, and not at all liable to get out of order. It is always ready for use, perfectly air-tight, and responds to the lightest touch.

The spray-tubes are after the pattern of Sass, but, instead of being made of two tubes cemented or riveted together, which are extremely liable to break or spring and leak, are made of one solid piece of hard rubber, and the tips, instead of being permanently attached to the body of the tubes, are screwed in and are made interchangeable. By the means of a small wrench, which accompanies each instrument, they are readily unscrewed and taken out for purposes of cleansing, which is a great convenience. Any one who has attempted to clean an ordinary Sass tube when clogged will appreciate this point. Their great strength makes it almost impossible to break them by any ordinary usage. The metal parts are of the highest polish and nickel-plated; the wood is of black walnut, and so constructed as to be attached to a window casing or anywhere desired.

The lever is of ash, and is so made that by withdrawing a pin it becomes detached from the pump, the latter being held by a catch, the lever dropping out of the way. I was indebted during its construction to many valuable hints from Mr. John L. Saxe, of this place. Its low price, $75, brings it within the reach of all.

MISCELLANY.

THERAPEUTICAL NOTES.—Bromide of Potassium for Olycosuria.—At a recent meeting of the Paris Académie de Médecine ("Union médicale," Aug. 30, 1883), M. Dujardin-Beaumetz summarized a paper, written by M. Félixet, as follows: As an adjunct in the treatment of diabetes, bromide of potassium has its advantages and its inconveniences. In cases of moderate intensity, and in certain grave cases, it causes the glycosuria to disappear, if used in conjunction with dietetic measures and alkaline remedies, but it produces debility. We should, therefore, be very cautious in its administration, especially to diabetics already profoundly enfeebled by the disease itself, and it should be watched attentively. Sometimes its effect is striking, and it is applicable in all forms and varieties of diabetes. In the discussion, M. Boschart, M. Lunier, and M. Hardy agreed with M. Dujardin-Beaumetz as to the caution to be observed, but M. Ricord spoke more favorably of the drug, and thought the furunculosis commonly attributed to its use was really due to the disease.

Paraaldehyde and Aetal as Hypnotics.—At a recent meeting of the Berlin Society of Psychiatry and Nervous Diseases Dr. Langreuter ("Deutsche Medizinische Zeitchrift," Aug. 28, 1883) gave his experience with these drugs during a period of eight months at a lunatic asylum.

The paraaldehyde was employed in the form of the following mixture:

B. Paraaldehyde, 250 grammes;

Oil of peppermint, 5 drops;

Olive oil, enough to make 500 grammes.

The difficulty of dissolving the paraaldehyde and its burning taste were noted as drawbacks to its employment. The usual dose was 6 grammes; 2,500 grammes were used in all. Beyond a slight and transient irregularity of the pulse, no abnormal phenomena were observed; in quality, the pulse was always somewhat fuller. During sleep produced by the drug the breathing was deeper and slower; the pupils were not generally so much contracted as in physiological sleep, but dilatation was noted in but few instances. Sleep ensued in from five minutes to half an hour. In two cases the patients fell from the chair within a minute after taking the dose. The sense of sleepiness was readily interfered with, as the speaker had proved in his own person; quiet, therefore, favored the hypnotic effect, which took place after ninety per cent. of the evening doses, and after sixty-one per cent. of those given by day. In sixty-one per cent. a full night's sleep (seven or eight hours) was produced. A quieting influence was exerted even when sleep did not follow—most strikingly in excited paralytics and epileptics. In certain nervous affections, such as migraine, etc., the effect was favorable also.

The action of acetal was not so satisfactory, and only half as energetic, the medium dose required being from 8 to 10 grammes. Moreover, the taste and smell were found much more intense, and the effect was not so lasting. Nevertheless, excited patients became quieter, even if they did not fall asleep, contrary to what was observed after the use of chloral. In all, 2,700 grammes were used. Out of one hundred and sixty-seven trials, seventy-five per cent. were successful. Six grammes of paraaldehyde and 10 grammes of acetal were each
found equal to 2.5 grammes of chloral in activity. Although both the new drugs were weaker than chloral, they were to be preferred in certain cases in which the latter was contraindicated, as in cardiac affections. The speaker did not recommend sectal.

Croton-chloral in the Treatment of Whooping-Cough.—W. C. Webb, M. D., of Bryantsville, Kentucky ("American Practitioner," August, 1883), has come to the conclusion, from the treatment of nearly two hundred cases of whooping-cough, that croton-chloral is by far the most valuable single remedy for its relief. He has found that it is well borne by children. To affect the disease it must be given in decided doses. A child twelve months old will bear one grain of the medicine every four hours throughout the twenty-four. During the first week not less than this should be given. Thereafter, the cough is usually so much relieved that few if any doses are required at night. If the drug be thus pushed to its full effect, there are few cases that may not be entirely controlled in a fortnight. The dose for children ten years old should be two grains every four hours; adults will bear only about four-grain doses. The drug thus used does not derange digestion or affect the vital nervous centers. The first few doses may cause some irritation about the throat and faucets, but this soon ceases. The relief is so marked in some cases that patients fall asleep in their chairs.

Croton-chloral, if pulverized, will dissolve readily in compound tincture of cardamom. The following is a good prescription: B. Croton-chloral, 1/3; tinct. cardamom., 1/3; glycerin, 1/3. M. Sig. One half teaspoonful every four hours, for a child two years old and under. A less expensive and safer mixture is as follows: B. Croton-chloral, 1/3; tinct. belladonnae, 1/3; tinct. cardamom., 1/3; glycerin, 1/3. M. Sig. Dose, one half teaspoonful. If the paroxysms of cough are exceedingly severe, and if there is extreme gastric irritability, the croton-chloral should be preceded by a few whiffs of chloroform. The anæsthetic thus used produces the happiest effects, and it need not be repeated more than two or three times. The combination of bromides with the croton-chloral is of doubtful utility. If any of them are to be used, the bromide of quinine should be preferred. Watchfulness should, of course, be exercised during the use of croton-chloral, lest toxic symptoms should be manifested.

Carbon Monoxide and Pregnancy.—A debated point in animal physiology is the question whether carbon monoxide can pass from the maternal to the fetal circulation. The influence of the subject outside the sphere of pure physiology is small but important. Accidentally or suicidally, a pregnant woman may have succumbed from the respiration of fumes from burning charcoal. Can the life of a viable fetus be saved by the timely aid of a Cesarean operation? From his investigations on rabbits M. Hogyes has answered this question in the affirmative, since he was unable to detect the gas in the fetal circulation by means of a spectroscopic spectroscope. MM. Gréchant and Quinquaud, however, conclude (see "La France médicale," No. 16) that, in small quantities, carbon monoxide may pass over from the maternal to the fetal blood.—Lancet.

The LOCAL TREATMENT OF ACNE SIMPLEX and ROSACEA.—In a recent thesis, an abstract of which we find in the "Journal of Cutaneous and Venereal Diseases," M. Morin says that this can be satisfactorily carried out only by direct action upon the malady at its original seat. The following is the method devised and recommended by the author: He takes a fine darning-needle, having an eye somewhat longer than that of a sewing-needle. Holding this by the point, he introduces it into the affected gland by a rotary movement which causes some of the sebaceous matter to lodge within the eye of the instrument. The latter is withdrawn, cleansed, and re-introduced, and the operation is repeated once or twice until, the gland being emptied, its floor is touched by the needle, when a slight pricking sensation is experienced. The same needle, or another similar one, held in the same way, is then dipped in an alcoholic solution of iodine—of greater or less strength, but never weaker than that of the French pharmacopoeia—and is again passed into the gland, charged with a drop of the iodine tincture, which is thus brought into immediate contact with the focus of the disease. After a few minutes a clear liquid, slightly colored by the iodine, will exude from the gland, sometimes in a drop as large as a tear. This flow will cease within an hour. Twenty-four hours later, in cases of acne simplex, the inflammation, when unaccompanied by suppuration, will have wholly disappeared. If suppuration, however, had existed, it will be found perceptibly diminished, needing only two or three repetitions of the process to effect its entire cessation, followed by a permanent cure. Rosacea, being of a more intractable character, requires the application to be made several times, when results equally favorable will certainly be obtained. The advantages claimed for this mode of treatment over any local measures previously employed are: That it is easily carried out; produces no additional disfiguration; is painless; does not necessitate the exclusion of the patient, and may be relied upon to effect speedy cures even in cases otherwise hopeless.

THE MECHANICAL THEORY OF DYSMENORRHEA.—The "Lancet" closes an appreciative and just review of Herman and Vedeler's researches (already summarized in our columns) with the following remarks: "These figures show that the same proportion of women suffer from dysmenorrhea, be the uterus straight, slightly flexed, or acutely flexed. It appears, then, that, from whatever point these observations are taken, they lead to the same result—a result which entirely removes the ground from under the feet of the advocates of the mechanical theory of uterine pathology. These facts have been sought for, not in states of disease simply, but also in states of health, and, unless the accuracy of the observations can be impugned and the error pointed out, the pathology based upon the mechanical theory must be discarded and replaced by another more consonant with the anatomy and physiology of the organs concerned."

An AGED PHYSICIAN.—It is reported, says the "Lancet," that Dr. Jackimovics, of Jarovitsa, in the government of Kiew, Russia, has just died at the age of 106, and that he was able until near the close of his life to superintend the working of an extensive practice.

The AMERICAN Academy of Medicine will hold its next annual meeting in New York on Thursday and Friday, October 4th and 5th.

The ALBANY College of Pharmacy opens its new term October 1st.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from September 8, 1883, to September 15, 1883.—BARTHOLOM, John H., Captains and Assistant Surgeons, stationed from Fort Lapsi, Indian Territory, to Vancouver Barracks, Washington Territory. PAR. 2, S. 0. 128, Department of the Columbia, September 6, 1883. BATES, J. M., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Adams, Rhode Island. PAR. 3, S. 0. 170, Department of the East, September 10, 1883.

NAVAL INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending September 15, 1883.—Surgeon G. S. Beardsley and Passed Assistant Surgeon George C. Lippincott, detached from the Galena, and placed on waiting orders. Passed Assistant Surgeon H. T. Percy, detached from the Naval Hospital, Norfolk, and ordered to the United States steamer Galena. Surgeon George A. Bright, detached from the Naval Reynolds, Philadelphia, on September 30th, and ordered to the Galena, October 1st. Passed Assistant Surgeon H. A. Urquhart, ordered to the Alert on October 6th, and, on the arrival of that vessel at Yokohama, Japan, to be detached and to report for duty at the Naval Hospital at that place. Passed Assistant Surgeon M. H. Simons, to be detached from the Naval Hospital, Yokohama, Japan, on the reporting of his relief, and ordered to the United States steamer Alert.

SOCIETY MEETINGS FOR THE COMING WEEK.—Monday, September 27th: Medical Society of the County of New York. Tuesday, September 28th: Council of the New York Academy of Medicine; New York Dermatological Society (private); Medical Society of the County of Lewis, N. Y.; Jersey City Pathological Society (private). Wednesday, September 28th: New York Pathological Society; Auburn (N. Y.) City Medical Association. Thursday, September 29th: Section in Obstetrics of the New York Academy of Medicine; Brooklyn Pathological Society; Friday, September 29th: New York Clinical Society (private); Yorkville Medical Association (private); New York Society of German Physicians (private).
LECTURES ON

DISEASES OF THE KIDNEYS.
DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS.

By FRANCIS DELAFIELD, M.D.,
PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE.

LECTURE III.
The Symptoms of Bright's Disease in General; the Morbid Anatomy of Acute Parenchymatous Nephritis.

Gentlemen: I was describing to you yesterday some of the symptoms which are common to all the different varieties of Bright's disease of the kidneys, and I spoke to you, in the first place, of the signs that exist in the urine.

Another symptom which occurs in a good many cases of chronic Bright's disease, and in acute Bright's disease as well, though not in all, is dropsy. And by dropsy I mean the exudation of the serum of the blood through the walls of the blood-vessels, and the accumulation of it in the subcutaneous connective tissue and in the various serous cavities of the body. Such a dropsy is not by any means confined to Bright's disease. We may have it produced simply as a result of great anemia. The constant occupying of one position is capable of producing a certain amount of dropsy. Thus, if a person stands on his feet all day, and day after day for a long period of time, he may get up a dropsy of the feet and legs simply as a result of maintaining this one position. Then, again, anything causing an obstruction of the veins is capable of producing such an extravasation of serum into the connective tissues. In the case of renal diseases it is not always easy to tell the exact reason for the formation of dropsy. It is supposed by some to be due to changes that have taken place in the composition of the blood, and especially in the composition of the serum of the blood. Others think that it is due to the loss of albumin, which passes away in the urine, and so leaves the blood extremely thin and allows it to exude through the vessels. Others believe it is caused by certain changes in the walls of the blood-vessels, or in the force of the circulation and the pressure of the blood. Some of these various explanations will answer well enough for some of the cases of Bright's disease, but none of them for all. In those chronic cases where we do regularly have changes in the composition of the blood, and also changes in the circulation, and often, too, changes in the structure of the walls of the blood-vessels throughout the body—in those cases it is easy enough to understand the dropsy. But in some cases of acute Bright's disease we find it difficult to understand the reason for the production of dropsy. There are some of these cases in which the patient was previously completely well, and yet within a few days he becomes affected with general anasarca, and there is an accumulation of fluid in the different serous cavities. Here it is difficult to understand why the dropsy should come on so suddenly and be so extensive. The importance of understanding the causation of the dropsy is not a mere matter of theoretical importance, but it is a matter of real practical consequence, for, if we could understand the cause in each case, we should then know better what to do to get rid of it.

There are disturbances of the function of the stomach in a large number of cases of Bright's disease. Sometimes this manifests itself simply as a loss of appetite, or at other times in the development of symptoms of gastric dyspepsia, or in attacks of nausea and vomiting which may last for hours or days. In old cases of kidney disease there is apt to be produced a real lesion of the stomach in the shape of a chronic gastritis, and this adds its symptoms to those previously referable to the stomach. As to the intestines, the only symptom in these belonging to Bright's disease is a diarrhoea, which has the character of an ordinary loose faecal diarrhoea. This is especially apt to appear in patients who are dropsical, and who at the same time are passing only small quantities of water. But it may also be present in many cases of chronic Bright's disease without the existence of any great degree of dropsy, and with but slight diminution in the quantity of urine.

The lungs, too, are very apt to present some symptoms, and the most prominent one of these is dyspnoea, or a difficulty in breathing. The most characteristic form of dyspnoea with Bright's disease is that which occurs where there is no structural change in the lungs, no oedema, no accumulation of fluid in the pleural cavity, no disease of the heart, and no organic lesion to account for it. Here the dyspnoea seems to be purely nervous in character, and analogous to spasmodic asthma in its causation. It does not exactly resemble spasmodic asthma, but it does in the fact of its being apparently purely nervous in character, and in there being nothing as regards the mechanical condition of the lungs to prevent the patient from breathing as quietly and easily as any one. But the fact is that breathing is often a very difficult matter with these patients, and they are obliged to sit propped up in bed in order to catch their breath, and they may remain in this condition night and day for days or weeks in succession. In other cases the dyspnoea is really accompanied by an organic disease of the heart, or an accumulation of fluid in the pleural cavity, or by oedema of the lungs sufficient to account for it. But the nervous dyspnoea is that which is especially characteristic of Bright's disease, and particularly annoying to the patient.

In some cases, and especially in chronic cases of Bright's disease, we have changes referable to the eyes, and the patients lose their vision to a greater or less degree. These changes take place in three different ways: First, in some cases of Bright's disease the patients partly or almost completely lose the power of vision; and this may persist for hours or days, and then the sight returns; and yet, upon examination, we can find no structural changes at all, either in the retina or in the optic nerve. But more frequently we do find actual changes in the retina and optic nerve to account for the loss of vision. Sometimes there is simply a neuro-retinitis, an inflammation of that portion of the optic
nerve which is close to the eyeball, and of that part of the retina immediately around the optic nerve, and this is accompanied by a swelling of the optic disc and the retina, and an infiltration of them with serum. In other cases we find the retina the seat of an inflammation particularly characteristic of Bright's disease—a nephritic neuro-retinitis, as it is called. This is an inflammation of the optic disc and retina which involves a considerable portion of the retina, into which there is an infiltration of serum and an extravasation of blood; and there is also a degeneration of certain portions of the retina, altogether presenting a perfectly characteristic ophthalmic picture.

A moderate number of patients, and especially those with chronic Bright's disease, suffer more or less from neuralgic pains, referred most frequently to the face and head, but sometimes located in other parts of the body. These pains have the characteristics of an ordinary neuralgia; that is, they are short, sharp pains, shooting along the course of the nerves, lasting a few moments or perhaps several hours, and then suddenly disappearing, and apt to recur and be repeated over and over again at irregular intervals. These neuralgic pains are not so very common in Bright's disease, but they are a marked feature in some cases, and they may be so severe as to distract your attention from the real lesion from which the patient is suffering, and especially so if there is no dropsey present, and no other symptom except the changes in the urine to arouse your suspicions.

The blood also undergoes changes in its composition in all cases of Bright's disease which have existed for any length of time. But as to the exact nature of these changes we are very ignorant. We only know that the blood seems to be thinner and more watery than it should be, and it has not the same red color as is natural. In some patients there seems to be an excess of the serum of the blood, and in others there are extraneous substances found in the blood during life. But these changes are not found in all patients. What further changes there are in the composition of the blood we hardly know. But certainly they must be very important ones, for the blood is no longer able to nourish the body as it should. These changes in the blood therefore seem to be, perhaps, the most important results of Bright's disease.

We have in some patients with Bright's disease cerebral symptoms which may be only slightly developed or very strongly marked. Of these, headache is very commonly observed, either alone or else associated with a certain amount of apathy and dullness, or with the headache there may be associated an unnatural degree of restlessness and activity and inability to sleep. This sleeplessness occurs in a very large number of cases, and it is often a very distressing symptom, and one that it is difficult to relieve.

In some cases you may also have involuntary contractions of the voluntary muscles. These contractions may only involve certain groups of muscles, and especially those of the face, but in other cases all the voluntary muscles of the body are affected, and then we get general convulsions. These general convulsions are always a very marked feature of Bright's disease when they occur. You may have, either in acute or in chronic Bright's disease, a single convolution only, or such attacks may be repeated at intervals for days or weeks, or months in succession, or one after another may occur within a very short period of time. A patient may have five or six convulsions at intervals of only a few minutes between them, and in very bad cases they go on thus for twelve or twenty-four hours, it may be, succeeding each other very rapidly. In other cases the dullness and stupor appear first, and they become more and more marked until they have changed into a condition of complete unconsciousness, or they may even become so extreme as to resemble the coma of apoplexy. But you are more apt to have this unconsciousness followed by true convulsions. These cerebral symptoms, with the exception of the headache, are apt to occur in attacks. A patient may go on suffering from chronic Bright's disease for months or years, and during the largest part of the time have no cerebral symptoms at all, and then there will, perhaps, be suddenly an abundant development of cerebral symptoms, lasting, it may be, for hours or days, and then terminating in the death of the patient; or they may again disappear, and the patient will go on for another period of time perfectly free from cerebral symptoms. We have an exception to this rule in the case of headaches, which, while they may occur in attacks, we also may get as a continuous condition without any separate attacks. When a patient has one of these attacks of cerebral symptoms of which I have spoken, there are very apt to be at the same time attacks of the peculiar spasmodic nervous dyspnoea of Bright's disease, and repeated attacks of vomiting, and a diminution in the amount of urine. When a patient does have such an attack as this, he is usually said to have an attack of uremia. These are commonly called uremic attacks from their supposed origin, and they are always a very important feature when they occur in a case of Bright's disease. If a patient gets along without having any such uremic attacks, as he may, the course of the disease is apt to be a much more comfortable one. But when a disposition is shown to the development of such attacks, then the disease becomes a very distressing one, and calls for relief from the physician.

The prominent nature of these attacks of uremia and their severe character, and the fact that they often terminate in death, has always drawn a good deal of attention to them, and various efforts have been made to find out their cause; for, if we could determine this, then we could act intelligently in trying to prevent their occurrence or to relieve the attacks themselves. It is evident that these attacks have something to do with the functions of the brain, and we know that there is some disturbance in the functions of the brain, no matter if we are ignorant of the way in which it is produced. We know that there are changes in the brain which are capable of producing cerebral symptoms in other diseases where there are similar anatomical changes in the tissues and in the membranes of the brain, and we also know that changes in the composition of the blood are capable of irritating the brain in some way, and so may give rise to cerebral symptoms. These changes in the circulation may be either changes in the composition of the blood or changes in its quantity, or changes in the relative proportion of the venous and arterial blood entering into
the circulation of the brain. When we come to look into
the facts at our disposal as regards the causation of the
cerebral symptoms in diseases of the kidneys, we notice, in
the first place, that these cerebral symptoms are specially
common in connection with cases of chronic Bright's dis-
case, and markedly so in that form of the disease in which
the kidney becomes diminished in size, and in which there
is an actual disappearance of a certain amount of the kidney
tissue, and also marked changes in the tubules, the blood-
veins, and the stroma of the organ. We know, also, that a sim-
ple abolition of the function of the kidneys does not usually
produce a uremic attack; for when one or both ureters
suddenly become blocked up by the passage of large calculi
into them from the pelvis of the kidney, or when by an op-
eration an only kidney is extirpated, as has been the case,
or where injuries to the urethra have been followed by sup-
pression of urine—though in these cases the function of
the kidney is directly interfered with, and little or no urine
is passed—yet, as a rule, there are no cerebral symptoms
induced. We also know that some patients may have a
number of these uremic attacks. Patients with that form
of chronic Bright's disease especially in which there is the
atrophyed kidney may go on with no cerebral symptoms
for a number of years, and then perhaps during the course
of one or two years they may have several uremic attacks,
but yet in the months between the attacks they may have
no cerebral symptoms at all. So, from the consideration of
all these facts, it is evident that the condition of the kidneys
alone can not be the only cause of the production of these
uremic attacks.

Again, patients may have attacks of the very same char-
acter with very little change in the structure of the kidneys,
if any at all, as in cases of simple chronic congestion of the
kidneys, where there may be well-marked uremic attacks.
In the pregnant woman, also, either in connection with a
chronic congestion, or with no change in the kidneys at all,
there will sometimes be well-marked uremic attacks.

Some patients with chronic diseases of the arteries, or
in whom there is an habitual high tension of the blood,
may have these attacks when there is no disease of the kid-
eyes at all. So, you observe, the problem for us to solve is
a very complicated one indeed, for we have found, in the
first place, that the functions of the kidneys may be sus-
pended altogether without producing any uremic attacks;
and, in the second place, that there may occur uremic at-
tacks similar to those of Bright's disease in cases where
there is no change in the kidneys at all.

We also find, as we go on examining these patients with
chronic Bright's disease, that in some of them there really
occur actual changes in the membranes covering the brain.
It is quite common to find in them a certain amount of
thickening of the pia mater, which is evidently due to a
long-existing inflammatory process, and really there has
been a chronic meningitis which has taken on a very slow
and sluggish type, and caused a thickening of the mem-
branes of the brain.

In some cases, also, the brain is found to be very anemic;
or it may be oedematous and infiltrated with serum,
and the space between the ventricles of the brain and the
pia mater may be filled with serum. So in some cases we
really do have structural changes more or less extensive,
both in the brain and in its membranes. But these changes,
although they exist in some cases, do not in all; and, al-
though we may find them sometimes in patients who have
shown cerebral symptoms, yet we also find them where
there have been no cerebral symptoms; and, finally, we
may find cerebral symptoms have existed in cases where
there are no structural changes in the brain at all. Then,
when we come to the consideration of the blood, we find
that there are generally changes in the composition of the
blood, so that it contains more urea or other extraneous
substances than it should. It was the discovery of this
fact that led to the adoption of the name commonly given
to these attacks; that is, they were called uremic attacks
because it was supposed at one time that they were directly
due to blood-poisoning from the urea and other similar
waste products circulating in the blood. This belief in
the origin of the attacks is still maintained by many; but, if it
is the explanation of some cases, it is not true of all; for a
patient may pass no urine at all, and the blood may then be
loaded with urea and other excrementitious products, and
yet there will be no cerebral symptoms developed, while on
the other hand there may be cerebral symptoms in cases
where no urea or other excrementitious substances can be
found. So if this condition of the blood does cause uremic
attacks it is only one of the causes, and not the source of
all attacks.

Then as regards the quantity of blood which passes
through the brain. This may be altered by changes in the
cerebral arteries, either from disease of their walls, or from
a temporary spasmotic contraction of them, though of this
latter change we have no actual demonstration. We can
also suppose that changes in the arteries in other parts of
the body may easily have some influence in producing these
attacks, for a chronic inflammation of their coats, or a sud-
ren spasmotic contraction of them, may cause such a dis-
turbance in the whole arterial circulation as to be felt by
the brain. Or, again, we can well suppose that a too fore-
bile or a too feeble action of the heart may act as a cause of
these attacks by changing the amount of blood circulating
in the brain. Then there is another feature, an example of
which is seen in some cases, and especially in the uremia of
pregnancy, where there is an actual increase in the whole
amount of blood in the vascular system.

You observe, therefore, that I retain the old name, and
call these attacks uremic only as a matter of convenience,
and not because I believe that they are always, or even very
often, due to an accumulation of urea or other excrementi-
tious substances in the blood. But if we balance the prob-
abilities of all the various theories as to the causation of
these attacks, I think we shall reach the conclusion that they
seem to be due in general to two causes which usually act
together. These are: (1) a change in the composition of
the blood, and (2) a change in the condition of the circula-
tion of the blood through the vessels of the brain. When,
therefore, we have these two conditions associated, we
seem to have present the two features necessary for the pro-
duction of these uremic attacks. By changes in the com-
position of the blood I mean not only the accumulation of urea and similar substances in it, but also those other changes, the nature of which we are ignorant of, relating to the amount of water and various other substances in it. This view I have now given you of the nature of these uraemic attacks has a direct bearing on the proper treatment of them when they occur.

Now we will leave these general considerations and go on to a study of the actual diseases of the kidneys.

Acute Parenchymatous Nephritis.—In acute parenchymatous nephritis we have offered to us many different degrees of the inflammatory process. Some of these cases are very severe in character, and in some of them the inflammation is very mild, and therefore there is a difference both in the extent of the kidney lesion and in the variety of the symptoms in different cases. And, first, as regards the kidney lesions. The essential lesion in all cases is a change in the epithelium of the tubules and the epithelial cells lining the capsules of the Malpighian bodies. The blood-vessels of the kidneys, and the stroma, and the Malpighian bodies themselves, undergo no special changes; but the epithelium lining the tubules, and to a less extent that lining the capsules of the Malpighian bodies, does undergo very important changes.

In very mild examples of acute parenchymatous nephritis there is no great change observable in the size and the gross appearance of the kidney. Its size, weight, surface, color, and general appearance are essentially the same as in a normal kidney. But, on more minute examination with the microscope, we find that there are changes in the epithelium of the convoluted tubules of the cortical portion of the kidney; there is a certain amount of swelling and degeneration of this epithelium.

If you examine a case where the inflammation is more severe in character, you will find the gross appearance of the kidney changed. It is larger than normal, and this increase in size is due principally to a thickening of the cortex, which is seen to be swollen, and so the whole organ appears larger and heavier. Its surface still remains smooth, and there is no adhesion of its capsule and no congestion in its vessels. But, when you come to look at the cortex, you find that it is not only thicker than natural, but also whiter and paler; and this pallor contrasts with the red color of the pyramids, which retain their normal appearance. You will find the most marked changes to be those in the epithelium, and they involve the epithelium lining nearly all the tubes in the cortex and some of those in the pyramids, and the cells lining the capsules of the Malpighian bodies. You may also find some hyaline-cast matter in the tubes.

In still more severe cases, the changes in the gross appearance of the kidney are very great. The two kidneys may weigh a pound or more, and the cortical portion is very decidedly thickened and usually pale, or sometimes it has a mottled appearance, and a succulent-looking serum exudes from the cut surface. But sometimes there is no pallor of the cortex, but rather an actual congestion. Microscopical examination shows extensive changes in the epithelium of most of the tubules. It is swollen, granular, disintegrated, broken down in places, and separated from the walls of the tubules; and casts also are present in many of the tubules, mixed with broken-down epithelium and blood-globules, and in some of the tubes you may find blood collected in considerable quantities. These are all the changes that take place in acute parenchymatous nephritis, and in all cases they are essentially of the same character, but differ only in their intensity and amount.

Original Communications.

REPORT OF TWENTY-ONE CASES OF SUBCORACOID DISLOCATION OF THE HUMERUS REDUCED BY KOCHER'S METHOD.

By CHARLES A. JERSEY, M.D., LATE HOUSE SURGEON TO THE CHAMBERS STREET HOSPITAL.

Professor Kocher, of Bern, in 1870, published an article recommending a new method for reducing recent subcoracoid dislocation of the humerus;* and, in 1881, read a paper before the International Medical Congress, London, on the employment of the same method in luxations of long standing, stating in full the manipulation required, and giving a record of twelve cases, from three weeks to four months old, reduced by it; in one case, a patient seventy years of age, he was unsuccessful, fracturing the humerus; the case was of eight weeks' duration.†

Ceppi, in 1878, published an article on the reduction of subcoracoid dislocations by Kocher's method,‡ and, in October, 1882, in the "Revue de chirurgie," a second article on its employment in cases of long standing, recommending it as a procedure by which the head of the humerus may be replaced by the employment of little force and without anaesthetics.

Garafi, in 1881, wrote of Kocher's method, and recommended a modification of it for the reduction of subcoracoid dislocations.¶

Mr. W. Chisholm, House Surgeon of the University College Hospital, reports six recent cases—five subcoracoid and one subglenoid—under the care of Mr. C. Heath, reduced by this method; two subcoracoid required the administration of chloroform before reduction was accomplished, and the subglenoid was reduced only after some difficulty.|| Let me here call attention to the fact that in only one of the subcoracoid luxations reported by Mr. Chisholm were all the movements recommended employed, replacement being accomplished during the third manoeuvre in the others.

This method is recommended by Professor Kocher for

|| "Lancet," April 14, 1888.
subcoracoid dislocations. Reduction, as directed by him, is accomplished as follows: Patient, sitting up; the forearm is flexed to a right angle with the arm, the elbow pressed firmly to the side of the chest; the arm rotated outward until firm resistance is met with; then, the arm still rotated, the elbow is carried forward and inward over the chest to near the median line; then the arm rotated inward. The last movement is one of restitution, and carries the hand to the shoulder opposite the one dislocated. These manipulations resolve themselves practically into two movements—outward rotation and flexion, as insisted upon by Professor Kocher.

The difficulty experienced in accomplishing reduction of the head of the humerus in subcoracoid dislocation is due principally to the resistance offered to its return by the edges of the rent in the capsular ligament made at the time of the displacement. Traction and the manipulations of the older methods only serve to make the edges of this rent more tense, thus pressing the neck of the humerus more closely against the anterior edge of the glenoid cavity, and grasping more firmly the displaced head. Again, the inferior or posterior part of the capsule and the muscles which pass over and strengthen it cover over a portion of the glenoid cavity, partially occluding it, and in this way offer a further obstacle to the return of the bone to its normal position.

It is claimed by Professor Kocher that, by the use of the movements recommended by him, the edges of the rent in the capsular ligament are relaxed, more particularly the superior or anterior one formed principally by the coraco-humeral fibers, the obstruction caused by the inferior or posterior one removed, the opening rendered more patent, and the head of the bone approximated to the glenoid cavity. He says: "If now the arm is rotated so that the forearm, bent to a right angle, looks directly outward, this tense band before mentioned, with the head of the humerus, is also turned outward, and thereby the inferior or posterior capsular wall is forcibly lifted away from the glenoid cavity, and the hole in the capsule rendered more patent. But the head of the humerus is still firmly pressed against the anterior edge of the glenoid cavity, because, by the motion just made (outward rotation), the upper part of the capsule, as well as its under part, is not in the least relaxed.

"It is only after flexing, and carrying forward the humerus in its position of outward rotation, that the upper part of the capsule is relaxed, and, in consequence of the tension of the under part, which still exists and prevents the head from gliding forward, that it (the head) is thrown backward into its cavity," etc.

This method of reduction was first suggested to me by Dr. William T. Bull, attending surgeon to the Chambers

* The elbow in this movement should be kept away from the chest, and not closely applied to it.

† Professor Kocher here refers to the superior or anterior edge of the rent in the capsular ligament, which he affirms is formed chiefly by the fibers of the coraco-humeral ligament.

‡ Its point of insertion to the shaft of the humerus forms a fixed point, as it were, around which the humeral head revolves, the lower part of the shaft being used as a lever.
ing carried forward and over the chest, a fact to which Mr. Chisholm calls attention; unfortunately, a complete record of the number of times that this occurred has not been kept.

In those cases where a repetition of the manœuvres was necessary it was found that when some traction was made on the humerus in a downward direction, after the elbow had been applied to the side of the chest, and sustained throughout the remaining movements, reduction was effected with little or no difficulty. This is a procedure which I should recommend in all cases.

In examining the records of the twenty-one dislocations immediately preceding those here enumerated, all of them recent subcoracoid luxations, reduced by other methods, I find that the employment of an anaesthetic was necessary in seven cases before reduction was accomplished. The advantages claimed for Kocher's method are as follows:

1. The control obtained over the humerus by the position of the forcarm.
2. The advantage obtained by the relaxation of the edges of the rent in the capsular ligament.
3. The absence of the necessity for the employment of an anaesthetic.
4. The absence of pain to the patient, and of discomfort to both surgeon and patient, as compared to other methods.

A CASE OF Puerperal Septicæmia.*

By GEORGE T. HARRISON, M. D.,
ASSISTANT SURGEON TO THE WOMAN’S HOSPITAL.

As the following case presents some features of interest, I venture to report it to the Obstetrical Society. On the 5th of last December I was requested by a man to visit his wife, who was in labor, as he informed me, and under the care of a midwife. The labor was a protracted one, and the husband at last became so much alarmed about his wife that he went in search of a physician, and was directed to me. Soon after my arrival at the bedside of the patient I ascertained that the uterine contractions, with the accessory forces, were inadequate to effect delivery within a reasonable time; and, as the woman was showing evident signs of exhaustion (though the child's head was resting upon the perineum), I gave chloroform and applied the forceps. Careful as I was in my attempt to save the perineum, I was by no means successful, but, on the contrary, found that I had caused a laceration extending through the external sphincter ani muscle. I immediately brought the divided surfaces together by carbolized silk sutures. Everything went on well until the third day after delivery, when the patient was seized with a severe chill, followed by high fever. In conformity with my instructions, the midwife had been using daily vaginal injections of hot water, to which carbolic acid was added; but as soon as the patient showed signs of septic infection, as the evidence of which I regarded the chill followed by fever, I determined to make use of intra-uterine injections. By the local treatment the temperature was brought down in a short time from 104° to 102° Fahr.; and by the fourth day after the chill it had become normal. For the intra-uterine injection I used carbolized hot water, the strength of the solution being 2½ per cent. On the eighth day after delivery the patient had a slight rise of fever, and I recommenced the use of the local treatment which I had just discontinued the day before. The injection was given at night. The patient summoned me to her bedside after I had retired, about 2 a.m., complaining of very distressing symptoms, which greatly alarmed her. She had dizziness, ringing in the ears, numbness of the limbs, great oppression about the region of the heart, and a tendency to nausea. I found no elevation of temperature, and the pulse not accelerated. As she had been feeling well when I used the uterine injection, and as these symptoms came on soon after I left her, I could not come to any other conclusion than that the alarming symptoms were caused by the absorption of carbolic acid. A confirmation of this hypothesis was obtained the day after by the character of, the urine passed, which was of a peculiar greenish-black hue. In its odor and appearance the urine was so different from any she had previously passed that the nurse preserved it for my inspection, and called my attention to its peculiarities. As on the subsequent day I had a similar experience, I discontinued the use of the carbolic acid, and substituted in its place the sulphite of sodium. On the ninth day after confinement (December 14th) the pulse was 120, and temperature 103° 5. Uterine douche continued. At 3 p.m., pulse 148, temperature 104° 6. At 12 a.m., the pulse was 160, and the temperature, per vaginam, 106°. As the patient now exhibited signs of peritonitis, bimanual palpation demonstrating the existence of a considerable exudation in Douglas's pouch, and as the uterine injections had had no effect in reducing the temperature, large doses, too, of quinine internally being equally inefficacious, the use of cold water naturally suggested itself to reduce the temperature. The brilliant results obtained by Dr. Thomas in reducing the temperature, where fever ensued after the performance of laparotomy, by applying cold water to the trunk, encouraged me to adopt his method so far as I could under the circumstances. The use of the general bath was excluded, from the fact that I had no one to whom I could intrust its administration. I was therefore forced to extemporize an arrangement with the limited means at my disposal. A sofa was brought alongside the bed, an India-rubber cloth placed over it, and, at a point corresponding to the trunk of the patient, it was gathered into a fold, so as to make a gutter to discharge the water into a pan placed below. The patient's lower extremities were carefully covered with blankets, as well as the upper part of the body. Several folds of muslin were laid upon the abdomen, and then, by means of a Davidson syringe, the whole abdominal surface was irrigated. The temperature of the water was brought down gradually, At 4 p.m. the pulse was 148, temperature, per vaginam, 106° 4.

December 15th.—At 9 a.m., temperature 105°; patient looking much better. At 3 p.m., temperature 103° 8. At 6 p.m., pulse 132, temperature 103°. At 9 p.m., temperature 102°, pulse 124.

December 16th.—At 9 a.m., temperature 101°. At 1 a.m., temperature 102°, pulse 124. At 6 p.m., temperature 101° 4,

* Read before the New York Obstetrical Society, May 1, 1883.
pH of 112. At 10 a.m., temperature, 100° F., pulse 611. Douche ordered every three hours. Previously it had been used every half-hour. As it was continued for fifteen minutes every time it was applied, in eighteen hours she was subjected to the action of the douche nine hours.

December 17th.—At 9 a.m., temperature 100°-8°. At 6 p.m., pulse 88, temperature 100°-4°. Catheterized twice during the day. Patient is the subject of delusions. In the evening, apathetic. Has suffered for several days and nights from insomnia. At 9 p.m., temperature 101°-4°.

December 24th.—The patient has not been able to pass urine for more than a week. Two bed-sores were discovered on the back over the sacrum. Patient voided urine during the night voluntarily.

December 26th.—Temperature 103°-8°. Patient complains of pains in each side and shoulders; limbs ache. At 9 p.m., pulse 120, temperature 104°. I was disposed to attribute the rise of temperature to the effects of malaria, and, therefore, large doses of quinine were administered. There was no evidence of inflammation of any internal organ—no pleurisy, pneumonia, or disease of the pelvic organs.

The next day the temperature had returned to a normal condition. The mind of the patient had gradually cleared up, and she recognized those around her, though a few days ago she insisted upon it that her husband was some one else.

January 1st.—Patient sitting up and rapidly convalescing. Psychical disturbance following purpura phlebitis I have observed several times.

THE USE OF WATER IN THE DIETARY OF YOUNG CHILDREN.

By CHARLES REMSEN, M.D.,
HOUSE PHYSICIAN TO THE NURSERY AND CHILD'S HOSPITAL.

During my service as intern at the Nursery and Child's Hospital this summer, one factor in the production of infant mortality during hot weather has impressed itself strongly upon my notice. I refer to the ignorance shown by most persons, especially in the lower ranks of society, in regard to the amount of water required by children, either nursing or artificially fed.

Because the natural food of young children is in a fluid form, the laity generally suppose that no further supply of water is necessary. In medical writings on this topic, also, too little stress is laid on the importance of giving minute instructions in regard to this point.

When we consider the difference in the amount of fluids taken by an adult during hot and cool weather, it can readily be understood how a supply of water amply sufficient to meet all the requirements of a child in winter may be totally inadequate in the dry heats of summer. No provision for an increased supply, however, of this necessary principle is made through the natural channels; but, if the call for it be not attended to, the most serious consequences will result.

The blood, having parted with much of its water to supply the increased evaporation from the surface of the body, will take up very quickly the fluid portion of any food introduced into the stomach, leaving the solids too thick to be easily digested; these then ferment and produce indigestion and colic, and, passing downward, diarrhoea, and hence a further drain upon the blood. As a consequence of the thickened state of the blood thus produced, the excretion of sweat is stopped and a condition of collapse and hyperpyrexia developed.

When we take into account the fact that there is a larger proportionate area from which evaporation takes place in children than in adults, and that there is a greater amount of activity displayed in all the vital processes in the former, it is evident that their nourishment should be not only relatively greater in amount, but also given at much shorter intervals. In warm, dry weather, babies will drink cool water every hour, or even at shorter intervals, if, as it should be, it is offered to them. When they are suffering from diarrhoea, the amount they will drink and the improvement produced by it are astonishing.

The earliest sign showing the amount of water in the system to be below the normal standard is a slightly depressed condition of the anterior fontanelle. This may be present in children who otherwise present the appearance of perfect health; yet any slight increase in temperature or deprivation of the breast for a few hours may give rise in them to a sudden hyperpyrexia. In nursing children, however, the attention is usually first aroused by fretfulness, a moderate rise of temperature and pulse, a hot, dry skin, and a constant desire to nurse. If a child in this state be given a free supply of water, and its nursing restricted in frequency, the symptoms will often disappear quickly and completely; but, if not, collapse will soon come on.

In this condition the temperature ranges from 105° to 106° F., or higher; the pulse is small and thready, and beats from 180 to 200 to the minute; the skin of the body feels painfully hot, while the extremities are cool; the features are pinched and sunken, the eyes are half closed, with the pupils contracted, the fontanelle is depressed, the hands are tightly shut, the respiration is hurried and irregular, and consciousness seems abolished. In the majority of cases vomiting and diarrhoea have been absent, or, at most, the patient has had one or two small sliny stools. A child in this state will swallow water offered to it with greediness and the expression of the utmost pleasure.

The treatment adopted at the Nursery for these emergencies consists in wrapping the patient in a wet sheet, applying cold to the head, and giving as much water by the mouth as the child will swallow.

The results of this simple method have been extremely satisfactory, the child becoming quiet, and even going to sleep, while all the threatening symptoms subsided with great rapidity.

The attention given to this point as a prophylactic measure among the inmates has been followed by a diminished rate of mortality, and a marked reduction in the number of gastric and intestinal complaints.

In conclusion, it may be said that if more care were directed toward giving children a proper amount of water,
and restricting their hours of nursing or feeding, the mor-
tality due to hot weather would decrease, and less would be
heard about the troubles of teething.

THE CEREBRAL CORTEX.

By AMBROSE L. RANNEY, M. D.

(Concluded from page 315.)

We are prepared now to take up the special types of
cortex which are met with; and to study the hints which
are thus afforded respecting the functions of various parts.
By the laws of analogy, we are led to infer that parts
which have a similarity of construction, and in which
the cell-elements are absolutely identical, probably have
a similarity of function. If, on the other hand, the func-
tion of certain regions has, by physiological experiment,
been clearly made out, we are led to study closely the mi-
nute structure of those special regions, with the hope of
finding other localities where identical formations exist.

The superficial layer of the cortex has been described
by Virchow as "the neuroglia"; by Kölliker as "connective
tissue"; by Deiters as "spongy tissue"; by Rokitansky as
"ependyma"; and by Wagner and Henle as "fused ganglion-cell substance." Similar tissue found in the olfactory
lobes and Ammon's horn has been named "gelatinous sub-
stance" by Clarke, and "molecular substance" by Kupffer.
Hence, we must be prepared to meet descriptions of this
layer under the above-mentioned headings. This stratum
varies perceptibly in thickness in different mammals, and,
as Meynert expresses it, seems to be overbalanced and
thrown in the shade by the deeper nerve-cell laden strata
in the nobler types of brains. We find it relatively thin in
the brain of man and the monkey, thicker in the dog and
cat, and thickest (of all the domestic animals) in the calf.
The cells found in this layer are chiefly star-shaped (Mey-
內r),* have very little protoplasm, and possess many finely
divided processes. These are probably non-nervous in func-
tion. A few nerve-cells are found, however, which are char-
acterized by an excess of protoplasm (Deiters) and forked
processes; and some nerve-fibers may be also detected in
this layer (Arndt) in the region of the surface, which inter-
lace in all directions. In the "gyrus uncinatus" this me-
dullary layer is developed to a high degree.

In the majority of the convolutions of the cerebrum the
cortex may be subdivided into five strata. The structural
differences in the four strata, underlying the one already
considered, consist in variations (1) in the relative density
distribution, and (2) in the form of the nerve-cells.

As regards the form, that of the pyramidal (the only one
recognized by Arndt, Luys, Stephany, and others) prevails
in the five-strata type of cortex. In the second stratum,
the cell elements are of small size and closely packed together;
in the third, they are of larger size, gradually increasing
both in size and distance from each other as you pass in-
ward from the more superficial portion (the type peculiarly
indicative of Ammon's horn); in the fourth, Meynert de-

* Deiters recognizes only free nuclei in this layer. They measure
about 10 μ in diameter, according to this observer.

FIG. 4.—A TRANSPARENT SECTION FROM A SECTIONS OF THE THIRD FRONTAL
CONVOLUTION OF THE HUMAN BRAIN. (Meynert.) Magnified 300 times.
1, layer of the small dispersed cortical elements; 2, layer of the small, closely
packed, pyramidal cortical elements; 3, layer of the large pyramidal cor-
tical elements (Ammon's horn formation); 4, layer of the closely packed
cortical elements (granule-like formation); 5, layer of the spindle-shaped
cortical elements (claustrum formation); m, medullary substance.

* The spindle-shaped cells are not bipolar. Processes can usually
be detected which spring from their sides as well as from their ex-
tremities.
Considerable variety occurs in different parts of the cerebral cortex in regard to the size and shape of the nerve-cells, and the relative thickness of the layers. It is especially worthy of notice that, in those regions of the cortex which have lately been shown to contain the motor centers, the deeper pyramidal cells have been found by Betz to be very large, and arranged in clusters or nests of four or five cells, which are more or less defined. These are often called the "giant cells." They bear a strong resemblance to the large motor cells found in the anterior horns of the gray matter of the spinal cord. Bevan Lewis and Clarke have paid special attention to the situation of these peculiar cells, and have arrived at the conclusion that they are chiefly found among the small cells of the fourth layer of the cortex. The same observers have applied the name "ganglionic cells" to these peculiar elements, which apparently have an intimate relation with the function of muscular movement, and have designated the layer of the cortex in which they are found as the "ganglionic layer."

In the neighborhood of the calcarine fissure large cells in the cortex are very scanty, their place being occupied by those of small size. In some parts of the cortex six layers may be discovered; this is due, as shown by Bevan Lewis, to an insertion of an additional layer of small cells between the third and fourth layers. The claustrum, hippocampus major, or cornu Ammonis, and the olfactory lobe present especially characteristic variations of the cortex from the more common five-strata type shown in the diagram; but time will not admit of a minute description of the peculiarities of each.* It may be stated, however, that the study of the cortical elements has afforded grounds for many attractive theorems regarding the functions of special regions of the brain, and has also confirmed an opinion (previously formed by research in embryology and comparative anatomy) that the olfactory lobes and tracts are component parts of the brain, and are not to be classed among the cranial nerves. Luys has contrasted the structure of the olfactory bulbs with that of the retina; and the same author draws a strong analogy between these two organs of special sense and abridged projection systems.

From what has already been stated in regard to the anatomical construction of the cortex of the cerebrum, it seems logical to assume that each zone may be thrown into a state of nervous activity independently of the others, since the structure of the cells differs in the various strata. On the other hand, the connecting processes of the cell elements which unite the superimposed strata would seem to indicate that the various zones of the cortex may be associated in their action under certain conditions, and that the effects of nervous vibrations within the cells are in some way modified, according to the nature of the intermediate cells brought into play. Nervous actions, like vibratory undulations, are probably transmitted within the cortical substance both horizontally, along some special stratum, and vertically from the superficial to the deeper cells, or vice versa.

It is worthy of notice that in the posterior horns of the gray matter of the spinal cord we find cells of small size which are analogous in many respects to those of the second layer of the cortex: while in the anterior horns large cells predominate as they do in the third stratum. Morphological analogy would seem to indicate identical function. Luys advances the theory that the sub-meningeal strata which are characterized by the presence of cells of small size are to be considered as the areas of diffusion of general and special sensations; and that the deeper strata, characterized by the presence of large cells, are the centers for the development and emission of motor impulses. There is certainly some ground for a theory that the cortex may be regarded, from a physiological standpoint, as an extensive instrument possessing a sensory-motor function; analogous, in many respects, to the gray matter of the spinal cord, but endowed with special attributes of a higher order (consciousness, volition, memory, etc.).

We are inevitably forced to the conclusion that the cerebral cortex must be regarded as the chief, if not the exclusive, seat of mental activity. The essential proofs of the psychical function are as follows:

1. In the animal series, the cerebrum seems to be developed in excess of other parts of the brain in proportion as the individuals of any class approach the standard of man in mental powers. We judge of this by its weight, and also by the number of convolutions, or gyri, since the latter serve to increase the amount of gray matter in proportion to the superficial area of the brain.

2. In cases where the cerebrum is extremely small from birth, or where it is diseased, there appears to be a corresponding diminution in the higher mental faculties, or idiocy exists.

3. Mental disturbance almost always follows injuries, compression, and diseases of the cerebrum—as evidenced by insensibility, somnolence, abnormal excitement, or some marked eccentricities of demeanor.

4. Experimental physiology has shown that a removal of the cerebral hemispheres in the bird (in which animal it is easily accomplished) produces a stupor resembling sleep, in which all voluntary movement ceases. Flourens has noticed that a removal of the cerebrum in thin slices tends toward a gradual loss of mental power. Animals so mutilated are capable, however, of movements of a reflex character when any of the organs of sense are subjected to stimulation; but they are so regular in the order of their occurrence that they may be predicted, thus proving that they are not the result of volition on the part of the bird itself. Foster, in his work on physiology, gives an interesting and concise account and summary of similar experi-

---

* The researches of Bevan Lewis and H. Clarke in reference to the minute structure of the cerebral cortex in man and animals were published in the "Proceedings of the Royal Society" in 1878. The former author has also contributed articles to the "Philosophical Transactions" for 1880 and 1882. Meyner's valuable article is to be found in Stricker's work on histology. The most remarkable deviations from the normal five-strata type of cortex are to be found in the incurved portion of the cerebral hemisphere in the region of the hippocampus major (cornu Ammonis), and in the olfactory lobe. Henle gives cuts showing excellent sections of both of these regions. The articles referred to above will furnish the reader with a complete description of the peculiarities of structure which are characteristic of each.
ments made upon other animals. As most observers, however, have arrived at about the same conclusions, it is unnecessary to enter into detail here as to the results of the experiments made by each.

Now, from what has been already stated in this and a previous article, we can construct a general scheme of the nervous system as follows:

1. The central gray matter of the spinal cord, which has no connection with the higher senses, but which is capable, in itself, of the simplest kinds of reflex acts, by means of the spinal nerves. These can be produced, at the will of the experimenter, in the beheaded frog, when an irritation of the skin by any acid, etc., is created; and Robin has satisfactorily performed the same experiment upon a beheaded criminal. We have reason to believe that the spinal cord can be slowly and often painfully taught to perform certain series of muscular movements (as in playing scales upon a musical instrument, for example), in a purely automatic way, without any intervention of the higher ganglia.

2. The basal ganglia, and possibly the cerebellum, which are of a higher order, in point of construction, than the spinal gray matter, since they are connected indirectly with all the nerves of the spinal cord, and, in addition, with those of the special senses. These are capable, in themselves, of executing more complex actions, besides those of a purely reflex type, in obedience to impressions received from the nerves of special sense, as well as from the spinal nerves. These ganglia are probably important agents in guiding muscular movements in response to visual impressions and those from the sense of hearing; and, in this way, they seem to have an important control over the maintenance of equilibrium (co-ordinated movement).

3. The cerebral cortex, a ganglion of the highest order, in which the mental activities are seated, in addition to the function of elaborating and storing of sensory impressions of all kinds, and transforming them, at the proper time, into appropriate motor impulses. Here we encounter the mysterious realms where the living forces of our psychic activities are marshaled and organized, where volition has its seat, giving to the physical organization its individuality, and where those eternal problems respecting the relations of our corporeal and mental being are solved and carried into execution.

**Topography of the Cerebral Cortex.**—We are indebted to the admirable monograph of Ecker for a systematic grouping of the convolutions, or "gyri," which will materially assist us in studying the peculiarities of formation of each, and especially in defining special centers whose functions seem to have been determined by experimental physiology. The terms employed by this author and some of his predecessors are now embodied in most of the recent works on physiology and descriptive anatomy, although there are structural grounds (pointed out by Meynert) which make them appear somewhat illogical. We may simplify the study of this subject by first enumerating four lobes, four lobules, and "four sulci," or fissures, which are especially prominent upon the exterior surface of the cerebrum. These are as follows:

- **The four lobes are:**
  - The frontal lobe.
  - The parietal lobe.
  - The temporo-sphenoidal lobe.
  - The occipital lobe.

- **The four lobules are:**
  - The lobulus centralis (the island of Reil).
  - The lobulus paracentralis.
  - The lobulus cuneus.
  - The lobulus quadratus.

- **The four sulci are:**
  - Ascending limb of the fissure of Sylvius.
  - Horizontal limb of the fissure of Sylvius.
  - The fissure of Rolando.
  - The external parieto-occipital fissure.

The lobes are designated by the bones with which they bear relation; hence their names will serve to indicate their situation and extent. The main sulci, or fissures, are the dividing lines between the lobes; the smaller sulci seen in the diagram separate the different convolutions, or "gyri."

---

Upon the internal surface of the cerebrum, hidden from view by the contact of the hemispheres unless they be pulled apart, are three additional fissures, which have been designated as the "calloso-marginal," the "internal parieto-
occipital,” and the “calcarine.” These will be seen in the plate now indicated (see Fig. 8).

The frontal lobe (F in Fig. 8) is contained within the anterior fossa of the skull. It presents four “gyri,” which are specially named. These are as follows:

The ascending frontal convolution, or gyrus (A), which lies anterior to the fissure of Rolando, being separated from the ascending parietal convolution by that fissure.

The superior frontal convolution, or gyrus (F1), which joins the ascending gyrus, passing transversely across the frontal lobe.

The middle frontal convolution, or gyrus (F2), passing parallel to the superior.

The inferior frontal convolution, or gyrus (F3), lying below the middle, embracing the ascending limb of the fissure of Sylvius.

Benedikt has observed the frequent occurrence of a fourth frontal convolution in the brains of criminals. It was found to exist, more or less completely developed, in the majority of brains of this class to which he had obtained access. It originated usually by a bifurcation of the middle frontal convolution, occasionally by a bifurcation of the superior frontal convolution. Other points of interest are presented, including the occurrence of a fifth convolution. These facts the author regards as the expression of a great pathological law, that atypical structure is the chief agent in the production of atypical (morbid) performance of function.

The parietal lobe (P) has also four convolutions, or gyri, called the ascending, the supra-marginal, the parietal lobule, and the angular gyrus.

The ascending parietal convolution (B) lies back of the fissure of Rolando, being separated from the ascending frontal convolution by means of that fissure.

The supra-marginal convolution (P1), the parietal lobule (P2), and the angular gyrus (P3), being the other three convolutions of the parietal lobe, are situated behind the ascending parietal convolution.

The temporosphenoidal lobe (T) presents three well-marked convolutions, which run in an antero-posterior direction. They are named as follows:

The superior temporosphenoidal convolution (T1), which lies below the horizontal limb of the Sylvian fissure, and which is continuous behind with the parietal lobe.

The middle temporosphenoidal convolution (T2), which becomes continuous with the angular gyrus, and is connected to the middle occipital convolution.

The inferior temporosphenoidal convolution (T3), seen on the under surface of the cerebrum, and connected with the third occipital convolution.

The occipital lobe (O) presents three badly defined convolutions, which are superimposed upon each other, and which lie in a more or less antero-posterior direction.

The superior occipital convolution (O1) is connected with the parietal lobule.

The middle occipital convolution (O2) is connected with the angular gyrus, and also with the middle temporosphenoidal convolution.

The inferior occipital convolution (O3) is connected with the inferior temporosphenoidal convolution.

The admirable diagram (Fig. 6) to which I now call your attention shows the relative position of the gyri, as well as their extent, configuration, and lines of continuation into neighboring convolutions. While it is more schematic than that of Ferrier, it is better adapted for the purposes of instruction. In its general outline, however, it resembles the brain of the monkey, rather than of man, as the frontal lobes are small, and the fissure of Rolando somewhat far forward.

The lobules of the cerebrum demand individual men-

![Fig. 6.—A Diagrammatic Figure, showing the Cerebral Convolutions. (Deh strikes.)](image-url)
It is a triangular eminence, and consists of five or six straight convolutions (gyri operclei), which radiate outward from a point just external to the anterior perforated space. It covers the lenticular nucleus of the corpus striatum.* The drawing to which I now call attention shows the appearance of this lobule after the end of the temporo-sphenoidal lobe has been removed. The discovery of Broca that this lobule contains the center of speech (a statement which clinical experience has not yet been able to overthrow) has given it a clinical and physiological importance in excess of other convolutions.

The paracentral lobule (P in Fig. 8) is found on the internal surface of the cerebrum, in front of the lobulus cuneus. There is clinical evidence to sustain the belief that this lobule is, in some way, connected with the motor tract. We know also that disease of this convolution produces a secondary degeneration of nerve-fibers which can be traced through the cerebrum along the motor tract and into the motor regions of the spinal cord. The “giant cells” of Betz are also found in its cortical layer.

The lobulus quadratus (Q) lies between the paracentral lobule and the lobulus cuneus, as shown in this drawing (Fig. 8). It is bounded by the internal parieto-occipital and the calloso-marginal fissures.

The lobulus cuneus (C) lies posteriorly to the lobulus quadratus. Like the preceding lobule, it is inclosed between two fissures, the internal parieto-occipital and the calcarine.

Peduncular Fibers of the Cerebrum.—By means of the peduncular or radiating fibers of the cerebrum, the cortex is enabled to receive impressions of the external world and to transmit motor impulses to the muscles. The larger part of these fibers (as stated in a previous article) are capable of being traced into the crura and spinal cord, but it must be remembered that some also are intimately con-

---

* The applied anatomy of this ganglion has been presented in a late article by the author. See “Journal of Mental and Nervous Disease,” February, 1882.
a previous article (published in this journal, March 19, 1883), the course of these fibers was considered at some length, and a diagram was given to assist in mastering the more difficult points referred to; still it may not be considered a repetition to introduce at this time another diagram, which will make some additions to the facts already recorded.

Many points shown in this diagram are already familiar to you, but a few remain which deserve mention. One bundle, the "stria cornea," is shown in the drawing. These fibers run from the cortex of the temporal lobe of the cerebral to the caudate nucleus of the corpus striatum, and appear on the floor of the lateral ventricle as a curved band, the "talia semicircularis." The optic thalamicus receives fibers which spring from the frontal lobe, passing between the caudate and lenticular nuclei of the corpus striatum, and designated in the diagram as (a); also fibers from the temporal lobe, the walls of the fissure of Sylvius, the gyrus forniciatus, and the optic tracts. The so-called "geniculate bodies" are also shown to be connected with certain bundles of radiating fibers. The bundles which compose the "crusta" and "tegmentum cru ris" are made more apparent than in the diagram previously drawn. Finally, the fibers connecting the cortex of the cerebellum with the testis are clearly depicted.

(To be continued.)

Book Notices.

It is not very long since the Edinburgh edition of Hart and Barbour's work was noticed at some length in this journal. We can only repeat the favorable expressions we then made use of. In spite of the American prejudice against text-books in more than one volume, we think the reader will find the Messrs. Wood's edition a very pleasant form of the book, and we can not doubt that the subscribers to the series of which it forms a part will be pleased that it has been brought out in this form.

This is the essay which was published in serial form in the "American Journal of Obstetrics." It has evidently cost its author a good deal of pains, and we trust that its appearance in the shape of a book will secure for it a wider circle of readers than it would otherwise have had. Our own readers have been informed of the substance of Dr. Garrigue's views on the subject with which it deals, as set forth by him in the proceedings of the American Gynecological Society and the New York Obstetrical Society. An analysis of the work is therefore not called for at present.

BOOKS AND PAMPHLETS RECEIVED.

Annual Announcement of the Medical Department of Niagara University. Session of 1883-84.
Oliver Smith and William Tudor, Esq., were appointed a committee to report regulations for the institution. The expenses were to be defrayed by subscriptions, the first code of by-laws providing that each lady or gentleman who paid five dollars annually into the hands of the treasurer should be entitled to have the privilege of having two patients at one time under, the care of the dispensary; and the sum of fifty dollars entitled the donor to the privilege of having two patients in the dispensary during life. At the start, a centrally located apothecary’s shop was selected as headquarters, and here the patients came, orders were left, and the medicines given out. From the history of the dispensary we find that a “Mr. Bartlett, apothecary, was requested to procure a board, to be placed at the front of his shop, with the words The Boston Dispensary painted thereon, with such other device as may be congenial to the institution, and corresponding with his ideas and fancy.” The sign selected was “The Good Samaritan,” which since then has always been the symbol of the dispensary, and is prominent over the door of the new building. In the report for 1858 is the following: “Tradition says that the artist, in his anxiety to illustrate the full import of the scene described in Luke, x, 32, painted the Levite in the act of passing by on the other side. When the work was finished, the managers detected in the Levite so striking a likeness to a certain clergyman of the town that the figure was effaced.”

The first rules of the managers allowed any regular physician to draw orders for medicine upon the apothecary selected; but, after a while, the city was divided into districts, the size and number of the districts being changed according as the work increased; and with the growth of the city more apothecaries were selected, so that the work could be more easily accomplished.

In the early days applicants for aid had to obtain an order from a member or subscriber before the desired help could be furnished. When the central office was established, in 1858, this custom was done away with. In 1866 the managers allowed wine to be given to any patient who might absolutely need it. This custom was continued till 1818, at which time it was discontinued on account of a report made by Dr. John Ware, one of the physicians, who said that he had given out one hundred and thirty orders for a quart each, mostly to consumptives and old persons; for the rest, “not one quart was necessary for the recovery of patients,” and he recommended that the custom be discontinued. On February 26, 1891, the act of incorporation was obtained, the institution, through its managers, being allowed to hold real estate, provided that the interest from this and its personal property should not exceed five thousand dollars.

On January 20, 1852, an act was added enabling it to hold five thousand more, and on February 12, 1859, it was allowed to hold double the amount mentioned under the former act. In 1899, the expenses having greatly increased, and new subscribers not coming in in the same ratio as before, a committee was appointed to prepare and put in circulation a subscription paper in order to increase the funds. The yearly fund was in this manner increased one thousand nine hundred and ninety dollars, and the permanent fund four hundred and ten dollars; and, in addition, various sums were raised at different times by other means; and we find that, on February 21, 1821, Mr. Kenn appeared as King Lear at the Boston Theatre, for the benefit of the funds of the dispensary, five hundred and fifty dollars being realized; and later on, in 1823, three hundred and twenty dollars were raised from an exhibition of an Egyptian mummy. This curiosity is now in the possession of the Massachusetts General Hospital, and I believe was the first one ever brought to this country. Bathing facilities must have been few at that time, for on July 12, 1821, the managers voted that, “on applica-

tion of Dr. Chandler Robbins, Jr., a bathing-tub be purchased and deposited in some central place for the use of patients of the dispensary.” The work of the dispensary having so increased, and the need of such an institution having been demonstrated, and, in fact, recognized by numerous bequests, an appeal was made to the public, and, as a result of this appeal, the land where the present building stands was bought. There were two brick houses on it, and it was the intention of the managers to use one for a dispensary and one for a hospital, but both were used for the former—and it was here that the first permanent quarters of the dispensary were established. To quote from a circular issued at that time: “The estate is open on all sides to the light and air; it is almost the exact geographical center of the city; and seems to be in every way a most favorable situation for commencing operations under the new organization.” (The manner in which the organization was carried out was described in the journal for January 6, 1883, pp. 12 et seq.)

This, then, was the first home of the dispensary, and the words of that circular are as applicable to-day, for the new building is built upon the same site, and the institution will begin its eighty-eighth year with greater facilities and with new life.

The new building will be ready for occupancy about Octo-
ber 1st. It is situated on the site of the old building, at the corner of Ash and South Bennet Streets. The plan of the building is very nearly square, the dimensions being 65’ 8” x 65’ 4”, with an entrance porch and bay on Ash Street 6’ 0” x 24’ 6”. The building contains a basement, first and second stories, and a commodious attic in the roof. The only finished portion in the basement is a laboratory, 25’ 0” x 46’ 0”, fitted up with all the requisites for the compounding of medicines, the remaining space being devoted to a storeroom for the laboratory, fuel bins, and furnaces. The first story contains a hall 22’ 0” wide, which runs the entire length of the building, on one side of which are the dispensary proper (with a separate staircase to the laboratory below, and a special entrance from South Bennet Street), trustees’ room, laboratories, and one consulting-room, and the other side is divided into five consulting-rooms for the attending physicians. The second story contains a hall of similar dimensions to the one on the first story, with an ample and attractive staircase leading thereto, with operating, lecture-, and consultation-rooms, laboratories, etc., on one side, and five consulting-rooms for the physicians on the other.

The attic contains the janitor’s quarters (consisting of five rooms and bath-room), and a large unfinished apartment which can be used for storage, etc. The building is heated by two furnaces, in addition to which each room is provided with an open fireplace. The finish throughout is of ash, with floors of the best hard Southern pine. Soapstone sinks, with hot and cold water, are placed in every room, and the plumbing throughout is in accordance with the most approved sanitary rules. In point of construction, the building is second to none in Boston, great care having been taken to make it substantial and durable. The plaster work is applied directly on the brick walls, which are hollow, and the halls and rooms are well lighted by generous windows.

Ash settees, designed expressly for this building, are to be provided for the halls for waiting patients, and are to be so arranged that patients for each particular room will be seated facing and in close proximity to it. The walls of the building are of brick, with brown sandstone trimmings, surmounted by a slanted lipped roof with a gable on each corner. The chimneys have been so treated as to make an attractive feature of the design, and the whole presents an appearance both original and unique.
THE PREVALENCE OF TYPHOID FEVER IN NEW YORK.

Thus far in the current year the death rate of New York has been decidedly lower than usual, and there is abundant reason to hope that the record of the year will be completed without any noteworthy impairment of this gratifying state of things. As we stated some months ago would probably be the case, the cholera has not reached us; there is not time enough now before cold weather sets in for yellow fever to change the figures materially, even if there were much of a chance of its eluding the vigilance of our sanitary officials; scarlet fever and diphtheria can scarcely be expected to burst upon us in such sudden severity as to counteract the gain already made; and no city in the world is better prepared than New York for the speedy extinction of an epidemic of small-pox, of which indeed there is now not the slightest sign. The year is reasonably sure, then, to count as one of notably low mortality. No doubt the exceptionally cool summer now drawing to a close is to be credited in very great measure with this satisfactory showing, but it should not be forgotten that our Board of Health has, as usual, taken most praiseworthy precautions, and is fairly entitled to be taken into account in the summing up.

While, however, the favorable record we have spoken of is not likely to be reversed, there is danger of its being marred by the increasing prevalence of typhoid fever. It is seldom, to be sure, that an autumn passes without a considerable number of cases of this disease being met with among us, but this year the outbreak seems rather more threatening than usual. Typhoid fever is not one of the very deadly diseases, and it would be unwarrantable in the highest degree to expect it ever to take on the character of a pestilence in this community, but it is often the agencies that are not very terrible that slowly and silently work an amount of harm which proves great in the aggregate. Not only from this consideration, but because the disease in question is among the more easily preventable of all the zymotic affections, it is a pity that the utmost should not be done to limit its spread. We are convinced, by recent reports made public by the Sanitary Superintendent, Dr. Day, that individual members of the profession might do much more than they are now doing to aid the Board of Health in the work of stamping out the disease—and chiefly in the way of advising and enforcing disinfection of the excretions in cases of typhoid fever.

There are many gaps in our knowledge of atiology, and perhaps in few ways is this fact more forcibly if not strikingly shown than by the gradual renunciation that seems to be taking place of the general impression that contamination of the ingesta, and especially of the drinking-water, is practically the one and only channel of typhoid-fever infection. That the contagious may effect a lodgment in the system by way of the air passages, is, if we mistake not, coming more and more to be recognized. It is a legitimate corollary that the disinfection to which we have referred should be carried out promptly. Possibly there is little call for more stress in this direction among the well-to-do, but the case is different with the poor. We are aware that those of our own colleagues whose practice lies mostly in the tenement-house districts are overworked and miserably underpaid, but we feel sure that they need only be reminded of the gain to be effected by their giving a little stricter attention to enforcing the prompt disinfection of typhoid-fever excreta to lead them to co-operate in this matter most heartily with the well-directed efforts of the Board of Health. The board's circulars giving directions as to the best means of accomplishing such disinfection are explicit and simple, and certainly deserve to be followed by every practitioner.

THE INTERPRETATION OF COLLES'S LAW.

An interesting controversy on this subject has recently taken place between Behrend, of Berlin, on the one hand, and Diday and Doyon, of Lyons, on the other. The former, in a paper on "Inherited Syphilis," had held that the placenta might act either as the medium of infection between the mother and the fœtus, or as a barrier to such infection. Believing, therefore, that a healthy woman might give birth to a syphilitic child, he maintained that the mother would not necessarily escape infection from suckling her infant.

Regarding these propositions as in conflict with Colles's law, Diday and Doyon made them the subject of criticism in an article published in the "Annales de dermatologie et de syphiligraphie," in the fifth number for last year. In the February number of this year the controversy is continued by Behrend, in an article entitled "La soi-disant loi de Colles est-elle une loi ou non?" His Lyonnese antagonists follow with another, entitled "La lettre et l'esprit de la loi de Colles."

Behrend seeks to establish the following propositions: 1. That the thesis commonly called Colles's law is derived from a dogma of Colles's that has been interpreted incorrectly and amplified arbitrarily in the course of years. 2. That this law, as formulated by modern authors, is based upon a fallacy in logic, because deduced from a negative premise. 3. That, in the form given to it, the law is contradicted by direct clinical observations, since it has been established that a woman may contract syphilis by nursing a child that has inherited the disease from its father.

Behrend maintains that there is nothing in Colles's original proposition inconsistent with the assumption that the mother's immunity is acquired by prior infection, and he believes that that is the only way in which it could be acquired. Colles's words are: "It is a curious fact that I have never witnessed nor ever heard of an instance in which a child deriving the infection of syphilis from its parents has caused an ulceration in the breast of its mother." ("Practical Observations on Venereal Disease," London, 1837.) This statement, Behrend asserts, was afterward modified by Beaunès as follows: "A mother,
MINOR PARAGRAPHS.

Having borne a syphilitic child which "once its infection to the semen of the father, does not generally contract the disease in nursing her child, though a strange nurse may do so," Diday afterward mingled these two propositions in the following formula, which has since been 'generally adopted and known as "Colles's law": "A syphilitic child, whether inheriting the disease from the father or from the mother, does not infect the mother suckling it." Behrend's objection to this statement is, that it rests wholly upon negative evidence, and can stand only as long as there are no conclusive observations to the contrary. But, he maintains, there are three cases on record in which the mothers were infected from syphilitic children that inherited the disease from the fathers. They were reported by Ranke, Guibout, and Cazenave, and Behrend regards them as outweighing all the negative evidence that can be produced on the other side. In conclusion, he deprecates the advice, commonly given as a sort of "moral" to Colles's law, that the mother of a syphilitic child should always nurse it herself.

It seems clear to us that it was no part of Colles's intention to give an opinion as to how the mother's immunity was acquired; he merely recorded his experience. Had he been convinced, as Behrend is, that the mother's immunity was due to her having contracted the disease before the child's birth, he would doubtless have said so distinctly. There is perhaps a presumption that he had such an idea, from the remarks he makes about a case that at first seemed an exception to the rule. An infant a few months old suddenly showed signs of syphilis. At about the same time the mother's nipple became sore, and syphilis followed. Colles argued that the child had not inherited the disease, but had probably been infected by a woman whom the mother had allowed to suckle it, "because," he says, "as yet I have not seen any instance in which an infant infected by the mother communicated a venereal ulcer of the nipple to her."

The prior infection theory may be the true explanation of Colles's law, and in that case Colles's original formula would be much nearer the truth than any of its modifications. The strict correctness of the term "law" in this connection is certainly questionable, although the fact designated by it seems almost invariable. The three exceptions cited by Behrend, to two of which, by the way, Diday and Doyon offer grave objections, make but a poor show in the face of almost unlimited testimony on the other side.

THE COUNTY SOCIETY NOMINATIONS.

The most adroit move yet made in the code fight was made by Dr. Flint, Jr., last Monday night, when he placed so strong a nominee as Dr. Thomas squarely on the old-code platform. The result will be that Dr. Thomas's election, if it takes place, will be sure to count as a victory for the party, however convinced we may all be that it is really due to his immense personal popularity.

THE ACADEMY OF MEDICINE.

The President of the Academy, Dr. Fordyce Barker, has issued a circular to the Fellows, the effect of which, it is hoped, will be to take the vexatious question of ethics out of the Academy, by leading to the adoption of certain amendments of the constitution and by-laws which will be offered at the meeting next week. In his circular the President says: "The Academy of Medicine is not fulfilling its mission when it is engaged in warm discussions of questions of casuistry, in polemical controversies, or in medical politics."

THE ERIE COUNTY MEDICAL BILL.

We are glad to learn that the committee in charge of the medical bill proposed by the Medical Society of the County of Erie, the full text of which we published in our last issue, have modified their plan for a pro rata representation of the sects in the State examining board. The proposition now is, as we understand, to arrange the representation in the proportion of six non-sectarians, two homeopaths, and one eclectic.

OUR STUDENTS' NUMBER.

The "Maryland Medical Journal" remarks that we might have credited Baltimore with four colleges instead of two, and we have received communications from the officials of several medical colleges, some of whom intimate that their institutions were omitted from our list by design. We would refer these gentlemen to the following sentence in the introductory paragraph of the Students' Number: "The list includes all the non-sectarian colleges recognized by the Illinois State Board of Health that we have been able to obtain trustworthy data from."

A NEW MATERIAL FOR THE OBSTETRICAL FORCEPS.

An incident has lately come to our knowledge that hardly seems likely to strengthen the esteem in which some of our practitioners hold instruments of foreign make. A stock of instruments having been damaged by water, with which they were drenched on the occasion of the shop having taken fire, many of them were found to be useless. Among them was an obstetrical forceps that proved, on removing the nickel plating, to be made of brass. It was one of a lot that had been obtained some years ago from a Sheffield maker. Cast brass is much cheaper than forged steel, and we must certainly credit the Sheffield instrument-maker with being as "smart and knowing" as the Burgomaster in "The Czar and Carpenter."

YELLOW FEVER AND CREMATION.

A recent number of the "Kölische Zeitung" cites certain investigations by Dr. Dominques Freire, a Brazilian chemist, who professes to have discovered that the blood of yellow-fever patients contains a parasite which continues to live, in one shape or another, even after the victim's death. He therefore recommends cremation of the bodies of persons who have died of the disease. By means of experiments, he shows that the injection of a few drops of blood thus infected into the veins of a rabbit causes the animal's death within fifteen minutes. Although this result might be thought to be due to simple blood poisoning, it is noteworthy that the blood of a rabbit thus killed is found to be filled with the same parasite.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending September 25, 1883:
DISEASES. Week ending Sept. 18. Week ending Sept. 25.

Yellow Fever.—On Thursday of last week a dispatch was received at the Navy Department announcing that there were then no cases among the naval forces, but that ten civilians were under treatment, all but two being children. On Saturday one death was reported from Warrington. On Sunday two new cases were reported from the same place, both in children.

Cholera.—Up to the 26th of August the epidemic in Egypt had caused 26,579 deaths, of which 1,615 took place during the last week of that period. The European powers are reported to have agreed upon a conference at Rome to arrange an international sanitary code.

The late Dr. Beverley Livingston.—The Medical Board of the Nursery and Child's Hospital has adopted the following resolutions:

Whereas, The Medical Board of the Nursery and Child's Hospital receives with deep sorrow the announcement of the death of Dr. Beverley Livingston, at the beginning of what promised to be an association of unusual usefulness to the institution,

Resolved, That we, his associates, hold in greatest esteem our remembrance of the life and character of our friend, and desire to record our appreciation of his high attainments and skill as a physician, calling as they did from an ardent devotion to his selected life work, and our knowledge of his noble and elevated mind and of his generous companionship.

Resolved, That we see in the melancholy event of his death that our institution, the profession, and the community are deprived of the influence and example of a pure, true, and earnest life.

Resolved, That we tender to the family of our late associate our heartfelt sympathy in their bereavement, and that these resolutions be published in the medical journals of the city.

George G. Wheelock, Edward L. Partridge,
Committee.

Death of a Medical Student from Morphin.—Mr. Joseph W. Pilkington, Jr., of Sedalia, Mo., died in New York last week from the effects of an over-dose of morphin administered by himself. He was a student at the Bellevue Hospital Medical College, and is reported to have considered himself quite insusceptible to the action of opium.

Dr. William Osler, of Montreal, says the "Union médicale du Canada," has been made a Fellow of the Royal College of Physicians of London.

Professor Du Bois-Reymond.—The "British Medical Journal" states that the twenty-fifth anniversary of Du Bois-Reymond's appointment to the chair of physiology in the University of Berlin will be celebrated on the 15th of October.

An Honor to M. Jaccoud.—On account of his book on the treatment and curability of pulmonary phthisis, says the "Union médicale," Professor Jaccoud has been made a Commander of the Order of Christ, of Portugal.

The Death of Louise Laterau, the famous stigmatiste de Bois d'Haine, is announced.

The "Philadelphia Medical Times" is to pass under the exclusive editorial control of Dr. Frank Woodbury. Dr. Woodbury is admirably fitted to maintain the high character of the "Times."

The Medico-Chirurgical College of Philadelphia.—Dr. William S. Janney has been elected professor of practical anatomy and clinical surgery in the college. Dr. Janney is the present coroner of the city of Philadelphia, and is well known to the profession as an anatomist and surgeon of extended experience.

The Bellevue Hospital Ambulance Service.—The Commissioners of Public Charities and Correction have taken steps to secure the use of the telegraphic facilities of the Police and Fire Departments to improve the system of telegraphing for ambulances.

The Hunter's Point Nuisances.—Warrants have been issued by Governor Cleveland ordering the immediate closure of several bone-boiling and rendering establishments at Blissville and Maspeth.

The Maine General Hospital is reported to have received another gift of $80 from Mrs. Raymond, the singer.

Cremation in Philadelphia.—It is reported that the Medical Department of the University of Pennsylvania is about to build a crematory for the destruction of refuse from the dissecting-room, and that the structure will be at the service of those who wish to dispose of bodies by cremation.

A new Medical School at Beirut is to be established by the French, who have already expended 150,000£ on the building.

The Adulteration of French Wines, chiefly with coloring matters, has lately engaged the attention of our consuls in France, one of whom makes the serious statement that the publication of the reports of the municipal laboratory at Paris is to be discontinued at the request of a society of wine-dealers.

An Anti-vaccination Congress is now in session at Berne, Switzerland.

Doctors and Laboring Men.—It seems that doctors are not admitted to laboring men's unions, for the reason, as a laboring man lately stated to the Blair committee, that they are "too previous."

Letters to the Editor.

The Appeal to Medical Books in Court.

New York, September 15, 1883.

To the Editor of the New York Medical Journal:

Sir: Having noticed some remarks in a recent issue of your journal on the use in courts of medical books by lawyers in questioning expert witnesses, is my reason for writing this letter, hoping it may aid in calling attention to an evil which ought to cease. The bad features of this method were well illustrated in a recent case in the Supreme Court of Kings County. The counsel was allowed to read questions from a number of authors on insanity to the expert witness, and ask whether he agreed with the author or not. This in itself is not so bad, but it gives opportunity to the lawyer to do what this one did—viz., read so much of a paragraph as suited his purpose, thus often making the author say the opposite to what he intended to say, the Court being thus misled by not knowing the contents of the whole para-
resort to constitutional treatment, chiefly with the aid of mild local applications. It was always essential to remove every
known cause, and, as cigarette-smoking was a well-known cause of these nasal troubles, he advised that it should be at once
restricted.

Dr. F. H. Bosworth said the more he saw of throat and nas-
oral diseases the more he was convinced that the proper treat-
ment was not by the use of sprays, gargles, washes, etc., but by
the employment of such measures as would remove the organic
changes which are the cause of these affections. He had oper-
ated with very much greater frequency, and with more satisfac-
tory results, on the upper air-passages than on any other part of
the respiratory tract. He had not used the forceps very much,
and for the reason that he had had some very bad results after
employing it. He regarded the wire snare as a much more sa-
satisfactory instrument, and had not found it necessary to give
an anesthetic, except in very small children, when it was used.
He thought there was great danger in using the galvano-cauter,
on account of the liability to excessive inflammatory reaction.

Dr. Holmook H. Curtis had seen serious depression follow
removal of these growths with either the finger-nail or the for-
ceps. He had reached the conclusion that repeated scarifica-
tions of the flat adenoid growths which could not be removed
by the snare and spraying with a saturated solution of lodoform
in ether, together with constitutional measures, was the most
satisfactory method of treatment.

Dr. O. D. Pomeroy said that these growths were nothing
more than enlarged glands, and that it was not always necessary
to remove them, as, like the facial tonsil, they would disappear
if the existing catarrhal condition could be relieved by ordinary
treatment with spray. Of course, if they grew so large as to
act like foreign bodies and obstruct nasal respiration, they
should be removed. He regarded Jarvis's snare as the most efficient
means for removing the growths, and did not think that other
was necessary if the child was a large one. He thought it not
well to remove all the growths at a single sitting, because of
the liability to serious inflammatory reaction, which might extend
to the middle ear.

Dr. O. B. Douglas spoke of the reflex effects produced by
these growths, and mentioned one case in which the patient re-
ferred her entire trouble to the larynx; whereas, when the nasal
passages had been cleared out, the symptoms were removed and
the voice was restored entirely.

Dr. Bosworth protested emphatically against the heterodox
doctrine taught by Dr. Pomeroy, that these growths need not
be removed unless they gave rise to ear troubles. He regarded it
as one of the most dangerous conditions possible that could
be allowed to remain in a young person.

Dr. Pomeroy thought he put in a proviso concerning leaving
these growths.

Dr. Swinburne thought that the cautery could not be used
anywhere in the upper air-passages without producing an in-
flammatory reaction, but such as had produced any considerable
trouble he had not seen. He regarded the forceps as a bad in-
strument if the palate could not be controlled; but, if the palate
could be controlled, the entire growth could be removed with-
out injuring other parts at all, and he had not seen inflammatory
reaction follow the operation. He thought, with Dr. Bos-
worth, that in every case acute inflammation of the middle ear
was likely to result, terminating in perforation; and not only
the ear, but the general health was endangered by allowing these
growths to remain.

A New Hypodermic Syringe.—Dr. O. B. Douglas pre-
sented a new hypodermic syringe, made by Reynolds & Co.,
which he had found the most convenient of any he had ever
used.
AMERICAN GYNECOLOGICAL SOCIETY.
(Concluded from page 331.)

Third Day—Morning Session.

In addition to those present at the preceding sessions, the following-named Fellows were in attendance: Dr. T. Gaillard Thomas, of New York; Dr. James V. Ingham, of Philadelphia; and Dr. George J. Engelmann, of St. Louis.

Menstruation after Extirpation of the Ovaries.—Dr. Henry F. Campbell had prepared a paper with this title, of which he gave a brief oral summary. While conceding the preponderating influence of the ovaries in the menstrual function, he was inclined to think that there was a nervous mechanism, probably centering in the lumbar enlargement of the spinal cord, by the action of which, quite apart from "habit," periodical hemorrhages from the uterus might be brought about that were wholly indistinguishable from ordinary menstruation. The speaker traced interesting analogies from the effects of forced lactation in re-establishing the menstrual function and in overcoming sterility.

Dr. William Goodell, of Philadelphia, had found menstruation after removal of the ovaries very uncommon, but was quite ready to coincide with Dr. Campbell as to its cause when it did take place, the irritation being that caused by the ligature. In saying that menstruation was uncommon under such circumstances, of course he did not include the false menstruation that always, according to his experience, took place within a few days after the operation. When menstruation did return, it was owing, he thought, to the fact that some ovarian structure was left behind, and, on account of the occasional difficulty of re-moving all ovarian tissue by the vaginal method of oophorectomy, he had given up that method of operating.

Dr. Thomas Addis Emmet, of New York, related a case of his own, in which menstruation had continued after complete removal of the ovaries.

Dr. Henry J. Garrigues, of New York, referred to the occasional existence of a supplementary ovary.

Dr. T. Gaillard Thomas, of New York, thought the connection of the ovarian function with menstruation could not be regarded as yet accurately and minutely defined. In regard to Dr. Campbell's theory, he had no data. His impression was that menstruation after removal of the ovaries was exceptional. When it did take place, it was not true menstruation, but a metritis, due to the habit of the uterus, and was not continued for a great length of time. He had found the same results, in this respect, after Tait's operation as after Battey's. He related a case of supplementary ovary in a patient from whom he had removed the two other ovaries early in the summer, and concerning whose menstrual function subsequently he knew nothing. He was decidedly inclined to adhere to the old theory of ovulation as the cause of menstruation.

Dr. William H. Byford, of Chicago, thought our positive data bearing upon this question were very insufficient to serve the purpose of its elucidation. He agreed with what Dr. Thomas had put forward as to the facts generally observed, and also as to the ovulation theory. He had had only one instance of continued periodical hemorrhage from the uterus after removal of both ovaries, and in that case there was not the strict periodicity of true menstruation.

Dr. Matthew D. Mann, of Buffalo, had always held the views expressed by Dr. Thomas and Dr. Byford, but his experience in the class of cases under discussion had led him to attribute the flow to some diseased condition of the uterus. In one case, what seemed to be true menstruation persisted after removal of both ovaries, together with the whole body of the uterus, and was found to be due to the development of cancer of the cervix. He thought that reports of cases should not be accepted unless a thorough examination had been made to discover the cause of the loss of blood.

Dr. Campbell knew that the discharge was not always due to portions of ovarian tissue being left behind, but, of course, there might be a third ovary, although he had never seen one.

Afternoon Session.

Remarks on Chronic Abscess of the Pelvis.—Dr. Byford read a paper, largely based on clinical data, in which he depicted the serious consequences that often took place from extensive chronic abscesses within the pelvis in women, and detailed the methods he had found most successful in their treatment. A notable point made was the satisfactory results that he had met with from thorough removal of the layer of flabby, ill-conditioned granulations that often lined the cavity of the abscesses—tissue that it was extremely difficult to make take on a real reparative action. He had found that by removing it with a curette most gratifying results had been accomplished in several instances.

Dr. Thomas thought there was much original research displayed in the paper. Such abscesses should always be sought for, but, when they were situated high in the pelvis, it was not generally advisable to attempt to give vent to their contents by puncture unless there was very positive evidence as to the precise situation of the accumulation. The aspirator was a very bad means of treatment, and he had made use of it only as a means of diagnosis. He preferred an exploring needle, followed by a small bistoury sliding in the groove of the needle. His practice was now to keep the opening from closing by inserting a small glass tube with a flange. The cavity was then stuffed with iodiformed tow, which was changed daily, and isolated-phenol injections were employed. In many cases he had found it necessary to open pelvic abscesses above the brim of the pelvis.

Dr. Goodell was much struck with Dr. Byford's suggestion to use the curette in the cavity of the abscess, and thought it likely to be very serviceable. Where there was an opening above the brim, he passed a sound, made a counter-opening on its point through the vagina, and inserted a drainage-tube. Antiseptic injections were to be used; but he had found it necessary to be cautious in the use of carbolic acid for this purpose. Occasionally he had used the aspirator, but did not regard it with much favor. In one instance a furious inflammation had followed its use. He had resorted to the supra-pelvic incision in some instances.

Dr. R. Stansbury Sutton, of Pittsburg, Pa., had seen Esmarch scrap out abscesses with curettes.

Dr. Byford endeavored to encourage rather than repress granulations, and relied a good deal on the use of trtarate of iron and potassium to prevent the formation of flabby granulations, using it in the form of injections.

Dr. Byford admitted the danger of lighting up acute inflammation by exploratory procedures, and would inculcate caution in selecting for them only cases in which the abscess was chronic, and accompanied with well-marked fibrinous exudation. He, too, had opened chronic abscesses above the pelvis, but regarded it as a resource to be confined to desperate cases.

ERGOT: THE USE AND ABUSE OF THIS DANGEROUS DRUG.—Dr. George J. Engelmann, of St. Louis, read a paper in which he gave his experience in cases to which he had been called in consultation, and had had occasion to observe the evil effects of the administration of ergot by those previously in charge. The use of this drug he declared to be very wide-spread in his part of the country, and he felt that the harm it caused was so com-
mon that it would be well to banish it from obstetric practice altogether.

Dr. Joseph Tabor Johnson, of Washington, referred to a paper he had read before the society last year, in which he had called attention to the points that Dr. Engelmann had enumerated. He now wished to defend the profession from the sweeping charge that they always used ergot in labor.

Dr. Campbell almost always gave ergot in childbirth, but seldom before the birth of the child, and never before the full dilatation of the os uteri.

Dr. Albert H. Smith, of Philadelphia, thought the use of ergot in midwifery an unmitigated evil. There was always danger of its doing harm, and it never did good.

Dr. Ellwood Wilson, of Philadelphia, was astonished to hear Dr. Engelmann say that ergot ought to be banished from use in midwifery. He always used it in cases of placenta previa, and for the very purpose of causing tetanic contraction of the uterus. He always used it, too, in post-partum hemorrhage. For this accident, it was usually given too late and in too large amount. In cases of abortion, also, he always employed ergot, and had never met with any bad results.

Dr. Engelmann referred again to some experiences of his own that had led him to entertain the decided views he had expressed in the paper.

A Theory to Explain the Relaxation of the Vagina and Perineum During Labor.—This paper, by Dr. James R. Chadwick, of Boston, was read by title, the author having been obliged to return home before it was reached.

The eighth annual meeting was then declared adjourned. The next meeting will be held in Chicago, on Tuesday, Wednesday, and Thursday, September 23, 24, and 25, 1884.

NEW YORK OBSTETRICAL SOCIETY.

A stated meeting was held May 1, 1888, Dr. C. C. Lee, President, in the chair.

Tenaculum-Scissors for Trachezorrhaphy.—Dr. B. F. Dawson presented a pair of scissors with tenacular points for operations upon the lacerated cervix uteri. He had used them with satisfaction. The ordinary scissors often failed to take a satisfactory hold of the hard cicatrical tissue which existed in many cases.

Wire-Twister.—Dr. Dawson also presented a wire-twister with a sliding sheath upon the two blades, and claimed for it the advantage that it never slipped from its grasp upon the wire, and was simple in principle.

The President said that he had used the scissors presented by Dr. Dawson in one case, and they fulfilled the purpose perfectly. Care should be taken not to seize the tissue higher than it was desired to make the incision with the expectation that they would slip and fail to cut deep enough, like the ordinary scissors; they cut exactly where they were applied. With regard to the wire-twister, the advantage claimed for it, he thought, belonged equally to Sims’s if properly used.

Strangulation of an Ovarian Cyst; Rapid Decomposition of the Contents.—Dr. Dawson said that about five months ago a woman, thirty-six years of age, the mother of three children, consulted him with regard to an enlargement of the abdomen which he found to be due to a cyst of the right ovary, and which was causing her considerable suffering. For purposes of confirming the diagnosis, he inserted a hypodermic needle, and withdrew a slightly turbid fluid. The specimen sent to the microscopist for examination was lost. A few weeks afterward the hypodermic needle was introduced a second time, and fluid was withdrawn which was of a darker color than that withdrawn on the former occasion. The microscopist, Dr. Satterthwaite, said that it contained pus and blood. The patient was feeling better than before, and the tumor, she thought, seemed to be even smaller in size. Dr. Dawson, feeling that decomposition was taking place, directed her to return again within a short time, which she did, and the fluid withdrawn by the syringe was now found to be as dark as café au lait. Believing that the patient could not pass through the summer without relief, it was decided to operate immediately while the weather was cool, and she was admitted into the Woman’s Hospital and operated upon April 13th. The tumor was found to have only extensive and apparently recent attachments to the omentum and other abdominal organs. It was a polycyst, with thick walls, almost of a gangrenous color, and with chocolate-colored contents, about two quarts in quantity. It was found that the pedicle had become twisted, and this had cut off the circulation to such an extent that decomposition was taking place. The specimen was examined by Dr. Coe, of the hospital, who reported that the cyst showed commencing fatty degeneration and necrosis of the inner wall. The fluid contents contained Drysdale’s corpuscles, and a large amount of pus and blood. The corresponding tube, which was removed with the ovary, it was remarked, showed cilia in motion for some hours, a point simply of physiological interest. The right ovary was also diseased and, with the tube, was removed. Both pedicles were ligated and cauterized. The patient was convalescent.

Coccygeotomy.—Dr. Dawson also presented the bones of the coccyx removed from a woman, twenty-one years of age, who had suffered for four years very severely from general pericolic and uterine pains, for which she had undergone treatment by various physicians without benefit. Dr. Dawson found retroversion of the uterus, for which he employed treatment, but, as no relief followed, and it was found that the pain was referred almost exclusively to the region of the coccyx, which was movable and had sustained an injury from a fall three or four years before, it was decided to perform coccygeotomy. The patient had been doing exceedingly well since the operation a week ago. Dr. Dawson remarked that the operation for removal of an ordinary ovarian cyst was less tedious and troublesome than that for removal of the coccyx.

Dr. Garencius said it was a somewhat hazardous procedure to introduce the hypodermic needle into an ovarian cyst, especially when the contents were known to be undergoing degeneration, and withdraw only a small amount of the fluid, and it ought to be done with antiseptic precautions.

He had shown, in his book on the “Diagnosis of Ovarian Cysts by Means of their Contents,” that, if the cyst were tapped at all, it was safer to introduce the larger instrument and withdraw the whole of the contents, in order that the danger of after-escape of fluid into the peritoneal cavity and consequent inflammation might be avoided. Even when the smallest needle was introduced, and the cyst was not completely emptied, there was danger of some fluid escaping through the puncture and setting up peritonitis; whereas, if all the fluid were withdrawn, the puncture which had been made would heal perfectly before there could be a sufficient reaccumulation to distend the sac and escape by the opening. It was well known that a number of deaths had resulted from tapping ovarian cysts and not removing the entire contents. Dr. Drysdale, however, had made it a rule always to empty the cyst entirely upon tapping it; and probably he, working together with the late Dr. W. L. Atlee, had performed the operation oftener than any other surgeon, and had never had a fatal result. With regard to the movement of cilia in the Fallopian tube for some time, he once examined an ovarian cyst removed by Dr. Bozeman, in which the fluid was perfectly clear, and ciliary epithelium lined its inner walls, and in
that case the cilia were found in motion at least six hours after the operation.

The President said that Dr. Hanks had had a case which went to confirm Dr. Garrigues's statement with regard to the harmless nature of the large trocar when the entire fluid contents of cysts were withdrawn.

Dr. H. T. Hanks said that the case to which the President referred was one which he first saw about seven years ago. The patient had at first a polycyst, which had been tapped twice before he saw her. Since that time he himself had tapped the tumor ten times—with an aspirating needle three times early in his attendance on her, and of late with a large trocar. Even with this instrument, since several cysts were now present, and the contents had become so thick in some of these it was impossible to withdraw all the fluid, it had become necessary to make a number of punctures, and to pass the instrument, after its insertion, in different directions so as to reach the separate cysts. The patient was now seventy-eight years of age, and it was evident that the end was near.

Dr. J. B. Hunter remarked that he had had a similar case in a woman, sixty-eight years of age, who evidently had an ovarian cyst, which in the past four years he had tapped a number of times, withdrawing all the contents, and it had been done before he saw her.

Dr. C. D. Nicoll said it was not uncommon for patients with ovarian cysts to come to the Woman's Hospital with the history that the tumor had been tapped several times without any bad result.

The President said that in England the operation of tapping the cyst for diagnostic purposes was considered so serious that it was not undertaken without the surgeon being prepared to remove the tumor entire, if necessary, immediately afterward.

Tait's Operation.—Dr. Nicoll presented the ovaries and tubes removed from a woman thirty years of age. She had been suffering from pain in the region of the ovary during her entire menstrual life, and had of late become greatly reduced in health; all of the vital organs performed their functions in an unsatisfactory manner. The operation was done by Dr. Thomas this afternoon. Both ovaries were cystic, and the right Fallopian tube was much distended by liquid.

The President said that at a recent meeting of the society the opinion had been expressed that Tait's operation should not be resorted to in cases in which no symptoms existed except those of a subjective nature, such as neuralgia of the ovaries; that it should not be done unless positive evidence of disease of the ovaries and tubes could be discovered by physical examination. This he believed limited the field of the operation too much, and in support of this belief the following case was narrated, and the specimens were presented: A German woman, twenty years of age, single, entered his service in the Woman's Hospital three years ago, suffering from symptoms of chronic cellulitis and pelvic peritonitis. She was anemic, feeble, and somewhat hysterical, and her general health was greatly impaired. The slightest pressure over the pelvis and uterus caused pain. This was due in part probably to some degree of cystitis. She remained in the hospital about four months, undergoing the usual treatment for pelvic cellulitis; but, not being allowed to use opium to relieve pain, she became discontented, and went out and sought employment. In consequence of being unable to work, however, she lost one position after another, and returned to the hospital about a year ago. Dr. Lee had seen her from time to time, but all the treatment employed proved ineffectual. She was turned over to the out-door department, and Dr. Dawson was equally unable to give relief. Last winter they separately reached the conclusion that the only hope of relief consisted in Tait's operation, as it seemed evident that the ovaries were at fault, although this could not be demonstrated by physical examination. The patient willingly submitted to the operation, which was performed about three weeks ago. Both ovaries were found to contain numerous small cysts, and the tubes were thickened and inflamed. The temperature rose for one day to 101° F., but had since become normal. The operation was done without difficulty. In this connection he stated that the patient reported to the society, upon whom he performed this operation four months ago, who was then completely helpless, had since had perfect health, and was doing her regular housework. Besides these two cases, there were three others in which he had done the operation, in each of which benefit had resulted, although in three out of the five cases a sufficient length of time had not elapsed to determine as to the permanence of the result.

Dr. Hunter thought that the propriety of the operation was evident in the case reported by the President, and that the operation was called for in some cases in which an absolute diagnosis could not be made.

Puerperal Septicemia.—Dr. George T. Harrison read the history of a case, with remarks. [See p. 346.]

Prolonged Gestation.—Dr. W. M. Chamberlain reported further with regard to a case of prolonged gestation narrated at a recent meeting of the society. The patient was delivered on the 303d day after the close of her last menstrual period—one day less than ten calendar months, five days less than eleven lunar months; labor was very short and easy. The child was a female, weighing about eight pounds.

Dr. Nicoll was once detained in the city during the summer for about six weeks by a patient who was delivered on the 325th day after her last menstrual period, and who had had but a single connection, which took place on the fifteenth day after said menstrual period. The duration of pregnancy, therefore, had been 307 days. The child was puny and blind, but otherwise normal. It lived only a few months.

Dr. Garrigues thought that the possibility of pregnancy continuing for a considerable period beyond what was usual had been quite conclusively settled, both by observation of reliable persons and also by analogy drawn from the lower animals. Physicians could not accept the maximum duration of pregnancy as established by the laws of a country as having any scientific value except as going to show that at all times exceptional cases had occurred in which pregnancy had been prolonged beyond the usual period.

Henry J. Garrigues, M. D.,
B. F. Dawson, M. D.,
Frank P. Foster, M. D., ex officio,
Committee on Publication.

A stated meeting was held May 15, 1883, Dr. C. L. Lee, President, in the chair.

Tait's Operation.—Dr. B. F. Dawson related the following case and presented the specimen, consisting of the left Fallopian tube distended to the size of an egg, and inclosed with the ovary in firm false membrane. The ovary was atrophied from the pressure and constriction. About a month ago he was requested by Dr. Mary Jones, of Brooklyn, to see a patient, thirty-two years of age, married twice but never pregnant, who during her married life had suffered from severe dysmenorrhea. During the past three years she had suffered from pelvic neuralgia almost continuously, referred more especially to the region of the left ovary. Her suffering had compelled her to resort to opium in large quantity; she had become very delicate, and her general health was greatly reduced. An examination revealed great tenderness in the entire pelvis, exaggerated on the left side, where a small adherent tumor was discovered, evidently an
ovarian cyst or a hydro-salpinx. An operation was plainly indicated, and was advised by Dr. Dawson and desired by the patient. It was performed yesterday, May 14th, by Dr. Jones, Dr. Dawson assisting. He found the adhesions firmer than in any case in which he had operated, and it was with the greatest difficulty that he was able to remove the ovary with its tube, the seat of hydro-salpinx. The operation having been necessarily tedious, and the patient’s condition being low, it was not considered advisable to attempt to remove the right tube and ovary, which were apparently normal, but bound down even more firmly than the left had been. Moreover, the patient had referred her symptoms principally to the left side. Dr. Dawson thought that the pain, which was aggravated at the menstrual period, was intensified by the unyielding nature of the dense adhesions enveloping the distended tube and ovary. The patient gave a history of pelvic peritonitis five years previously, from which time her symptoms dated.

Dr. F. P. Foster asked, relating to the fear expressed by Dr. Dawson that fluid from the hydro-salpinx might have escaped into the peritoneal cavity, what amount of danger would attend such an accident?

Dr. Dawson thought probably the same amount of danger that would attend the escape of fluid from a simple ovarian cyst.

The President said that the question asked by Dr. Foster had been answered practically in the cases reported by Tait and Hegar, where fluid from a hydro-salpinx had accidently escaped into the peritoneal cavity and had not been followed by any bad results. Another practical question suggested by the case narrated by Dr. Dawson was as to whether an intelligent opinion could be formed from the history of a case with regard to the extent of the adhesions that might exist. It was doubtful whether, if the other ovary was diseased in the case related, the patient would be relieved of her symptoms.

Dr. Foster remarked that the question which he had asked had been suggested by the thought as to the possible advantage of puncturing the hydro-salpinx when removal of the organs was not practicable.

Dr. Dawson thought it was a good rule in abdominal surgery to avoid emptying any fluid from any growth into the abdominal cavity, if it were possible to do so.

The President thought that the immunity from dangerous symptoms which had been observed in many cases where the proposed operation had been abandoned after opening the abdominal cavity gave grounds for the belief that such progress would be made in explorative abdominal surgery during the next ten years as had been made, for instance, with regard to the operation of ovariotomy during the past ten years. He himself had witnessed five cases during the past winter in which an operation involving laparotomy had been abandoned, for one reason or another, after the abdominal incision had been made and the contents of the cavity had been explored. And in every instance the patient recovered.

Dr. J. G. Perry thought it might prove an important diagnostic point in the class of cases referred to by Dr. Dawson to know the exact period at which the pain began—whether before, during, or after the flow.

Dr. Dawson said that in the case reported the pain was continuously so severe that it would be difficult to reply to the question.

Dr. J. R. Goffe, present by invitation, said that Dr. Hunter, in performing Tait’s operation upon a patient at the Woman’s Hospital last winter, found, after removing the ovary and tube upon the side where pain had been most complained of, that the other ovary was so adherent he would not take the risk of removing it. The case was one of hydro-salpinx, from which the patient had been a great sufferer. She remained in the hospital five weeks after the operation, during which time there was complete immunity from pelvic pain. It was now just three months since the operation, and Dr. Goffe was informed by Dr. Hunter that a perfect cure had resulted.

**Solid Tumors of the Ovary; Removal of the Tumors with the Uterus.**—The Secretary read a paper by Dr. M. D. Mann, of Buffalo, detailing a case of this sort, and accompanied by the specimens. [See the journal for July 7th, p. 4.]

Henry J. Garbeges, M.D.,
B. F. Dawson, M.D.,
Frank P. Foster, M.D., ex officio,
Committee on Publication.

**NEW YORK SOCIETY OF GERMAN PHYSICIANS.**

A stated meeting was held January 26, 1883, Dr. E. Greening in the chair.

**Measles Followed by Typhoid Fever.**—Dr. Smibert reported a case of a child who had the measles and typhoid fever in close succession.

**Fatal Cases of Chorea.**—Dr. J. Rudisich gave the history of three cases of chorea with fatal termination, all of which he had observed at Mount Sinai Hospital. The first was that of a boy of nineteen years, from Wilkesbarre, Pa., who had been admitted to the hospital eight years ago. The symptoms were slight at the beginning, but, in spite of active treatment with arsenic, they increased in severity. The patient’s temperature rose to 104°, and even 106°. Chloral hydrate and other hypnotics were employed in order to stop the hectic and to induce sleep. Dr. Adler made a post-mortem examination, and found the vessels of the pia mater congested, punctiform hemorrhages in the gray substance, and edema of the brain.

The second case, that of a girl about fifteen years old, was similar in its course to the first.

The third case was that of a girl of the same age as the last, who had been in the institution twice. The first time she was under the care of Dr. Heineman, who examined her heart, but could not detect anything abnormal. When admitted for the second time she came under the care of Dr. Rudisich, who, upon examination of her heart, heard a systolic murmur, but found no enlargement of the organ. Either, hypodermic injections of morphine, and large doses of bromide of potassium were needed to control the violent jactitations. Two days before death the temperature rose to 101°. On the night before the fatal issue one eighth of a grain of hyoscyamine had to be given subcutaneously in order to produce sleep. At the autopsy made by Dr. Heineman, the pia mater was found to be congested, the cortical substance of the brain was stunned with minute hemorrhages, and there was stenosis and insufficiency of the mitral valve.

Dr. A. Jacob presented a case of a child eight months old suffering from intussusception. The infant had been sick for five weeks. It had on the average six passages a day, which at first had been greenish, but after the lapse of two weeks had become bloody and contained a considerable quantity of mucus. At the beginning of the child’s illness a tumor made its appearance in the epigastrum, and by degrees changed its place until...
it reached the hypogastric region. At the time of presentation it was ovoid in shape and of a soft consistence. With the finger introduced into the rectum to a distance of five cm., the tumor could also be felt. By bimanual manipulation it was ascertainable to be movable. The child resented examination only slightly. The temperature was 96.0°. It took the breast for the last time on the morning of the day of its presentation to the society. The rectum was stretched in the direction of its axis in the same way as Dr. Jacobi had noticed it in other instances where intussusception had taken place at a short distance from the lower end of the bowel. In the present case the completion of the process had taken fully three weeks, and this was the reason that the general condition of the little patient was not so critical as it might have been.

The mother, who was present, being asked whether any pus had been observed in the defecations, answered in the affirmative.

Dr. Jacobi then said that under these circumstances it was doubtful if the present case was not one of abscess in the abdominal cavity.

Dr. Scharllae remarked that the mother probably did not know the difference between ordinary diarrhoeal and purulent matter.

Speaking of the treatment of the case, Dr. Jacobi said that he would first try to effect the reduction of the intussusception by injecting a large quantity of water into the bowel while the child was under the influence of an anaesthetic. He considered it probable, however, that such a trini would prove futile, on account of adhesions which must have formed already, and that laparotomy could not be avoided. He had had occasion to perform this operation a year ago upon a baby only eight weeks old. Although there were no adhesions in that case, it took fully twelve minutes to disentangle the intestinal loops in order to get at the seat of mischief.

Syphilitic Paralysis.—Dr. A. Seessel related the history of a case of paralysis due to syphilis. The patient, a young man, was under the care of Dr. Guleke. He had had a chancre several years previous to the month of December, 1881, but did not notice any secondary symptoms. At the latter date, left-sided hemiplegia set in suddenly, without any premonitory symptoms and without loss of consciousness. Moderate doses of iodide of potassium rapidly improved his condition, so that after the end of three weeks he was able to walk about again. The patellar and Achilles reflexes, however, remained exaggerated.

Toward the end of January of the following year another attack of hemiplegia supervened, this time of the other side. There were no premonitory symptoms nor was there loss of consciousness. The use of the iodide was resumed, but with a negative result. Dr. Seessel saw the patient for the first time three weeks after the second attack. He found him to be a strongly-built man of thirty-three years. His mental faculties were unimpaired. The lower twigs of the right facial nerve were paralyzed, but there was no corresponding impairment of sensibility. There was right-sided hemiplegia, including the muscles of the neck, the back, and the abdomen. Sensibility and tactile perception were preserved throughout. The pulse was very rapid, and there was dyspnoea. His pronunciation was made somewhat indistinct by the impaired action of the muscular apparatus. There were also hiccuppe and a feeling of oppression in the precordial region. Within three weeks all these symptoms were relieved to a great extent by the use of iodide of potassium, mercury, and electricity. The patellar and Achilles reflexes, however, continued to be heightened. If the patient tried to stand on his toes, violent convulsions ensued. These clonic contractions of the muscles could not be stopped by pressure upon the large nerve trunks, but only by passing a strong induced current through the gastrocnemius muscles, or by dropping the heels forcibly upon the floor.

The seat of the disease in this case could only be sought for either in the inner capsule, or in the pons Varoli, or in the medulla oblongata. The combination of the facial paralysis with the hemiplegia pointed to disease of the first-mentioned locality; but the fact that there had been a preceding hemiplegia of the other side would render the hypothesis necessary that exactly similar processes had been going on in symmetrically disposed portions of the cerebral hemispheres. Such an occurrence would be very improbable; but, as it actually had been observed in one instance, it would be by no means impossible. The following symptoms militated against the presumption of the seat of the disease having been in the cerebral hemispheres: The impairment of the muscles of speech without aphasia or amnesia, the hiccuppe, the oppression in the region of the pons Varoli, the increased rate of the pulse, the dyspnoea, and the lesion of the muscles of the neck and of the back. An affection of the pons Varoli could not have produced homonymous paralysis of the facial nerve, neither could the absence of degenerative reaction (Entartungsausschlag) on the part of the paralyzed nerve be explained if the seat of disease was in that organ. The peculiar combination of the symptoms rather pointed to the pyramids as the seat of mischief.

According to Charcot, the heightened knee and ankle phenomena would forerun secondary contractures; but, as far as Dr. Seessel had been able to observe the case, there seemed to him to be no disposition toward such a result.

The rapid development of the symptoms spoke against the supposition of a tumor; but Dr. Seessel felt himself unable to say whether the symptoms were due to a gumma or to disease of the blood-vessels. Heuber, of Leipsic, had published a similar case, at the autopsy of which chronic pachymeningitis of the spinal cord and syphilitic degeneration of the blood-vessels were found.

Dr. J. Reimsch asked whether no abnormality had been found about the heart of Dr. Seessel's patient.

Dr. Seessel said no.

Dr. A. Seibert related the case of a man, fifty years of age, who, while playing cards, suddenly noticed formication in his right side, which had also lost strength. He gained his bedroom unsailed, though he had to ascend two flights of stairs. Dr. Seibert was called to see him, and found the power of the right arm considerably diminished and the left pupil dilated. The tendon reflex of the right side was increased. Ice was ordered to be put on the patient's head, and iodide of potassium was given internally. His condition did not at first improve, and after the lapse of four days both extremities of the right side had completely lost the power of motion as well as sensibility. Antisyphilitic remedies were persisted in, and under their use the condition of the patient was, in the course of time, considerably improved. Dr. Knapp at one time made an ophthalmoscopic examination, and, from the appearance of the fundus oculi, drew the conclusion that cerebral hemorrhage was present. The patient subsequently died from diabetes mellitus.

Dr. E. Greening remarked that there were no ophthalmoscopic signs known characteristic of either the presence or absence of cerebral hemorrhage.

Dr. Seibert added to the history of his case that there had been diplopia two days before the hemiplegic attack, and that the temperature taken at his first visit was 101°.

Dr. Seessel said that the latter circumstance excluded simple cerebral hemorrhage, as in such cases the temperature as a rule fell below the normal and remained so for two hours, after which time it again rose to the normal.

Gout and Diabetes.—Dr. Jacobi reported a case of gout
complicated with diabetes, and inquired whether any other members of the society had ever met with such a combination. He quoted from a recent work by Ebstein, who said that these two diseases might run parallel with each other.

Poisoning with Confectionery.—Dr. Alfred Meyer related cases of poisoning in two servant girls and several children by confectionery, of which he showed some. He had subjected a portion of it to the test with Marsh's apparatus and produced some of the deposits obtained. These deposits might be either arsenic or antimony. He did not employ the test to distinguish between these two, because he wanted to preserve the specimen for demonstration. He had no doubt that the confectionery contained arsenic, and not antimony, since there would be no occasion for adulteration with antimony, and the arsenic was evidently introduced with the coloring material. Tests had also been made for copper and for lead, but neither was found.

Dr. Jacom mentioned a case of a thirteen-year-old girl who, coming from school one afternoon, bought a pickle and ate it. She began to vomit immediately, and died the next morning. Examination showed that the pickle had been dyed with arseniate of copper.

A stated meeting was held February 23, 1883, Dr. L. Straub in the chair.

Infantile Convulsions and Eczema.—Dr. H. J. Boldt presented a child six months old for diagnosis. One night six weeks ago the mother noticed that the child's breathing was peculiar. She lit the lamp and found the child in convulsions. The eyes were turned upward, the pupils were contracted, and the arms stretched out stiff. After remaining in this condition for about one minute, the baby recovered and slept for half an hour. After a certain lapse of time another similar spell occurred, during which there was froth at the mouth. During the last six weeks the child had gone through twelve such spells. It also suffered from eczema, which seemed to improve every time the convulsions occurred, but only to relapse after every attack. The nature of the disease seemed doubtful to the doctor. Epilepsy could be thought of, but this disease was hardly ever observed in early infancy. At the time of presentation the child also had the whooping-cough.

Dr. Jacom examined the baby and found cranio-tabes and other symptoms of rickets. He thought that this was the cause of the convulsions, and that the treatment pursued ought to be chiefly directed against this condition of the system. He would lay special stress upon the child being frequently taken into the fresh air. He thought that if the little patient survived the next six or seven weeks, the chances of ultimate recovery would be increased, since it would then become more practicable to employ remedial agents.

Strangulated Hernia.—Dr. A. G. Gerster presented a child nineteen weeks old on whom he had performed kelotomy, combined with the radical operation for hernia, four weeks ago at the German Dispensary. The baby had been under the care of Dr. H. F. Kudlich, who had diagnosed the presence of right inguinal hernia and ordered the application of a truss. The mother failed to carry out this order. She applied to an orthopedic institution, where she was told that the child had no rupture, but something else, and where she was given a liquid with which she was to brush the parts. Evidently the condition had been mistaken for a hydrocele. The liquid, when used, caused an inflammation of the skin and the subjacent tissues. The protruded hernia was caught in the swollen tissue, and on January 23, 1883, symptoms of strangulation made their appearance. Dr. Kudlich saw the child the next day and immediately sent it to Dr. Gerster. It was brought to the latter on January 26th. He found the baby in a state of collapse. There was slight tympanitis, but no fever. The swelling in the right inguinal region gave a tympanitic resonance. No attempt at taxis was made, but the knife was at once resorted to. This happened to be dull, and the operator, having therefore to use more than ordinary force, inadvertently incised the intestine. The cut, which was parallel to the axis of the alimentary canal, involved about one centimetre of the peritoneal coat, but only nine millimetres of the mucous membrane. It was sealed by three catgut sutures, applied according to Lembert's method, i.e., without perforating the mucous membrane. None of the contents of the intestine had escaped. The external inguinal ring had to be nicked in order to reach the seat of constriction, which proved to be situated at the inner ring. The obstruction having been relieved by the knife, and the prolapsed portion of the small intestine, about eight centimetres long, having been found in good condition everywhere, especially at the place corresponding to the constriction, it was put back into the abdominal cavity. This was accomplished with some difficulty. At this juncture one of the catgut sutures by means of which the intestinal wound had been closed gave way and a small quantity of faecal matter escaped. The suture was at once replaced by another, and the hernial sac was carefully cleansed. After the reposition of the prolapsed intestinal loop had been accomplished, the neck of the hernial sac was closed by a constricting suture. No drainage-tube was used; the external wound was sewed up and dressed with iodiform. On the way home the child had a passage from the bowels. It nursed and slept well. The wound healed by first intention, and the child recovered without any mishap.

Dr. Gerster also related another successful case of kelotomy which he had performed at the German Dispensary. The patient, a very anemic and rachitic child two years old, had been brought to that institution on December 8, 1882, where the diagnosis of congenital hydrocele of the spermatic cord was made. The tumor could not be made to disappear. Four days later symptoms developed which raised a doubt as to the correctness of the diagnosis. An exploratory puncture revealed a feculent matter. No symptoms of strangulation had as yet been observed. Between December 13th and 15th the patient vomited each time he took nourishment. Constipation set in, and on the 16th the fluid vomited had a feculent odor, and the child was brought to the dispensary with high fever and the abdomen considerably distended. Kelotomy was at once performed. The prolapsed intestine was found glued to the sac, and had to be peeled off with the handle of the scalpel. Before searching for the place of constriction the parts were disinfected carefully. No trace of the exploratory puncture could be found. A catgut suture was passed around the neck of the sac, a drainage-tube was introduced, and the wound was closed. On the 19th the sutures were found to have given way, but there was no suppuration, and the wound looked as if it had been freshly made. Under the application of iodiform it healed without any further trouble.

Hydrocephalus.—Dr. H. J. Boldt presented a child fifteen months old with hydrocephalus. When six months old it was attacked with convulsions, and two physicians who saw it diagnosed basilar meningitis. Dr. Boldt first saw it five or six days after it had been taken sick. He found opisthotonus and dilated pupils. For the following three days the temperature taken in the rectum oscillated between 100° and 103° F. Dr. Janeway, who saw the child in consultation, held that it was a case of cerebro-spinal meningitis. The child recovered, and, after the lapse of two months, the cranial sutures began to widen and a well-marked hydrocephalus developed. The little one was now lively and nursed well, and the pupils reacted to light.
Tumour of the Abdomen.—Dr. Jacob presented a boy four years old whose abdomen had begun to enlarge last September. At the time of presentation there was considerable tympanites. Besides this condition, a rather large and firm tumour could be felt in the right hypogastric region which was scarcely if at all movable. Several smaller nodules could be made out in the neighborhood of the large tumor. Examination per rectum gave a negative result. The functions of the urinary apparatus and of the bowels were normal. There was an area of tympanic percussion sound between the tumor and the liver, proving that there was no connection between them. There was no history of inflammation of the peritoneum, and therefore the diagnosis of periphrytic exudation could be excluded. It was probably a case of multiple lympho-sarcoma.

Dr. Gesner, referring to the difficulty of diagnosis in cases of intra-abdominal tumors, mentioned the case of a woman who had a swelling in the abdominal cavity which an expert diagnostician thought was a sarcoma of the mesentery. When Dr. Gerster examined the patient he found the large intestine full of scybalia, which it took weeks to remove. When this had been accomplished the tumor had disappeared.

Dr. Jacob remarked that the boy presented had never suffered from constipation, and that therefore there could be no suspicion of an accumulation of feces.

Enormous Enlargement of the Prostate.—Dr. Isaac Adler presented the prostate gland and bladder of a man seventy-six years of age, with the following history: The patient, a strong and hearty man, had an attack of retention of urine eleven years ago, due to enlargement of the prostate gland and cystitis. A catheter was introduced and the bladder was washed out. After this had been done for several months, he discontinued treatment. Retention of urine again took place, and Dr. Adler was called in October 4, 1882. The enormously distended bladder reached above the umbilicus. A catheter was introduced, but it did not proceed further than the prostatic part of the urethra, where it seemed to burrow into softened tissues. After some time had been consumed in futile attempts to reach the bladder, aspiration was resorted to and a quartz of urine was removed in this way. This had to be repeated in the evening of the same day. Next day the attempts at catheterization were resumed without success. The prostate was enormously enlarged, so that the index finger introduced into the rectum could not reach its upper margin. There was neither stricture nor cystitis present, but it was evidently a case of senile hypertrophy of the prostate gland with consequent elongation of the urethra and thickening of the muscular coat of the bladder. After the aspirator had been used seven or eight times, it was considered necessary to establish a permanent opening for the discharge of urine. Of the two methods which could be taken into consideration, the suprapubic and the perineal, the latter was evidently impracticable on account of the condition of the prostate gland. Dr. Adler therefore, on October 6th, performed suprapubic cystotomy. The cannula of the trocar was left in the wound. The operator intended to replace it by a rubber tube as soon as sufficient adhesions had formed between the bladder and the surrounding tissues. The day following the operation bronchitis set in, with strong fits of coughing, which caused hemorrhage through the cannula. The patient became restless and nauseated, the abdomen was painful, chills, supervised, and he succumbed October 16th.

The autopsy showed that the septicemia had originated neither from the external wound nor from the false passages made by the catheter, but from a small wound in the posterior wall of the bladder, where the open mouth of a small vessel was discovered. This wound was caused by the cannula, against which the posterior wall of the bladder had been pressed during the fits of coughing. This vessel became the seat of phlebitis, which was the starting-point of septicaemia.

Should a similar case present itself again to Dr. Adler, he would operate in the following manner: After incising the bladder freely, he would wash it out and introduce a drainagetube. Then he would stitch the wound of the bladder, and, according to circumstances, also that of the skin, and apply an antiseptic dressing. In cases like the one related the peritoneum was pushed up so high by the fundus of the bladder that there was hardly any danger of peritonitis.

The prostate gland exhibited contained several myomata from the size of a filbert to that of a goose's egg. The prostatic part of the urethra was twice as long as normal, and was so much narrowed by the hypertrophic tissue of the prostate that the thinnest catheter could be passed through, even after the specimen had been hardened in alcohol. There were three small false passages in the anterior portion of this part of the urethra, each a fraction of an inch long, and perforating the mucous membrane, but not going to any depth beyond it. There had been no symptoms of irritation in the neighborhood of these false passages, nor in that of the incision. The bladder was comparatively small, and its walls were moderately hypertrophied. On the posterior wall the erosion mentioned above could be seen.

Metritis Disseminata.—Dr. Henry J. Garriques presented some specimens obtained from females suffering from metritis disseminata, of which disease he had seen six cases in all.

Myxo-sarcoma of the Axilla.—Dr. Gesner presented a specimen of a myxo-sarcoma as large as a fist, which he had removed by operation from the axilla of a young and robust butcher. The locality was a somewhat unusual one for such a growth. At the time of removal it was found to have started from the place of insertion of the latissimus dorsi muscle to the scapula, and to have pushed the large vessels of the axillary space in front of it. One portion of it showed a dark color, and it was at first feared that this was due to a melanotic nature of the growth. Upon closer inspection, however, the dark substance was recognized as extravasated blood, a hemorrhage having been caused by an exploratory puncture which had been made some time before the operation. A portion of the latissimus dorsi muscle had to be excised together with the tumor.

A. G. Gesner, M. D., Secretary.
Dr. A. G. Gerster presented the patient from whom he had removed the myxosarcoma shown at the previous meeting.

Cystic Tumor of the Uterus.—Dr. Paeo F. Munde presented an ovarian cyst which he had extirpated two months ago. The fluid contained in it was so clear that several of the physicians present at the operation expressed the opinion that it was a cyst of the broad ligament.

Cyst of the Broad Ligament.—Dr. Munde also presented a specimen of the contents of an abdominal cyst which he had evacuated by tapping. The patient was a woman, aged forty-two, who had had the tumor for nine years. She was somewhat inconvenienced by the weight of the growth, but her general condition seemed not to be affected by it. Before the operation the circumference of the abdomen, measured over the umbilicus, was forty-five inches. It was thought to be probably a cyst of the broad ligament. The quantity of the fluid obtained was thirty-eight liters. A microscopic examination of the fluid was made by Dr. Henry J. Garrigue, who corroborated the supposition which had been entertained in regard to the origin of the tumor. Cysts of such a size, exceeding that of a uterus nine months pregnant, are usually accompanied by general cachexia. The present case was an exception to this rule. She left the hospital a week after the operation, which was, in all probability, a radical cure, from the fact that cysts of the broad ligament hardly ever refill after being once tapped.

Taty's Operation.—Dr. Munde also presented ovaries and Fallopian tubes of a woman, aged thirty-nine years, who had been a patient in Dr. J. Rudilsh's wards at the Mount Sinai Hospital, and from there had been transferred to Dr. Munde's department. She suffered from severe and obstinate sciatica and other obscure neuralgic symptoms, involving especially the pelvis. She was a widow, and the mother of a ten-year-old child. There appeared to be some connection between her trouble and menstruation, and for this reason Dr. Munde proposed the removal of the ovaries and the Fallopian tubes. The patient assented to the proposition, which was carried out three weeks before the meeting. At the time of the presentation of the specimen the patient was convalescing as regarded healing of the wound, but no favorable change had as yet been observed in those symptoms for the relief of which the operation had been undertaken.

Pelvic Sarcoma.—Dr. Munde then showed a round-celled sarcoma of the posterior pelvic cellular tissue, removed after death from the body of a woman aged forty-two. The diagnosis of the case during life had been dubious. A tumor, showing uncertain fluctuation, had been felt, which pushed forward the posterior vaginal wall. It was tapped twice, each time yielding a small quantity of pus and blood. Subsequently, Dr. Munde made an incision by which he penetrated into a cavity containing about a quart of blood. The patient died shortly afterward. Dr. Munde had found no record of a case of sarcoma originating in the same locality as the specimen presented.

Enlargement of the Spleen.—Dr. Munde also reported the case of a female circus performer with a history of repeated attacks of intermittent fever, whose enlarged spleen reached nearly to the symphysis.

Dr. A. Schapfer had observed a similar case, also in a woman who had been attached to an equestrian show. Upon comparing notes, the two cases proved not to be identical.

Dr. J. P. Oehmke reported a case of lympho-sarcoma of the left inguinal glands causing death by metastasis.

A stated meeting was held April 27, 1888, Dr. E. Schottky in the chair.

Prolapse of the Uterus.—Dr. O. A. Von Ramdohr presented a woman with prolapse of the uterus, who wore a pessary invented by the doctor, which effectually retained the womb, and enabled the patient to walk about with comfort. An operation had been performed for the cure of the prolapse four years ago, but the cicatrix had yielded, and in six months the prolapse was again complete. He claimed that the pessary in question exerted no pressure whatever upon the symphysis.

Dr. B. Schlarab examined the case, and found that the pessary appeared to work very well. He thought, however, that it did press upon the symphysis.

Congenital Deformities.—Dr. H. J. Boldt presented several specimens of congenital deformities removed from the body of the child which had been exhibited to the society at its meeting of September 22, 1882, and which had since died, at the age of sixteen months. There had been a large protrusion on the right side of the body, which proved to be due to an enormous extra-peritoneal abscess. The left kidney showed fatty degeneration. The left suprarenal capsule had degenerated into a cyst containing from fifteen to eighteen ounces of fluid. As no trace of the right patella could be discovered during the life of the child, it had been considered wanting. Upon post-mortem examination, however, the missing bone was found on the posterior aspect of the right knee joint. The brain had been given to Dr. E. C. Spitzka, who was to present it at the next meeting of the society.

Dr. Boldt also presented a specimen removed from the body of a patient who had died of peritonitis.

Sublingual Cyst.—Dr. Richard C. Brandes presented a colored woman, twenty-three years of age, with a tumor of the floor of the buccal cavity. After having been present for fifteen years without giving rise to any noticeable discomfort, the tumor lately suddenly became painful, and began to increase in size rapidly. She then applied to the doctor, who made several incisions on both sides near the tongue, giving exit to about ten ounces of a mixture composed of blood, pus, and saliva. The swelling refilled rapidly, and a seton was introduced from the mouth. This procedure not producing the desired effect, at last an incision was made through the skin and a rubber drainage-tube inserted, which the patient wore at the time of presentation.

Dr. A. G. Gerster was satisfied that it was a case of a congenital cyst which had become the seat of inflammation.

Quintine Lozenges.—Dr. B. Schlarab presented specimens of lozenges prepared by Messrs. Reichert and Fingerhat, spathopharies, each lozenge containing two and a half grains of quinine tannate. They afforded a convenient means to administer the alkaloid to children, who took the lozenges readily.

Extra-genital Change.—Dr. Hermann G. Klotz reported the case of a woman, seventy-eight years old, who had a syphilitic rash over her whole body. The initial lesion was discovered on her right forefinger.

Dr. C. A. Von Ramdohr mentioned the case of a boy, nine years old, who suffered from a chancre of the prepucce which he had acquired in the regular way.

Collapse from Salicylic Acid.—Dr. B. Schlarab related that he had met with several cases of children who, after taking comparatively small doses of salicylic acid, were seized with symptoms of collapse similar to those observed in light cases of carbolic-acid poisoning. The doses had been too small to allow these symptoms to be explained by the action of the pure drug itself. He also said that the glass jars containing salicylate of sodium very often smelt of carbolic acid.

Dr. M. Engelsmann said that this was probably the case only where the salicylate had been prepared, according to the old method, from carbolic acid, which method should be abolished.

The question was then discussed whether the discoloration
of the urine was invariably the first in the train of symptoms of poisoning by carbolic acid or not.

Dr. A. G. Geister had seen four cases, which he reported, in all of which the dark color of the urine was the first phenomenon observed, while Dr. A. Skinner had seen one case, which he also reported, where other symptoms preceded the discoloration of the urine.

Dr. A. Jacott remarked that, according to Squibb, the salicylate of sodium kept well if protected from dampness. He was in the habit of prescribing the salt as kept ready in the drugstores, and had had similar experiences to those of Dr. Scharlau.

Dr. A. G. Caillé remarked that the smell of carbolic acid mentioned by Dr. Scharlau was possibly acquired by absorption of volatile particles by the salicylate of sodium. He alluded to the salts of bismuth, which are known to have the peculiar faculty of acquiring the smell of odoriferous substances placed in their vicinity.

G. A. Geister, M.D., Secretary.

**Miscellany.**

**Therapeutical Notes. The Prevention and Cure of Seasickness.**—J. Henry Bennett, M.D. ("British Medical Journal," Aug. 11, 1883), communicates his own personal experience in preventing seasickness, from which he had been a great sufferer in his early life whenever he was compelled to take a journey by sea. He discovered by accident that two cups of café noir, taken, with sugar only, an hour or more before embarking, entirely prevented the expected attack of seasickness on the occasion of a short but very stormy voyage. Subsequent experimentation on himself and others has led him to the conclusion that coffee, if taken according to specified directions, will entirely prevent seasickness on short voyages. By following this plan, he has himself enjoyed immunity from seasickness for twenty-five years. Moreover, "scores of his friends and patients" have found the plan equally effective. It is as follows: The coffee to be used must be of good quality. A weak or adulterated article will not answer. A medicinal infusion of about an ounce and a half, made by boiling for ten minutes in four ounces of water, will furnish a "dose" of about the requisite quantity and strength. As the use of chicory or other wish-wash will lead to insidious and exasperating failure, it is well to prepare the coffee at home, and carry it in a bottle or flask. It is to be taken about one hour before the voyage is begun, if sugar alone is added; if milk also is used, it must be taken about two hours and a half before leaving.

The object is to insure its entire absorption, and to leave the stomach empty when the start is made. Furthermore, the coffee should be taken on an empty stomach. However, to prevent exhaustion, a nutritious but easily digested meal should be eaten long enough beforehand to be well out of the way when the time arrives for taking the coffee. The latter probably acts by toning the nervous system, and particularly the sympathetic system, rendering the entire organism less susceptible to the peculiar disturbance of seasickness. "Probably strong tea, brandy, wine, indeed, any powerful nerve-stimulant or sedative, would have the same effect as coffee, if taken in the same manner—that is, sufficiently long before going on board to be absorbed, and to leave the stomach empty and quiescent." A full stomach at the beginning of a voyage, if there be any predisposition to seasickness, tends rather to cause than to prevent its onset. And the failure of remedial agents taken by the stomach is due to the inability of that organ to absorb them, after the malady has begun.

On longer voyages it is well to take the coffee as above described, and then to lie down. The action of the coffee will last for eight or ten hours, and during this time the system may become accustomed to the motion of the vessel. No food, liquid or solid, should be taken until there is a feeling of hunger or thirst. For the latter, a mineral water, soda or Apollinaris, with or without champagne or brandy, may be sipped. For hunger, café au lait, alone or with a little bread, may be taken, or other articles of food that have been recommended may be tried, for instance, curry.

For the continued sickness of long voyages experience has demonstrated the great value of injections of laudanum by the rectum. Fifteen to twenty drops may be given in an ounce and a half of warm water. If it is not retained it may be repeated in half an hour. Sleep, even in extreme cases, will usually be secured in this way, and during sleep the patient may become accustomed to the motion of the ship.

According to the experience of a naval surgeon, the best means of controlling confirmed desperate sickness is the constant drinking of lukewarm water. This is placed in quantity within the reach of the sufferer, who is to drink half a tumblerful when the sickness comes on. "It is immediately thrown up, but easily, and by and by calm comes."

**The Elimination of Mercury during and after its Cutaneous Administration.**—Dr. Schuster, of Aix-la-Chapelle ("Journal of Cutaneous and Venereal Diseases," September, 1883), has come to the following conclusions, from a series of more than a hundred examinations regarding the elimination of mercury in syphilitic patients during treatment by mercurial inunction and in patients who had been thus treated for from one to twelve years:

1. Mercury, administered by inunction or otherwise, is eliminated continuously.

2. This elimination, in ordinary cases, is completed after the lapse of six months.

3. Therefore there is no persistence in the organism of the mercury introduced.

These conclusions are opposed to the views held by Vajda and Paschkie, who believe that mercury remains stored up in the organism. This belief is based on the fact that, while mercury could often be found in the urine of those who were or had been under mercurial treatment, it could not always be detected, even in the urine of those who were actually undergoing a course of the treatment. Forty examinations of the feces were made by Dr. Schuster with the following results: Mercury was regularly present in relatively large quantities during the course of the inunctions (the earliest examination was made ten days after the treatment had been begun). Mercury was present in the feces for five months and a half after the inunctions had been discontinued; examinations were made at intervals of ten to fourteen days. Mercury was always present in the feces when it was present in the urine; on the other hand, it frequently could not be detected in the urine when it was present in the feces. After a prolonged course of inunction the amount of mercury in the feces was so abundant that at times it could have been determined quantitatively.

Dr. Schuster concludes, from the foregoing facts, that the elimination of mercury, after courses of inunction of from thirty to forty-five days, is regular and continuous; that it is completed within six months after the discontinuance of the treatment; and that there is no persistence of mercury in the system. He suggests that the failure to detect mercury in the urine when it is present in the feces may be due to the smallness of the quantity of urine analyzed. He admits that after very prolonged courses of treatment mercury might be found in the feces even eight months thereafter. As, however, in many examinations, made from eight to twelve months after the discontinuance of the drug, in cases where it had been used from two to twelve years, analysis failed to detect any trace of mercury in either the feces or the urine, he concludes that the elimination had been completely effected.

Vajda and Paschkie, in support of their view that mercury does persist in the system, profess to have found mercury in the urine two, three, five, seven, and even thirteen years after relatively short courses of inunction. Dr. Schuster criticizes this evidence thus: Admitting that mercury was detected in these cases, it does not follow that the mercury found was that introduced into the system two, three, five, seven, and thirteen years previously. The cases cited were those of patients who had been several days, to the number of thirteen in some instances, in the same syphilitic ward with from twelve to twenty other patients, nearly all of whom were using daily inunctions of mercury.

And, if analysis showed the presence of mercury, it is probable that
the subjects had inhaled the easily volatilized mercury that pervaded the atmosphere of the ward. Dr. Lessmann, of the Kalankin Hospital, St. Petersburg, states that in his syphilitic ward, while inunctions were used exclusively, stomatitis frequently occurred, not only in those under treatment, but also to patients to whom no mercurial preparation was given, so that the effect could only be ascribed to the effect of the mercurial vapors accumulating in the wards, which can not be removed by ordinary ventilation."

**Veratrum Viride in the Treatment of Puerperal Eclampsia.**—S. J. Spees, M. D., of Hillsboro, Ohio ("Cincinnati Lancet and Clinic," Sept. 1, 1883), reports an interesting case of puerperal eclampsia relieved by the use of *Veratrum viride*. The patient was a primipara, twenty-two years old, healthy, and of full habit. After labor had been in progress twenty-four hours, there had been but little progress even of the first stage, while all the symptoms of the eclampsia had steadily increased in severity. Venection had been resorted to, but without benefit. Turning was performed, and the woman delivered of twins. Delivery, however, did not relieve the eclampsia, but the condition of the patient became more and more alarming. Tincture of veratrum viride (Tilden's), m x, every one to three hours was given. Twelve hours afterward, m x xx were given every thirty to sixty minutes, when the patient could swallow. Warmth was applied to the extremities and cold to the head. There was marked improvement within six hours. The doses were then decreased somewhat in size and frequency. The improvement continued, and the patient made a good recovery.

**Army Intelligence.**—Official List of Changes of Officers serving in the Medical Department of the United States Army. From September 15, 1883, to September 22, 1883.—**CAMPBELL, Joseph**., Lieutenant Colonel and Surgeon, Medical Director, Department of the South. Granted leave of absence for fifteen days. Par. 2, S. O. 94, Department of the South, September 12, 1883. —**ALEXANDER, Charles T.**, Major and Surgeon. Granted leave of absence for four months from October 1, 1883. Par. 1, S. O. 213, A. G. O., September 17, 1883. —**ALEXANDER, Charles L.**, Major and Surgeon. **Naval Intelligence.**—Official List of Changes in the Medical Corps of the Navy during the week ending September 22, 1883. —**Passed Assistant Surgeon J. H. Bryan**, detached from the United States steamer Miantonomoh, and ordered to the Museum of Hygiene, Washington, D.C. —**Passed Assistant Surgeon A. P. Magruder**, detached from duty at Villefranche, France, and granted six months leave, with permission to remain abroad during that period. —**Passed Assistant Surgeon C. H. Hill**, to be detached from the United States steamer Ranger, on reporting of his relief, and wait orders. —**Surgeon J. L. Nelson**, detached from the receiving ship Franklin, at Norfolk, and ordered to the United States steamer William A. Corwin, ordered to the receiving ship Franklin, Norfolk, Va. —**Passed Assistant Surgeon Rob. Whiting**, detached from the receiving ship Wabash, at Ebris, and ordered to the Naval Hospital, Norfolk, Va.

**Society Meetings for the Coming Week.**—Monday, October 1st: Medico-chirurgical Society of German Physicians; Morrisania Medical Society (private); Utica Medical Library Association; Medical Society of the County of Monmouth, N. J. (Freehold). Thursday, October 4th: New York Neurological Society; New York Obstetrical Society (private); Medical Society of the County of Bronx (annual); Medical Society of the County of Westchester (semi-annual); Elmira Academy of Medicine; Buffalo Medical Association; Ogdensburg Medical Association; Medical Association of Northern New York (Malone, Franklin Co.); Croton Medical and Surgical Union (Katonska); Medical Society of the County of Hudson, N. J.; Medical Society of the County of Union, N. J. Wednesday, October 3d: New York Medical-Legal Society; Medical Society of the County of Richmond ( Stapleton). Thursday, October 4th: American Academy of Medicine (New York—first day); New York Academy of Medicine; Society of Physicians of the Village of Canandaigua. Friday, October 5th: American Academy of Medicine (second day).
Lectures and Addresses.

LECTURES ON
DISEASES OF THE KIDNEYS,
DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS.

BY FRANCIS DELAFIELD, M.D.,
PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE.

Lecture IV.

The Symptoms and Treatment of Acute Parenchymatous Nephritis.

Gentlemen: I was speaking at the close of the last lecture of acute parenchymatous nephritis, and I told you that this was a form of inflammation of the kidney in which the morbid changes were confined to the epithelium of the tubules and the epithelial cells lining the capsules of the Malpighian bodies.

Such a form of nephritis occurs both as a primary or idiopathic inflammation and as a secondary or complicating inflammation. As a secondary and complicating inflammation it is of very common occurrence. As a primary condition it is not so common, but it is not at all an unusual form of disease.

With pneumonia and typhus fever, typhoid fever, and the like, we very frequently have an acute parenchymatous nephritis added as a complicating lesion. But the nephritis in these cases does not usually take on any very great degree of intensity, or add much to the symptoms of the patient, or to the dangers of the disease, and there are hardly any symptoms of the kidney lesion, except the changes in the urine. With cholera and yellow fever, and acute parenchymatous hepatitis, or acute yellow atrophy of the liver, we may have added a parenchymatous nephritis in a very severe form, and here the kidney lesion is very decided, and it adds itself both to the symptoms of the general disease and to the danger of death. With scarlet fever, diphtheria, pyemia, acute peritonitis, and the like, and in persons suffering from poisoning by arsenic and phosphorus, we have a parenchymatous nephritis developed very frequently, but in different degrees of intensity. In some cases the nephritis is but very moderate in degree, and there are but very few symptoms, but in others it is very decided in character, and a matter of considerable consequence to the patient. In connection with the chronic and exhausting diseases, such as phthisis pulmonalis, septicemia, and malignant new growths in various parts of the body, we may have a parenchymatous nephritis developed, and sometimes we can call it an acute, and sometimes a chronic nephritis, for it lasts as long as the original disease, and manifests itself by changes in the urine; but there are no other symptoms.

As regards the idiopathic or primary cases, we know but little concerning their causation. Sometimes they seem to be provoked by exposure to cold and wet, but at other times no reason for them can be discovered.

In the secondary cases of acute parenchymatous nephritis there are usually some changes observable in the urine, even if there are no other symptoms of the kidney lesion at all. The quantity of urine remains unchanged in case the nephritis is not very marked, but, if it is very severe and acute, the urine is considerably diminished in quantity, or the function of the kidneys may be suspended altogether, and there will be no urine at all. The specific gravity of the urine is not much changed. Sometimes it is normal, and sometimes it is a little above or a little below normal. This is not what we should expect to be the case from our knowledge of the character of the lesion, for we should naturally expect that the specific gravity of the urine would be low, because the lesion involves principally the epithelial cells of the kidneys, and so we should expect that the solid matters excreted by these cells would be very much diminished. But in reality such is not the case, and so the specific gravity is not lowered. Albumin is very often present also, sometimes only a little and sometimes a very considerable amount, varying with the intensity of the inflammation. Casts are regularly present, usually of the hyaline and granular varieties, and not in very great numbers, but yet abundant enough to be found without great difficulty. Occasionally there will be a little blood in the urine, but not very often, except in the parenchymatous nephritis of scarlet fever, and sometimes in that of diphtheria. You are, however, especially liable to observe it with scarlet fever.

Dropsy is not often developed in these secondary cases. But the exception to this rule is where the kidney lesion complicates a scarlet fever; in these cases you do very often indeed see dropsy. But in other cases where the renal disease is a secondary lesion you will seldom find any.

Disturbances of the stomach, with nausea and a tendency to vomiting, occur in quite a good many cases, but it is always difficult to tell in these cases whether the disturbances of the stomach are due to the kidney disorder or to the miasma and primary disease.

Cerebral symptoms are developed in some cases in which the kidney lesion is very well marked. Thus, in yellow fever, acute yellow atrophy of the liver, scarlet fever, diphtheria, pyemia, and in phosphorus and arsenic poisoning, the cerebral symptoms seem to be due to the kidney affection. These cerebral symptoms are the ordinary ones which belong to the different forms of Bright's disease, namely, convulsions, delirium, headache, coma, etc.

In the primary cases of acute parenchymatous nephritis there are also symptoms. The urine is usually diminished perceptibly in quantity, and sometimes it is suppressed altogether. The specific gravity is not much changed. It does not vary far from the normal, but it may be a little above or a little below it. Albumin is usually present in these cases in very considerable amount, and, when the test is applied, a very large precipitate of albumin is thrown down. But, though this is the rule, we find some exceptions to it. In some cases albumin is only present in small amount even when the disease is quite severe. Casts are regularly found, and they are hyaline, granular, and epithelial casts. In some cases very few of them will be found, and you may have to examine several specimens and search
a long while before you find them. But in other cases they are quite numerous, and especially whenever epithelial casts are present. You may also have blood, which has come from the kidneys, present in the urine in moderate amount.

When you come to look at the other symptoms in these idiopathic cases of acute parenchymatous nephritis, apart from the changes which occur in the urine, you will find that they all seem to group themselves into three different sets of cases.

In the first set there are a good many cases in which the most marked symptoms are the development of dropical changes in the different parts of the body, disturbances of the functions of the stomach, and a loss of muscular strength, and with these there are the usual changes in the urine. The dropsy in these cases may reach a very considerable degree. Beginning usually in the feet or face, it extends rapidly until it involves the subcutaneous tissue of the feet, legs, and the whole body, and the fluid also accumulates at last in the various serous cavities of the peritoneum, the pleura, and the pericardium. In this way general anasarca spreads quickly over the whole body. There are also changes in the blood which show themselves by changes in the personal appearance. The face rapidly loses its natural color and becomes pale, the mucous membranes become white, the whole expression is changed, and the loss of color in the skin is rendered still more marked by reason of the edema in the subcutaneous connective tissues. There is also in this set of cases a marked loss of appetite, showing that the functions of the stomach are becoming disordered, then distressing nausea and even attacks of occasional vomiting are apt to set in, and the patient begins to experience a marked loss of muscular strength. These people do not always feel sick enough to be confined to bed, or even to stay in the house, but they do not feel competent to do any very extensive amount of work, either physical or mental. But, though their strength is so much impaired, yet there is not usually any emaciation or loss of weight, but they may be even larger than they were before.

In the second set of cases the most marked symptoms are the cerebral symptoms. There may be no dropsy at all, but the cerebral symptoms are the prominent feature, and these are stupor, sometimes alternating with delirium, repeated attacks of convulsions, and finally a comatose condition. Repeated attacks of vomiting are a very marked symptom here, and it may occur not only after taking food, even in the smallest quantities, but also after drinking water, and even when there is nothing in the stomach at all, and this constant vomiting is a very harassing symptom. At the same time dyspnea is often present, and it is the peculiar nervous dyspnea of the different forms of Bright's disease, and with all the other symptoms there is pretty well-marked prostration. The cerebral symptoms are particularly marked in this set of cases, and to these are added the repeated attacks of vomiting, the nervous dyspnea, and the rapid prostration, but there will perhaps be no dropsy at all.

In the third set of cases you have all the symptoms of the first two sets combined in the same case, namely, the dropsy, the changes in the blood, the nausea, the vomiting, the cerebral symptoms, the nervous dyspnea, and the prostration. So, then, you find that all cases group themselves into these three different sets—all, however, having the same kidney lesion, and all having certain of the symptoms of kidney lesions, but varying in different cases.

As regards the duration of acute parenchymatous nephritis, we find that in the secondary cases, where it is a complication of another disease, the kidney lesion and its train of symptoms continue as a rule during the whole course of the original disease; and as long as the pneumonia, or the typhus or the typhoid fever, or the scarlet fever, or other primary disease, lasts, so long does the kidney lesion with its symptoms continue. These kidney changes and symptoms make their appearance at different times in the course of the disease in different cases. In the case of scarlet fever the kidney changes are developed sometimes early and sometimes late, and the same is true with respect to pneumonia, typhus and typhoid fevers, and other cases. But when the renal complication is once established, its natural course is to go on to the termination of the original disease. If the patient recovers from the primary disease, and all the symptoms disappear, then, as a rule, the kidney symptoms also disappear after a little time—it may be within a few days, or not till after several weeks. But the kidney symptom that is especially apt to continue is the change in the urine, and this may not cease for some time after the apparent convalescence, not only from the primary but also from the kidney disease. In these cases the albumin and casts may be present in the urine, either in small or in large quantities for a time, and then completely disappear; but, though such an apparent recovery has taken place, the albumin and casts may recur again after once having disappeared, from the patient's being imprudent and exposing himself to cold or wet, and so lighting up a fresh attack. It is this case there will, perhaps, be some change perceptible in the general health for a while, and then the urinary symptoms will again disappear and the patient will probably get entirely well. The rule is, that an acute parenchymatous nephritis complicating another disease terminates ultimately in recovery if the patient gets well of the original disease. Sometimes recovery is very rapid, and sometimes it takes a long time. But occasionally such recovery does not take place, but the kidney lesion goes on and changes into the condition of a chronic parenchymatous nephritis, and then the kidney symptoms continue and persist for an indefinite length of time. So there is always this possibility, that the acute secondary kidney lesion will not be recovered from, but will go on and change into the chronic form of the disease.

When we come to the primary cases of acute parenchymatous nephritis we find that those cases in which there are marked cerebral symptoms are not usually of very long duration, and for the reason that they are apt to prove fatal within a very few days, though we do find cases that are not fatal for quite a number of days. But sometimes the result of the case is better than this, and the patient may ultimately recover, and in such cases the duration of the disease is longer, extending over a period of one, two, three,
DELAFIELD: LECTURES ON DISEASES OF THE KIDNEYS.

Oct. 6, 1883.

or four weeks, perhaps, and sometimes even longer. With those cases in which there is a combination of both cerebral symptoms and dropsy, the duration of the disease is apt to be not very long; for these cases are very prone to terminate fatally, and, in fact, they are the worst of all cases. Those cases in which the dropsy is the prominent symptom usually last for some time, and, after the lapse of several weeks or months, they terminate most frequently in recovery. These are the cases that are most apt of all to get well.

When we come to the treatment of this condition of the kidneys we find that, when the kidney lesion occurs as a secondary disease, there is very little that can be done in the way of treatment. In some cases the only evidence of the kidney trouble is found in the changes in the urine, and here, therefore, we only have to treat the original disease, and in those cases where other kidney symptoms are developed we still only attempt to treat the original disease. In the idiopathic cases the plan of treatment varies with the development of the symptoms. The class of cases in which treatment is most satisfactory is where the dropsy is the most prominent symptom. In these cases the dropsy is apt to be developed very rapidly; it is the first thing that attracts the patient's attention, and it continues to be very marked throughout the course of the disease. This, then, is a symptom that requires treatment. The first thing to be done with these patients is to put them to bed. Often they do not appear sick enough to feel like going to bed, or even to stay in the house, yet the bed is very much the best place for them, even from the first. The next thing to do is to put them on a fluid diet, principally of milk, or on milk and beef-tea alternating with each other. Then you may try from time to time the effect of cathartics and diuretics in diminishing the dropsy. In many of the cases where you give hydrargyrum cathartics at the end of the first week of the disease you will find that the patient will have a number of loose movements from the bowels, the dropsy will begin to diminish, he will pass more and more water constantly, and the dropsy will become steadily less and less. But in other cases, developed in the same way, though a number of loose movements may follow the administration of the cathartics, yet the dropsy is not diminished and the urine does not increase in quantity, and, in fact, the dropsy may become even more marked than before. If such is the case, there is no use in continuing to give cathartics at that time, but it is best to stop them and wait awhile before attempting to use them again. At the same time that you are giving cathartics you may try the effect of diuretics in increasing the quantity of urine and diminishing the amount of dropsy. If you find that by this means the urine is increased in amount and the dropsy diminished, you may continue the use of diuretics as long as they are indicated. But in some cases you will find that diuretics are not efficient, and under their use the urine is not increased in quantity and the dropsy is not diminished, and it may even be increased. Here there is no use in going on any longer with the diuretics, but it is better to stop them and wait a few days, and then try them again, as well as the cathartics, and see if they will have any better effect. So keep on trying them at intervals, and, when at length the kidney lesion has reached a condition favorable to their use, you will get decided effects from them, and not before; there is no use in crowding them for day after day if you find that they produce no effect soon after their first administration. In some cases you will find that the use of diuretics is accompanied not only by an increase in the production of urine and a diminution in the dropsy, but you will also find in a few cases that after you have got rid of the dropsy the increased production of urine still continues, though the diuretics have been stopped. The patient may still go on passing eighty, ninety, or one hundred ounces of urine in the course of twenty-four hours. You should try to diminish this excessive production of urine, for it is of no use to the patient any longer; and sometimes the easiest way to do this is to administer the tincture of the chloride of iron in considerable doses.

Then, besides getting rid of the dropsy and keeping the patient in the house and in bed, and helping the fluid to disappear, we have also to try to improve the condition of the blood, and this we do in the ordinary way by the use of iron and oxygen. Then, as the patient gets better and the dropsy disappears, and the need for diuretics and cathartics becomes less and less until you give them up entirely, you should still continue the iron and oxygen, and gradually change from a fluid to a solid diet; and at the same time you should pay proper attention to the skin, and keep it well-nourished by washing and rubbing it briskly every day.

When all the other symptoms have disappeared, there will usually still be a little albumin and a few casts in the urine for some time, and as long as these continue there is a possibility of a relapse and a recurrence of the dropsy and the other symptoms, and it requires considerable care to avoid this. If the disease occurs during the cold season of the year, then it is proper to send the patient to a warmer climate for the rest of the winter if he can afford it, and, if it breaks out in warm weather, these patients must take care not to expose themselves to wet or sudden changes in the weather unnecessarily.

The cases in which the cerebral symptoms are especially well marked are not by any means amenable to treatment. These are the class of patients that give you the so-called uremic symptoms; and not only this, but these uremic symptoms are very well marked, and come on in a way in which we seem to have but very little influence over them. There are, however, several different ways of trying to help these patients along. In the first place, we must try and feed them in some way; but the vomiting is often so persistent and uncontrollable that we find this a hard thing to do. So we must give them their food in very small amounts, such as a teaspoonful of milk every half-hour or every hour, and, besides this, we may give a little bicarbonate of sodium or oxalate of cerium, in the ordinary way, to control the vomiting. Then, again, we can try to make these patients sweat by putting them in a hot-air bath. But often this will not succeed, and, after remaining in for a considerable time, there will yet be no perspiration at all; but, if it
does succeed, so much the better for the patient. We can also try in other ways to induce a perspiration—that is, by the administration of pilocarpine or jaborandi. Pilocarpine in small doses hypodermically is, perhaps, the best way of administering these drugs. One tenth grain of pilocarpine once, twice, or three times a day, may be given, and in this way we try to get its specific effect on the skin rather than on the salivary glands. Then it is also well to try to act on the bowels so as to get free movements. But we find here, too, that the peculiar condition of the patient is sometimes such that ordinary cathartics will not produce any effect on the bowels. If, however, we can get free movements by them, so much the better for the patient.

The remedies we use commonly, in the uraemic attacks of Bright's disease, which are directed specially to the circulation, seem to be of no special service here, and those cases that get better at all seem to do so of themselves. Those cases where there are both dropy and cerebral symptoms are also very hard to treat, but we try to get rid of the dropy and the uraemic symptoms in the same way as in the other sets of cases. It is, however, very difficult to accomplish anything, and it is extremely hard either to sweat, purge, or feed these patients, or to produce any effect at all on the cerebral symptoms.

**THE STATUS OF THE MEDICAL PROFESSION IN THE STATE OF NEW YORK.**

By HENRY G. PIFFARD, M. D.

Sixth Article.

The seventy-seventh annual meeting of the Medical Society of the State of New York convened February 6, 1883, and was opened with the inaugural address of the President, Dr. Harvey Jewett, of Ontario County. From this address I extract the following:

At the annual meeting in February, 1881, this society appointed a committee of five, from among the most distinguished medical gentlemen of the State, to consider and revise the old code of medical ethics which had governed our action for nearly forty years. In conformity with the instructions given this committee, they presented their report at the annual meeting in 1882. At the same time a substitute was offered to this effect: that we abolish all restrictions relative to the practice of medicine, as superfluous and unnecessary in the presence of the unwritten or higher law, leaving all ethical questions to be settled by the gentlemanly instincts of the profession. The report of the committee, as well as the substitute, was printed and placed in the hands of all members of the society who desired a copy, that they might examine and vote deliberately and understandingly upon the changes reported for their consideration and adoption. After a general discussion, in which all present had an opportunity to express their views, the report of the committee was adopted by a large majority. The new code has not been received by the profession or the medical press, in this and in other States, with cordiality or favor, but, on the contrary, by the most outspoken and emphatic opposition. The county societies, at their first meetings, expressed their surprise at and disapproval of the new code adopted by a majority of their representatives, as unbecoming the dignity of the profession, and as revolutionary in its nature and "disorganizing in its tendency." A year's consideration, a calm and dispassionate discussion of the matter, have greatly modified the views of the profession in reference to the objectionable clause, and I trust a more conservative sentiment exists to-day than at the time of its adoption.

The American Medical Association, at its annual meeting at St. Paul, in June, 1882, refused admission to the delegates from the Medical Society of the State of New York, because they failed to recognize some of the provisions of the old code which had controlled their action for so many years, and had taken the liberty to substitute what was deemed a more progressive and liberal spirit in reference to established rational medicine as it exists at the present time. The objectionable clause in the new code consists in the permission of consultation with any legally qualified practitioner of medicine as not derogatory to the interest and dignity of the profession, in cases of emergency, or where such aid is required upon the broad ground of common humanity.

The advocates of the new code assert that this is merely permissive; that no one is under obligation, expressed or implied, to meet an irregular practitioner in consultation, unless he prefers to do so; but in certain cases it would be illiberal, inhuman, and contrary to the spirit of the age, to withhold professional aid because of "difference of opinion in creed or belief." The attention of the society at this meeting is directed to a consideration of the merits of this subject, to confirm, modify, or abolish the new code, as in their wisdom and judgment they may deem most conducive to the welfare, dignity, and interests of the medical profession of the State of New York.

At the conclusion of the President's address the standing committees of the society were announced, and after that communications from county societies, as the first order of business, were called for. The following were presented:

MEDICAL SOCIETY OF THE COUNTY OF WESTCHESTER, Katonah, February 3, 1883.

To the State Medical Society:
The following action was taken by the society at its annual meeting in 1882:

Resolved, That this society reaffirm its loyalty to its parent body, the American Medical Association, and thus declare its adherence to the code of ethics prescribed by that body as a guide in practice. It strongly deprecates the action of the State society, and maintains that such action is as unworthy as it is revolutionary; and that the adoption of such a code under such circumstances could result only in confusion and dishonor.

Resolved, That these resolutions be submitted to the State Medical Society at its next annual meeting through our regular delegates.

Carried. Affirmative, 28; negative, 2.

J. FRANCIS CHAPMAN, Secretary.

ROCHESTER, N. Y.

At the annual meeting of the Monroe County Medical Society, held in the Common Council chambers at Rochester, N. Y., May 31, 1883, it was

Resolved, That it is the sense of the Monroe County Medical Society that the code of ethics be repealed, and that the secre-
tary notify the Medical Society of the State of New York of the action taken.

William F. Sheehan, Secretary of Monroe County Medical Society.

Oswego, N. Y., January 31, 1883.

To the New York State Medical Society:

At the annual meeting of the Oswego County Medical Society, held in Oswego, June 13, 1882, the following resolution was adopted, and the delegates to the next meeting of the New York State Society were instructed to bring the same before the society:

Resolved, That, in regard to ethics of consultations, the true rule of our profession is that, while we should be free to visit the sick under all circumstances and under whose care, it is unworthy of us to call in consultation any but regular practitioners.

P. M. Dowd, Secretary.

After the transaction of some further business, Dr. E. R. Squibb, of Kings County, offered the following:

Whereas, The Special Committee on the Code of Ethics, in its report at the last annual meeting, recommended a change in one part of the code which was more in the nature of a revolution than of a revision, and, therefore, may be more radical than was expected or desired by the constituency of this society; and,

Whereas, That report was adopted at a session wherein only fifty-two members voted in the affirmative, and thus legislated for the entire profession of the State on a subject of vital importance in a direction which may not have been anticipated or desired by the profession at large; therefore,

Be it resolved, That all the action taken at the annual meeting of 1881, in regard to changing the code of ethics, be repealed, leaving the code to stand as it was before such action was taken.

Resolved, That a new Special Committee of five be nominated by the Nominating Committee of the society, and be appointed by the society to review the code of ethics, and to report at the annual meeting of 1884 any changes in the code that may be deemed advisable.

Resolved, That the report of the committee be discussed at the meeting of 1884, and be then laid over for final action at the meeting of 1885.

These resolutions were made the special order for the evening session. At this session the society went into committee of the whole, and Dr. Squibb opened the discussion, maintaining that the action of the last annual meeting upon the subject of the code of ethics was contrary to the plan of the organization of the society, and to the letter and the spirit of self-government by majority rule, and, therefore, ought to be reversed.

Dr. Squibb then went on to claim that the code of ethics was a part of the constitution of the society, and analogous to the constitution of the State, and that any amendments to be made in it should first be approved by the county societies.

Dr. Roosa, then taking the floor, said:

The Medical Society of the State of New York, as one of its inherent rights, has the power to make its own by-laws, and, by statute law, it has the right to call to the bar any county society which may refusing to cause its by-laws to conform to those of the State Medical Society. The argument, under the circumstances under which we meet to-night, is utterly absurd. What has happened? It is true that instructed delegates have come here from several county societies, and it is also true that from these very counties have come men who have been made permanent members, and who are entirely at variance with the instructions given to the delegates. It is a most unwarrantable doctrine that the city of New York, with its nearly two millions of people, and nearly two thousand regular physicians, that the county of New York, representing a constituency something like that of twenty counties in this State, is not to have her full and proportionate voice in the discussion and decision of any question which comes before us here. Because she has the misfortune to be a city, and a large city, is her vote to be counted only equal to that of Alleghany? I believe that this society is of one accord that the argument of Dr. Squibb is not sufficient for it, and that the State society is prepared to-night, whatever it may have been on previous occasions, to settle this question for itself, without referring it back to the counties. The State society undertook this action of revising the code, not as has been charged very frequently during the year, not at the suggestion of specialists, not by any arrangement beforehand. If there ever was a spontaneous convention on the face of the earth, if there ever was a convention which represented its constituents, it was the annual meeting of the Medical Society of the State of New York in 1889, and it has been equalled in the annals of this society only by the immense meeting of to-night. At that meeting this society not only passed the revised code, but, without caucusing or consultation with any person as to whether they could or would support it, it passed a resolution much more radical, which had not been presented to any person, except one, before it was offered to this society at that meeting. That meeting of the society did represent its constituency perfectly well, and so does the meeting of the society to-night. There was no unfair action of any kind in the meeting of last year, whatever may have been the statements from any source. It was an open discussion, and the distinguished gentleman who has opened the debate had his full say, and he was unable to convince even one third of the meeting that his views were correct. It is assumed in the argument of the gentleman that we have such a union with the American Medical Association that we are compelled to ask that association before we make any change in our by-laws. Perhaps that question has been sufficiently answered; but a large number are present to-night who did not hear the discussion which took place this morning on that part of the subject. Let us understand ourselves distinctly. We recognize no allegiance to the American Medical Association except that of fraternal relations, and in case they refuse to admit our delegates, as they refused to do last year, this relation is dissolved. That association is not an incorporated association. If we ever subscribed to its code, we repealed that subscription last year. The American Medical Association has not taken a position in the medical world to be compared with this society of which we have the honor to be members. There is no secession in this business. There is no States rights in our action. If the union of these States was no more than that which exists between the American Medical Association and this State Medical Society, there never would have been a rebellion. There would have been no need of one. Each State would have been independent, as we are now of the so-called National Association. The gentleman lays great stress on the adjective "revolutionary." Revolutionary! We are not afraid of that word. All the advances in the world have been made by revolutions; but revolutions are never revolutions except as they are monuments of the people, and a revolution in this society will never be successful unless we represent the voice of the medical profession of the State of New York. Not of us in New York can any charge of misrepresentation be made. The county of New York comes up here with its hands untied and without fetters, and any member is at liberty to vote as his conscience
may dictate. The county of Kings, thanks to great effort in opposition to the gentleman who has just spoken, is also unfettered upon this floor. But, I am sorry to say, I am addressing some gentlemen who never had an opportunity to listen to arguments on the side of those of us who believe that an advance of the profession will be most effectually promoted by our assistance to the resolutions offered to-night, and they come up here bound and directed as to what they shall do. I consider these instructions as utterly illegal; and, when I had the honor to be president of this society, I ruled that these instructions were invalid, and one gentleman from New York violated his instructions, and he was never disciplined, although he was threatened. No, Mr. President, not upon us can any charge of revolution be fastened except that which is similar to what has emancipated many a country, and which will emancipate the State of New York. The few other arguments which have been advanced against the new code are easily answered. It has been assumed by the friends of the old code that we have played completely into the hands of the homœopaths and the eclectics, if consultation with any class of legally unqualified be allowed. Now, if you are not willing to trust the ex-presidents of this society, who, with very few exceptions, are entirely in favor of this expression of freedom in consultation, and the committee, not of specialists, but of a majority of general practitioners who drew up this code—if you are not ready to trust them as to whether we are going to surrender in any such way, then I have misunderstood this society.

It has also been said that this is a medical question, and that it can not be in any manner understood by men outside of the medical profession. If this was a question as to the value of iodide of potassium, or sulphide of calcium, or the sulphate of quinine as agents for controlling the symptoms of disease, then none except men like ourselves, who have received a medical education and have had experience in its practical application, are competent to decide it. But it is not a question of drugs or drugging. It is a question of ethics, a question of man’s rights, his relations to his brother man, and his entire conduct toward the people of this community. The entire sentiment and conduct of the people is against this restricted trades-union clause in the American Medical Association code, and they have a right to their opinion, and are competent to give an opinion upon this question. The old code of our profession has made us the laughing-stock of educated men. We claim for ourselves, not the privilege of affiliating with quacks, but of giving our advice wherever it is asked for.

If we act simply as benefactors to our own kind, no matter if we stand alone for the next hundred years, we shall be right, and the Medical Society of the State of New York can afford to smile at those who refuse it fellowship.

Dr. H. G. Piffard, of New York, then said:

I desire to throw a little light upon one point raised by the gentleman from Kings. He drew an analogy between the constitution and by-laws of this society and the constitution and laws of the State. His special effort is to show that the code of ethics was virtually the constitution of this State society, and that it could not be altered except by the consent of the constituents from which the society is recruited. This view, I think, is erroneous. The code of ethics we have adopted is, and always has been before, regarded as a by-law simply. The gentleman from Kings County seems to think that we derive our authority from county medical societies, that we have no authority over them, and that our by-laws are subject to their revision, instead of their by-laws being subject to the revision of the State Medical Society. In that the gentleman is absolutely mistaken. He quotes from a certain law enacted in 1813, which gives us the power to make certain by-laws, and also gives county medical societies power to make certain by-laws, but he overlooks the fact that in 1886 another law was passed which enabled the State society to control the by-laws of county societies. In other words, county societies are amenable to this society, not this society amenable to the county societies.

Dr. H. R. Hopkins, of Erie, then addressed the Committee of the Whole.*

Dr. Didama, of Onondaga County, next spoke. Referring to the American code, he said:

...This code is the one which we adopted on condition of representation in the American Medical Association. If we repeal it, then we have no rightful representation in that association. It was repealed by a few, but their action was not the expression of the great mass of the profession of this State, only fifty-three persons voting one way, and they did not represent the opinion of four or five thousand regular practitioners of medicine in this State. There is a little complaint that our delegation—which was sent after our secession, if you choose to call it so, our enlisting ourselves loose from the American Medical Association—was not received with respect and open honor. But I think every fair-minded man must allow that the association could have done nothing else. They were bound to reject the delegates sent from a society which had repudiated the code of ethics established for the government of the entire profession. The question is, Are we, the medical profession of the State of New York, prepared to cut ourselves loose from the American Medical Association?

Dr. Didama further stated that he considered a consultation with a homœopath, with a person who believed in the efficacy of the so-called dilutions, as conniving at a fraud.†

In closing, he said:

With this I shall end, saying that a consultation with certain persons is derogatory to the medical profession, and that it is derogatory because those who do it are simply perpetrating a fraud.

Dr. Rochester, of Erie County, then spoke:

I arise with a full consciousness and appreciation of the soberness of this discussion to-night, and I hope that anything which I may say will be entirely free from personality. We have to look to common sense in this matter. I have been looking over this paper (State Code), and I have not seen any line of it which tells us what is to be gained by this proposed modification, except that broad humanity requires us to meet everybody who calls upon us. This I would say is simply a reflection on the medical profession throughout the length and breadth of the land, for there is no emergency, no calamity, no case of distress or anxiety to which medical men do not always go under any circumstances, without expectation of reward or remuneration. ... Now, sir, I am a permanent member of the American Medical Association, and I have been for a long time a permanent member of that body, as I am of this society, and I am proud of it, and I should be sorry to give it up. But I will say if this new code passes I will give up my membership in the State Medical Society sooner than my permanent membership in the American Medical Association.

Referring to mixed consultations, Dr. Rochester said:

We meet, we talk, but do not agree in therapeutics, very

* As Dr. Hopkins’s remarks have already been published in full in the columns of this journal, they are here omitted.

† See this journal for August 18, 1883, pp. 177, 178.
likely not in diagnosis, and the people are satisfied; but how is it with the patient? Does the patient get any benefit? Not at all. We say we can not see anything to do different from what is being done, and if we did suggest anything it would not be carried out. It is impossible for any such thing to take place. We can not do it without degrading ourselves. We maintain, then, our first position—that we are kind, generous, and liberal to all those who call upon us, and always have been, and I do not see any possible advantage which can come from this modification. Perhaps we are mistaken. Now, we know that while they are carrying these colors they are giving the very drugs that regular practitioners do, except that sometimes they give a little more.

Dr. Agnew then addressed the meeting, but, as his remarks have already appeared in the columns of this journal, they are here omitted.

Dr. Seymour, of Rensselaer County, then spoke to the question, but his remarks were too voluminous to be given in full, and will hardly bear condensation. We must, therefore, refer the reader to the official report. Referring, however, to certain members of the profession residing in a neighboring county, he said: "This thing will not do, and if you come up here to strengthen the hands of these men against us, we will arraign you before this society, and kill you off professionally; and, if you are backed up by your confère, we will twist their necks off too. That cock will not crow." During Dr. Seymour's remarks he was interrupted by the receipt of a telegram from Dr. L. A. Sayre of New York. Relative to this telegram Dr. Seymour said: "It is, perhaps, under the circumstances, hardly in order, but Dr. Sayre's name was mentioned, and then it was stated that he had met with homeopaths, and confirmed the new code, and violated the old code, and I took the liberty of sending a telegram to Dr. Sayre, telling him that the charge had been made; and I understood that a letter proving the charge would be read at this meeting, and called upon him to vindicate himself, and I got this telegram from some one in his house: 'Dr. Sayre has been confined to his bed for two weeks, and it is impossible for him to be moved at present. He says: 'I saw in consultation Dr. Baldwin, who was treating the patient most heroically all through. He had not diagnosed the case, and afterward I learned that he was a homeopath, although from what I saw of him no one would suspect that he was. He was at the time using hypodermic injections of morphine, and in no respect carrying out the principles of Hahnemann.'"

Dr. Seymour further said: "Once or twice in my life I have violated the code myself, and been to consult with homeopaths—once in a case of placenta previa, where the woman was bleeding to death. After I had righted things up, and got the woman so I thought she would live, I turned around to this homeopathic gentleman and said to him, 'You have abundant time now to consult with one of your own kind, and I will not trouble you any further.' For this consultation I was condemned, and I had to vindicate myself upon the principle of humanity."

This concluded the arguments on the question before the society. After some parliamentary skirmishing, the question was taken on Dr. Squibb's resolutions. The result of the vote showed 99 ayes to 105 nays, and the resolutions were declared lost. To carry them would have required a two-thirds affirmative vote, which in the ballot cast would have been 136.

The result of this ballot exhibited one fact with great distinctness—namely, that the majority of the representatives of the profession of this State were not in favor of a restoration of the old code. It had been repeatedly predicted by the hostile press outside the State that the action of the State society of the previous year would be reversed at this meeting. The vote showed, only too clearly, that, despite the exertions that had been made in behalf of the old code, and despite the abuse that had been heaped on us from without, the profession of the State were thoroughly convinced of the evil effects of the code in the past, and were not going to submit to them in the future, even at the expense of loss of representation in the American Medical Association.

Subsequent to the announcement of the vote, Dr. Roosa moved the adoption of his "substitute," which, on motion, was laid over until 1884. Dr. J. G. Adams entered a protest, as delegate from the New York Academy of Medicine, against the action of the State society. This protest was clearly an impropriety if offered in behalf of the Academy, and should not have been received as an expression of the Academy's feelings and views, inasmuch as a majority of the delegates of the Academy who were present voted with the majority. It may further be stated that the Academy had not expressed its views on the subject, and, as a curiosity in the matter of society by-laws, it may be stated that the members of the Academy have no direct voice in the selection of the delegates that are supposed to represent them, either in the State society or in the American Medical Association.

On the second day of the session the Committee on Legislation made its report, and during its discussion the question of ethics was incidentally revived. The committee having asked for an appropriation of five hundred dollars, for the purpose of procuring legal assistance, with the view to desirable legislation, Dr. Hopkins, of Buffalo, spoke in favor of the motion to adopt the report, to which Dr. Van de Water, of Onondaga County, replied as follows:

I did have great hopes for the cause of medical education in this State, notwithstanding the fact that nearly every attempt this State has made to regulate the practice of medicine has been a terrible failure—so terrible that, if medical men attempt to make laws, it is to be hoped that they will be such laws as will be of benefit to the profession. The law of 1880, which legalized every quack, was a deplorable failure, and the law of 1874, which gave the medical societies of this State certain powers, was another terrible failure, and, every time this society has attempted to dabble in medical law at all, the profession at large has deplored the fact.

Dr. Sturgis: I would ask the gentleman from Onondaga if any effort has been made in his county to prosecute illegal practitioners?

Dr. Van de Water: An Indian doctor rode through our principal streets the other day, adorned with war paint and feathers, and he registered in the Clerk's office, and is now considered a legalized practitioner, and he stands on the same footing with the other members of the profession.

Dr. Sturgis: Has any attempt been made to prosecute illegal practitioners in your county?
Dr. Van de Warker: Prosecution was not attempted in my county. . . . The legislation of 1880 was not to protect the regular practitioner, but to protect quacks, just as the code endorsed last night was not for the regular profession, but for quacks.

Dr. Sturgis: I do not think the gentleman can speak fairly of a point which has not been tried in his own county, and in which he has not had any experience. At all events, what he states is at variance with what has been the experience of the Medical Society of the County of New York, and the same is good for every county medical society in the State. When that law passed, the physicians of New York made up their minds to make a fair trial of it, and to determine wherein it was deficient, and to try to remedy its defects. We went to our county medical society and told them that the question was simply one of money, and that we needed money to employ legal counsel. We said to them, If you will give us your support, we will carry out the provisions of the law. The result has been that sixty suits have been brought, and in only three has the society failed to establish its case, and in every offense the man has been fined and driven out of practice. We got hold not only of irregular practitioners, but we have our hands on the throat of one of the colleges of this city. When the gentleman says that the law of 1880 protects quacks and protects irregular practitioners, he makes a mistake.

Dr. Smith (Secretary of the society): There is an opinion, widely prevalent in the medical profession of this State, that the mere fact of registration in the county clerk’s office makes a man a legally qualified practitioner. It does not such thing. The law requires the legally qualified practitioner in his registration to state the authority under which he claims to be qualified, and a person who has no legal right to practice medicine, if he registers under the law of 1880, will often furnish evidence in the statement he makes in his registration that he is not legally qualified; so that that law, instead of protecting quacks, often causes them to furnish proof whereby they can be convicted of practicing illegally.

The introduction of the questions relating to the law of 1880 into the code controversy, by the supporters of the old code, was irrelevant and uncalled for, as it had no bearing on the real issues under discussion. One may, perhaps, excuse words spoken hastily in the heat of debate, but we can not so readily overlook misstatements made in the calm seclusion of the sanctum. The following references to the law of 1880 are taken from the "Ephemeris" for May, 1883, pp. 279 and 280:

"The law entitled An act to regulate the licensing of physicians and surgeons, passed May 29, 1880, through the efforts of the New York County Medical Society," etc. (italics our own).

The fact is that the New York County Society had nothing whatever to do with this law. It was passed through by the efforts of a committee of the State society appointed for the purpose, and the entire expense of its passage, amounting to a little less than fifty dollars, was borne by the State society. The committee itself was composed of one member from Albany, one from Kings, and one from New York counties.

"This authorizing and licensing registry law, which, seen now in the light of more recent action, appears as the first public step taken in this no-code movement, levels all inequalities, and ranks the best names in the profession with those qualified for no profession and undeserving of recognition, whose lack of qualifications must be all the more dangerous to the public welfare for being legally authorized and licensed. This class, though legally authorized in a roundabout way, through diplomas and certificates of bodies incorporated under a general act, would never have been legally recognized and licensed but for this registry law, and the harm done by thus recognizing a large number will far overbalance the good of preventing the registry of a few, or the prosecution of a few who may be so incantual as to register fraudulently."

With reference to the foregoing, we are compelled to say that we do not remember to have ever read two consecutive sentences in which were to be found so many errors as to fact, and language so well calculated to lead to false inferences. If the writer in the "Ephemeris" had taken a little care to ascertain the facts, he could hardly have had the hardihood to refer to the registry law as the "first step taken in this no-code movement." The no-code movement, as we understand it, originated in a resolution introduced by Dr. Roosa, at the meeting of the State society in 1882. This movement has gained a considerable following, but, so far as we are aware, not a single one of the supporters of this movement had any hand or part in the passage of the Act of 1880. We further say that of those who did give their time and exertions to the furtherance of this registry law, not a single one has since appeared as an advocate of the no-code movement.

"Levels all inequalities." Every citizen, before voting at a general election, must in this State register his qualifications; but we fail to see that this brings down the statesman to the level of the pot-house politician, or the learned and virtuous to the level of the ignorant and criminal. In one respect only, not in "all," does it level. Just so the medical law levels in but one respect only, and in a very necessary respect, as it is the only means by which the State or any one else can learn the number or the qualifications of those who are legally authorized to practice within the borders of the State. The writer of this does not feel himself specially degraded by the fact that his name is on the same list with the names of physicians whom he may deem of inferior professional quality, any more than he does that his name goes on the same polling-list with those whom he regards as politically inferior.

The sentence, "This class, though legally authorized in a roundabout way through diplomas and certificates of bodies incorporated under a general law, would never have been legally recognized and licensed but for this registry law," etc., will bear a little analysis. It implies, first, that there exists a class of practitioners who should never have been legally authorized to practice. With this sentiment we agree heartily, but the reader should be made aware that the only incorporated bodies that granted these legal authorizations under "a general law" were the State and county societies acting in accordance with powers granted them by various statutes passed between the years 1806 and 1874. The reader might also have been informed that the registry law of 1880 revokes these powers so long possessed by the county societies, and which they in so many instances grossly abused. In the portion of the sentence that we have quoted there is a curious contradiction. The writer admits that a certain "class" were legally authorized by
certain "incorporated bodies," and then says that they "would never have been legally recognized and licensed but for this registry law." The fact is, the registry law did not legally authorize a single person to practice medicine who at the time of its passage was not already legally authorized in virtue of earlier laws (with an exception to be noted in a moment). The terms of the act are sufficiently explicit, and no misconception of their import should have arisen in the mind of any one who had read them.

To make this perfectly clear, we quote the words of the act, italicizing the portions that bear on the present question:

A person shall not practice physic or surgery within the State unless he is twenty-one years of age, and either has been heretofore authorized so to do, pursuant to the laws in force at the time of his authorization, or is hereafter authorized so to do as prescribed by chapter seven hundred and forty-six of the laws of eighteen hundred and seventy-two, or by subsequent sections of this act.

Every person now lawfully engaged in the practice of physic and surgery within the State shall ... register.

After the passage of the act, graduates in medicine only could commence the practice of medicine in the State. The exception that we alluded to a moment ago is in the case of medical students who had been in practice for ten years. These latter were accorded an exemption from some of the provisions of the act for a period of two years from the date of its passage. We doubt if there have been six persons in the entire State who availed themselves of this exception. It is to be hoped that the writer in the "Ephemerae" will in the future be a little more careful as to the introduction of irrelevant matters, and a little more accurate in his statements regarding them.

We regret the necessity for this extensive digression, and in our next will continue the historical exposition of the code controversy.

THE PATHOLOGY OF
ACUTE Lobar PNEUMONIA
FROM A NEW STANDPOINT.

BY WILLIAM D. SCHUYLER, M.D.

Third Article.

A Dynamo-physico-physiological Disease.—Its Pathogenesis.—Its Functional Pathology.

Having shown that the pathological process we are studying is not an inflammatory disease; furthermore, that it is not essentially a fever of an infectious or specific character, with a local, deprivative pulmonary lesion; and, lastly, that, contrary to general, and, as far as I am aware, universal pathological teaching, the local affection, the anatomical process in the lungs, is not due to an inflammatory action, is not an inflammation of the pulmonary stroma; I now announce and submit, and for the first time, that acute lobar pneumonia, in its genesis and throughout, is essentially a dynamic disease, a dynamo-physico-functional malady; dynamic as to the genesis of its initial lesion, physico-functional and dynamic as to the resulting development of its anatomical process and the cause and nature of its dangers.

It emphatically comprises a specific pathology, and can not be classed with any other affection.

Contrary to the tendency of more recent teaching, I shall show that the local affection is essentially the disease, and is the cause of the constitutional phenomena.

The determining, immediate cause of the local process, its incipient primary lesion, is a functional insufficiency—dynamics—of the pulmonary capillaries, few or many. This insufficiency may be regarded as an accidental occurrence; and the subsequent growth of the resulting anatomical process thus determined is the result of the necessarily continuing, but now deranged, vital functional actions.

A morbid agent, a materiae morbi in the blood, specific or diverse (one or a variety), can not be maintained as an indispensable cause for the genesis of this malady; although indirectly, as a predisposing condition, any morbid cause may lead to its development. From the standpoint of the hypothesis hereby advanced, acute lobar pneumonia is largely a preventable disease.*

The pathogenesis of this malady, although involving many and varied conditions, will be found to be very simple, to reside in adynamic or asthenic states on the one hand, and conditions of local blood-pressure, dynamic causes, upon the other.

The necessary adynamia is a local condition, and it may be limited as such, or it may so exist as a local expression of a general asthenia.

The causes which lead to the development of pneumonia, as usual and in general, are predisposing and exciting. The predisposing are: Any acute or chronic influences which conduce to or permit the development of a non-resistant, atonic, pulmonary capillary state—namely, age, exhausting conditions, malnutrition, nervous exhaustion from any cause (from labor, especially mental, with anxiety, and comprising long hours of watching, from great mental strain with deprivation of sleep); alcoholism, especially acute states, with its consequent derangement of nutrition, and resulting nervous debility and irritability further occasioned by loss of rest. Exhausting occupations, especially where such are followed under depressing influences, may lead to its development. Occupations in a confined, heated atmosphere, which promote debility of the skin and render it sensitive, or increase its reflex spastic tendencies, predispose the system to an attack. Also, acute and chronic maladies which create similar sensitive and irritable states of the cutaneous covering, such as ephemeral febrile states, rheumatic conditions, attacks of acute rheumatism, deranged functional action, which develop conditions known as bilious, diseases of the liver and kidneys, especially Bright's disease, are predisposing. Excessive indulgence in eating, with physical indolence, which develops a full habit and a fatty degenerate condition of the tissues, is largely predisposing. And, last-

* For the purpose of affording a more logical basis of explanation for this hypothesis, before proceeding to set forth its scheme, and give its more subsequent rationale, I shall briefly refer to pathogenesis, and give the pathological features of the affection. The latter will include especially its functional disturbances. Although involving some delay, this order commends itself to the writer as most natural, and in the end satisfactory.
ly, extensive traumatism, which especially depresses the nervous function, is a frequent predisposing cause.

The exciting cause of the development of a pneumonic attack may be any influence which suddenly determines the systemic venous blood inward upon the organically exposed, debilitated, and predisposed pulmonary circulation with such volume and pressure that the force and impingement transmitted shall overcome the existing tonic capacity of the pulmonary capillary vessels and render them for the moment insufficient for their function, and more or less atonic. A sudden chilling of an exposed and predisposed external surface of the body—the skin—the taking of cold, which results in an internal determination of the venous blood, as above set forth, may afford an example of an immediate cause, and is probably one of the most frequent. Over-repletion, causing a sudden augmentation of the blood volume, where there exists the adequate predisposing conditions, may prove an exciting cause. Vaso-motor insufficiency, sympathetic asthenia, as following traumatism, or from any cause, may inaugurate the process.

The pathology of this malady, in contradistinction to the simplicity of its pathogenesis, is most complex. It comprises: (1) A well-marked synthetic group of general symptoms, sufficiently characteristic in themselves to lead to the belief and teaching that the disease is essentially a constitutional affection. (2) It also comprises the formation and removal of a morbid anatomical process in the lungs, which is manifest by equally well-marked and not less characteristic physical signs. The magnitude of this local process in general and the dependence of the constitutional symptoms upon its progress have caused it also to be regarded as the essential of the disease. Also (3), furthermore, as comprising features of the highest clinical importance, in a prognostic sense, it involves such functional difficulties and dangers as justify a special reference to the morbid physiology engendered by it.

The constitutional symptoms and general course of the disease will be discussed under "symptoms and course." The local process will be studied under "morbid anatomy"; and therein its different events, with their connection and significance, will be fully set forth. Yet, as to the development of this process and its presence are to be attributed the physiological derangements and functional dangers alluded to, and, as its varied conditions of progress cause different degrees and kinds of functional stress, it is pertinent to state in this place with reference to it, to the morbid anatomy, that its process as such is eminently one of changing proportions, comprising, first, its growth, second, its decadence, and, lastly, its entire removal, in rapid succession, and that this changing character in volume and pressure is most important as exercising an influence upon the natural course of the symptoms, upon prognosis, and as influencing or governing the indications for its rational treatment.

It may again be referred to here, and as a unique feature, pathologically, of this process, that, considering the degree and extent of the action, its acute course, amount of exudate, and the dangers it involves, it should cause no sequelae beyond debility, both local and general, which, considering the duration of the action, is most marked. The functions referred to as involved, and more or less (some dangerously) jeopardized, are the circulatory, the respiratory, the nutritive, the sthenic, the excretory, and the nervous.

The circulatory function is especially affected by the morbidly deranged condition set up. (a) From an obstruction, and more or less complete inhibitory stoppage of the great systemic current of the blood in the pulmonary division of its course; (b) from a consequently deranged distribution of its blood-volume; and (c) from an equally deranged resulting local blood-pressure. The obstruction created results from direct and indirect causes: To the extent of the local process, which, as we shall see, so far entirely closes the pulmonary capillaries, it is direct; to the extent that the remaining pulmonary capillaries are inadequate to circulate the volume which arrives by the afferent vessels, it is indirect. The indirect obstruction will, therefore, where the volume of the blood is equal, be inversely in proportion to the local process.

Because of this obstruction of the systemic circulation at this point, a local aggregation of blood occurs upon the proximate side of the obstruction, which quickly results on account of the rapidly incoming blood in a markedly oppressive hyperemic condition, a congestive fullness or distension, which, as the blood collects, sets back upon or in the venous tract. On the contrary, and for the same reason, upon the distal, efferent side of the obstruction there results a corresponding anaemia. This local morbid fullness resulting upon the one hand, and the corresponding anaemia upon the other, which is continued in degree throughout the arterial system, constitute the deranged volume referred to, and equally set forth or imply the derangement of blood-pressure which is thereby created.

This deranged distribution volume is readily appreciated clinically in the empty pulse which is characteristic of the process, and in the venous congestion which is plainly apparent. The results of the deranged pressure will be pointed out later. The obstruction created varies with the varying stages of the developing local process, and also according to its final extent; it depends, furthermore, upon the resulting competency, or, on the contrary, the resulting embarrassment, of the collateral circulation.

In the inception of the process it is slight, its extent being only equal to the lumen area of the capillaries, which have become insufficient. As the process extends, however, through increasing functional (collateral), and, later, organic capillary insufficiency and consolidation, the obstruction also and equally extends and becomes more perfect; and if now the lung capillaries are further oppressed by an excited, morbidly developed, and adequate circulatory pressure, it may at any moment, in a full-blooded subject, amount to a dangerous inhibition, especially at a time just prior to the completion of an extensive consolidation.

The local fullness, hyperemia, and resulting pressure in the circulatory vessels, may not only cause great vascular stress, but are liable to cause right cardiac insufficiency while they remain. The symptom of cardiac diastolic present in pneumonia results from this cause; and a pulmonary inhibiting stress of pressure, in greater or less degree, is to be
attributed to the same condition. Furthermore, an obstructive filling of the afferent veins with carbonized blood, setting back, especially upon the brain, with pressure, may dangerously inhibit nervous action, and is, undoubtedly, the cause of the mental state of lethargy, oppression, anxieties, or delirium which may be present.

The respiratory function is not less jeopardized by the derangement and greater or less inhibition of its organs, the lungs. This derangement is often the cause of sudden death early in this disease. The pulmonary haematosic inhibition is due (a) to the consolidation of a portion of the lung structure or its antecedent condition, congestion; (b) to a resulting congestion and possibly edema of the remaining lung structure, from collateral action of the blood, and the pressure and pulmonary functional injury resulting therefrom; (c) to a morbid pressure, both lateral and direct, developed on account of the afferent filling with the incoming blood; and, lastly, to an excessive increase of weight due to congestion and exudation. To the extent of consolidation the haematosic function is completely inhibited; furthermore, according to the degree of collateral congestion, and especially structural edema, the remaining capacity of the organ for saturating the blood is interfered with. And the working of the organs, chemically and as an aid to the circulating blood by suction, is further impeded by the great additional weight of blood and exudate to which they are subjected; also by the pressure which is created, as will be more fully specified hereafter.

In addition to what has been said in reference to the results of fullness and pressure upon the nervous condition, this function is still further depressed and its action impaired by the effects of the process upon respiration and nutrition. The obstruction which is created or results, occurring just before the haematosic function is performed, leads to a great fullness — hyperemia — of carbonized depressing blood, and a corresponding anaemia of arterialized, stimulating blood. From a consequent need of the latter, and, on the contrary, because of the depressing, anaesthetic presence of the former — especially as the cerebral circulation requires and receives so large a proportion of the entire amount of the blood — nervous action is further depressed. Also, on account of the imperfect nutrition which results, this function still further suffers.

General nutrition suffers while the obstruction and local process remain: (a) on account of the resulting small quantity of oxygenated blood which is sent out to supply the organic needs; (b) because the blood which becomes arterial is still imperfectly oxygenated, and is deficient in elaborated nutritive properties or materials; and (c) because digestion is largely inhibited while the obstruction remains. As one result of the arterial anaemia which is created, the gastric and intestinal functions are not adequately stimulated; hence we may account for the well-recognized symptoms, anorexia and constipation, which are present. Furthermore, there result such apoplectic conditions as prove inadequate to digest the little food which may be taken. This inhibition of the function of the principal organ of nutrition works serious harm to the entire function; but intestinal and glandular pepsis is not less inactive, and so far increases the difficulty. The excretory functions also suffer from the same cause; owing to the diminished amount of arterial blood, constipation exists, and the urinary excretion is noticeably lessened.

Exhaustion occurs, therefore, with singular rapidity in this disease as compared with the same result in other maladies, and it constitutes a dangerous complication, which should not be overlooked. This fact of early exhaustion in pneumonia is of importance in affording an influencing indication for treatment, namely:

In the early stages, for conservative medication, rather for such treatment as shall restrain organic action, and, as far as possible, prevent unnecessary and harmful waste of vital force; in the later stages, for an opposite course, a liberal, active, and efficient tonic and supporting regimen.

(Book Notices.)

First Notice.

It was indeed time for another edition of this well-known work if its editor wished to retain its place among the standard surgical textbooks. Twelve years of advances in surgery leave a book far behind, and the last twelve years especially have been full of new facts and theories. The authors are compelled to acknowledge that even during the year which has been consumed in revising and printing this edition new matter has been added to surgical literature which cannot be found in the book. The object of the present edition is to bring the book up to date. Many of the original contributors have passed beyond the field of work, and their pens have been seized by younger hands. Of the remainder, some have rewritten their chapters and others have left them nearly as they were; but the work practically comes before the reader as a new one, and will be regarded as such. We notice in passing that the five volumes of the second edition have, in the third, been compressed into three; and that much additional matter has of necessity been added. This necessitates a change in the general appearance of the book, and, though the reader may miss the clear type and ample leading of the old edition, he will be compensated by the great reduction in price, which the close printing on cheap paper has rendered possible.

The first volume contains over eleven hundred pages, and is divided into the following chapters: Chapter I. is on inflammation, and is written by John Simon. (Unfortunately, his name has been entirely omitted from the list of authors, published on p. 29.) The second article is also on inflammation ("The Pathology of Inflammation"), and is by J. Burdon Sanderson. The first is on the pathology and treatment; the second is on the pathologic and etiology. Why this peculiar arrangement? On page 18 we have the causes of inflammation by Simon, and on page 92 we have the same thing by Sanderson. On page 3 we have "The Symptoms of Inflammation," by Simon, and on page 75 "The Objective Signs of the Inflammatory State," by
Sanderson. How well the different expressions for the same thing represent the differences in the style of writing by the two men! In fact, the original article in the first edition was written by Simon. In the second edition a part of it was cut out, and replaced by the article by Sanderson in vol. v. In the present edition the two have been brought side by side, Simon's remaining unchanged. The two, as they now stand, make a very complete though awkwardly arranged chapter on the subject, the part by Sanderson being intended to supplement that by Simon.

The succeeding article is on Abcess, originally written by Holmes Coote, and now rewritten by H. T. Butlin—or, rather, we do not know exactly who rewrote it. The table of contents says Butlin; it is signed W. Harrison Cripps. On further investigation, it seems to be Butlin, for we find him credited with it in the "list of authors"; but we can not be sure, for Cripps's name is signed to the next article, on sinus and fistula; but he is not credited with it in the list of authors and their contributions. The question as to who spent a year's time in correcting this proof is so obviously appropriate that we are inclined to omit it. The article itself is good. It deals not only with abscess in the abstract, but with the differential diagnosis and with the different varieties. Cervical abscess, abscess in the abdominal wall, mammary abscess, and suppuration in the palm, are studied in detail, with the treatment suitable for each.

The next article, on Sinus and Fistula, was originally written by Paget, in 1870, and, as we say, bears the signature of Cripps, in 1882. It is short (only five pages), and is devoted chiefly to the causation and treatment.

The next essay is on Gangrene, and is credited to its author, Cripps, all around. It replaces the article by Holmes Coote in the previous editions. The author divides gangrene into four classes: idiopathic gangrene, frost-bite, traumatic, and specific septic gangrene, and handles the whole subject in a concise, scholarly way, which makes very enjoyable reading. We notice only the omission of what Moore, of Rochester, has so well described in Ashhurst's "Encyclopedic" as "white gangrene."

The chapter on Ulcers, originally written by Paget, has been edited by Butlin, with slight alterations of the parts and a rewriting of the part relating to rodent ulcer. It is, we are glad to see, the same old classical chapter in the main, with the imprint of its author still plainly upon it.

The essay on Erysipelas was originally written by the late Campbell De Morgan, and has been revised by Holmes. The disease is clearly divided into its several forms, from an erythema to a diffuse cellulitis, and each is dealt with in detail. The remarks on contagiousness and treatment are especially valuable.

Pyemia and Septicemia are handled by Chatton in less than eleven pages. The essential difference between them is found in the presence of secondary inflammatory centers. Little is said of their etiology, except that they are both due to absorption of the products of putrefaction—the product being probably different in the two cases; but the author deals quite freely with the results of experiments on animals with bacteria, though he believes they need further confirmation. A vast amount of theory has been worked down in these few pages to its ultimate conclusion, with the result of saving much time and useless reading to the student.

In the essay on Hectic and Traumatic Fever and the After-Treatment of Operations we notice that the interesting point of the etiology of traumatic fever has been dealt with in very few words: First, bacteria; second, tension; third, nerve disturbances. The article is written by John Croft.

Tetanus, by the late A. Poland, revised by J. W. Hulke, is compressed into ten pages. The authors have little faith in any remedy, believing the disease to be self-limited, and that the powers of the patient must be supported in every way possible. They quote, however, a number of opposite opinions, referring with especial favor to the extract of physostigmin, hypodermically administered in doses of one sixth of a grain.

Delirium Tremens, by Dr. Barclay in 1870, has been rewritten by Warrington Haward. It comprises less than six pages, but all is given that is known as to pathology, and all that is of value in the diagnosis and treatment.

Mr. Savory's article on Scorfula in previous editions has been replaced in the present by one by Fred. Treves. It is, as it stands, one of the best in the book, and is illustrated by several microscopic drawings of scrofulous glands. The relations of scrofula and tubercle are discussed at length, as is also the nature of tubercle. The relation of scrofula to phthisis is considered, and much space is devoted to aetiology, as well as to the histology of scrofulous glands.

Savory's article on Hystera has been edited by Holmes, and Paget's on Tumors has been rewritten by Butlin. This latter covers forty-eight pages, with numerous illustrations. Passing rapidly over the chapters on Contusions and Wounds, both originally written by Paget and now revised by Croft, we notice simply the introduction of Mr. Lister's account of antiseptic treatment, which, in the second edition, was to be found under the head of amputation. The article on Animal Poisons, by the late A. Poland, is now by W. Anderson, and that on Wounds of Vessels, by the late Charles H. Moore, has been edited by Holmes. The chapter on Hydrophobia is entirely from the pen of Mr. Anderson, and is very complete. The disease in the lower animals is first fully described, and then the disease in man. As a whole, the article is the most satisfactory of any we now recall upon this subject, as are also those on Glanders and Foot and Mouth Disease. Under the head of Wounds of Vessels the editor has first considered haemorrhage, the haemorrhagic diathesis, and the treatment of haemorrhage, including transfusion. The chapter is a purely general one, and does not include the wounds of special vessels and the operations necessary for their relief.

The first part of the work closes with Mr. Savory's article on Collapse, and the general effects of shock upon the system. When the reader considers that this first part covers less than 400 pages of the first volume, and that there are three volumes of about 1,000 pages each, some idea of the enormous amount of material gathered together may be gained.

Part II includes Burns and Scalds, and Accidents by Lighting, by the Editor; The General Pathology of Fractures, by Hornidge, rewritten by W. H. A. Jacobson; The General Pathology of Dislocations, by the Editor; and Gunshot Injuries, by Surgeon-General Longmore. The chapter on burns and scalds is exhaustive, while that on fractures includes everything except the treatment of the special varieties. The process of union is particularly well described and illustrated, and non-union and vicious union are both ably treated. The chapter on Dislocations, by the same writer (Holmes), is of necessity much shorter, but is equally good. Over 100 pages are devoted to Gunshot Injuries in all their special varieties.

Part III is devoted to Injuries of Special Regions. The head, neck, face, back, chest, abdomen, pelvis, upper extremity, and lower extremity, each has a special chapter, and we notice the names of some new contributors. Prescott Hewett's work has been edited by Hulke, Shaw's has been rewritten by Jacobson, who has also supplied the place of the late Holmes Coote in the article on the face. Mr. Lyall, who edited the work of the late Alfred Poland on the Chest, also died while his work was going through the press.

In passing over this mass of matter, which ends the first vol-
ume and which includes the special fractures and dislocations, we will refer especially only to the excellence of the articles on fracture of the spine, trephining the spine (with a table of 180 cases), concussion of the spinal cord, injuries of the neck, wounds of the heart, foreign bodies in the heart (with a table of forty-seven cases), and rupture of the various organs. From so much good matter it is difficult to select the best.

We congratulate the author upon his ability to say that “the rapid exhaustion of a large edition of this work, the favorable comments which it has received from the periodical press, its translation into the Russian language, and the fact that it has been out of print for several months, constitute valid evidence that it has filled the void for which it was originally designed.”

Mr. Harrison’s little book will be read with interest by Americans, chiefly for the sake of the author’s intelligent appreciation of Bipelé’s operation, which he was among the first to advocate in England. The work includes also an account of the author’s method of tapping the bladder through the perineum and prostate.

Correspondence.

LETTER FROM VIENNA.

The Advantage of the Summer Courses.—Two Cases of Rupture of the Uterus.—The Use of Salt Solution in “Transfusion.”—Gastro-enterotomy for Cancer of the Pylorus.—Resection of the Pylorus.

VIENNA, September 15, 1883.

With the advent of cool weather, Americans are flocking here from all quarters to begin their winter studies. New courses are opening each week, and no one need complain of a dearth of occupation, although it is still two weeks before the opening of the semester.

The advantages enjoyed by those who remain in Vienna during the summer were mentioned in a former letter, and they are proved by a comparison of the courses now in progress with those of a month ago.

A class in operative obstetrics which then numbered ten is now increased to thirty—which means a decided decrease in the amount of personal attention given to each individual by the instructor. This disposition on the part of some of the assistants to increase the number of their students to such a degree that the financial element seems to be the only one taken into consideration has already been alluded to. Unfortunately, the number of really limited classes now is small, and profitable special studies must be pursued in small private classes at a heavy expense.

In the lying-in wards the advantages enjoyed by the individual are lessened in a corresponding degree by the autumnal influx of students, so that if I question a foreigner would not find that two months devoted to obstetrics in the summer repaid him better than an entire winter semester spent in jostling among a crowd of equally eager competitors, each anxious to purchase the favor of the assistants.

There are not usually so many interesting cases during the vacation, but the student will have ample opportunities for that personal observation of the phenomena of labor which is of the highest practical value to the physician. While referring to the subject of obstetrics, it may be of interest to recall two cases of rupture of the uterus which have occurred in Brauns’ wards during the past three weeks. In both instances the patients were brought to the hospital in a state of collapse some time after the accident. In the first case (a neglected transverse presentation) the fetus had partially escaped into the abdominal cavity. Turning and extraction were promptly effected, and two large drainage-tubes were introduced into the cavity through the rent in the posterior uterine wall, their ends being allowed to protrude from the vagina. No other treatment was employed except the use of morphine and ice-compresses (the latter being considered here the best prophylactic against peritonitis). The patient has completed her third week without a bad symptom. The second patient was brought to the hospital yesterday in a moribund condition after ineffectual attempts had been made to deliver by the high-forceps operation. Turning and extraction were performed with difficulty, owing to a narrow anterior conjugate. The woman died a few minutes later, in spite of attempted restoration by transfusion. At the autopsy an extensive rupture of the left lateral wall of the uterus was found extending through the cervix and vagina. It may not be known to all of your readers that in “transfusion” (an operation in poor repute in the Vienna school) blood is no longer employed here, but a weak salt solution, which is found to be quite as effective, and may be kept always at hand. You will pardon me for devoting so much space to this subject. I mention it not only to show the wide range of rare and interesting cases which are met with here in a short time, but because, as a spectator, I have been impressed with the promptness with which formidable complications are recognized and treated, even by the youngest assistants.

Dr. Wölfer (Billroth’s assistant) recently attempted a resection of the pylorus for carcinoma, but the disease had advanced to such an extent, and there were so many adhesions to surrounding organs, that the intended operation could not be completed. A fistula was established in the stomach and united to a loop of the small intestine, with the hope of establishing a permanent connection. The patient survived only a few hours. The same operation is to be repeated this week. In spite of the unsuccessful termination of most of the cases of resection of the pylorus, the operation seems to be gaining ground, though not regarded with much favor by physicians of a non-surgical tendency. It will be conceded by the most enthusiastic surgeon that it is much easier to diagnose carcinoma of the pylorus than to distinguish between cases in which operative interference is and is not justifiable. There are patients now in the medical wards who are regarded as candidates for the operation in the future, so that it is likely that I shall be able to report additional cases during the winter.

In my next letter I hope to be able to give some interesting facts in connection with the regular work of the semester, which begins on the 1st of October.

MEDICAL EDUCATION IN AMERICA AND IN GREAT
BRITAIN.

Some weeks ago, "A British Practitioner Resident in the
States" unburdened himself in the columns of the "Lancet"
on the subject of certain ameliorations of the status of American
graduates that it was thought would result from the operation
of the new British medical bill. He scarcely attempted to
disguise his horror at the reflection that the graduates of Ameri-
can medical schools were in the slightest degree likely to meet
with any sort of consideration in Great Britain. Somewhat
after the manner of the conventional British tourist, he pro-
ceeded to picture the low state of medical education in "the
States." Such a course is well known to be eminently soothing
to the English mind, and in this instance there can be little
doubt that the satisfaction gained by the writer was most de-
cided, for, besides freeing his mind, he was patted approvingly
on the back by the editor of the "Lancet," and, although his
depreciatory statements have been denied by various corre-
spondents of the same journal, and the utter lack of substantial
foundation for his inferences has been abundantly demonstrated,
he still banks in the sunshine of editorial favor.

So gross are his misrepresentations that "Another British
Practitioner Resident in the States" has felt impelled to con-
tradict them in the "Lancet," whereupon our contemporary is
moved to append this editorial note: "We can only say that,
if, as our correspondent asserts, 90 per cent. of the American
students can pass such an examination as the matriculation ex-
amination of the University of London, it is a pity they have
not the opportunity of doing so, both for their own sakes and
the reputation of American degrees, which can not be re-
pected abroad so long as the guarantees of preliminary edu-
cation are withheld and short curricula are the rule." In other
words, no American graduate can be "respected abroad" so
long as the greater number of the medical schools in this coun-
dry do not furnish the guarantees in question, no matter how
exacting may be the school from which he has received his
degree, or what may be his own attainments.

Strictly construed, to be sure, the "Lancet's" remarks
apply only to the degree, and not to its possessor, but the fact
remains that they include all American degrees, without any
attempt to discriminate between institutions of a high grade
and those in which the requirements are lax. Still, illogical as
such sweeping condemnation seems to be, it could in itself
scarcely lead to practical injustice, for, as we look at the mat-
ter, no degree is entitled to a great amount of respect, whether
it emanates from an American or from a European school.
Asses are to be found in every alma mater's brood.

The British are perfectly right in refusing to recognize an
American degree as a qualification for practice, and we are
unjust to ourselves in not declining to accord the same recog-
nition to an English degree. It seems only a question of time
when British practitioners "resident in the States" will be
practitioners only by virtue of an American examination. Per-
haps then they at least, if not their countrymen at home, will
be a trifle less given to reproaches of the sort alluded to.

A POINT IN THE PROGRESS OF THERAPEUTICS.

Whatever encouragement there may be to the medical pro-
fection in contemplating the steady decrease of the general
death rate of late years, the practical mastery attained over the
great pestilential diseases of bygone times, and the increasing
recognition accorded by the public to the earnestness and in-
telligent character of our efforts to prolong the average dura-
tion of human life, there are other considerations upon which,
although they may be less striking, physicians may found a just
sense of satisfaction with the practical working of their craft.
Not the least of these considerations is the reflection that the
practice of medicine tends constantly toward the greatest pos-
ible amelioration of the sufferings, and even the minor discom-
forts, that to some extent are still inseparable from the state of
sickness.

It is within the memory of those now in active life not only
that the course of medication thought necessary in their child-
hood was annoying, disturbing, and often even prostrating, but
that the restrictions put upon them in respect to their eating
and drinking, to say nothing of the other features of their
daily life, were in many instances harder to bear than the de-
rangements incident to the disease. The worst of it was, that
much of the harrowing ingenuity of the past was in no wise
mimical to the continued progress of the morbid condition from
bad to worse. Indeed, the man would be bold who should
affirm that it was not in many cases directly contributory to
such progress. It is not pleasant to reflect that in old times—
and not so very old—men were made miserable with the re-
sult of increasing their chances of speedy burial; and that this grim
fact was the most prominent fruit of centuries of devotion to
the study of the laws of health and disease. We may com-
fort ourselves with the thought that our fathers were led into
these errors by faulty methods that we have now abjured—
mainly by enslaving their observation at the behest of au-
thority.

Among the most gratifying features of the modern way of
managing disease is the consonance of attempts to make pa-
teins comfortable with the real agencies at work for their
restoration to health. A contributor to our last issue calls
attention to one of the more important of these attempts—the
free use of water in the dietary of young children. The argu-
ments presented by Dr. Remsen, and the facts that have led
him to bring them forward, are such as must command the
earnest attention of our readers. There are few restrictions,
whether in health or in disease, more vexatious than a limi-
tation set upon the amount of water one is at liberty to drink
—amounting often, in the case of infants, to a total prohibition. Since there seems good reason to suppose that this enforced deprivation is as damaging as it is annoying, and since there can be no question that those morbid conditions are very rare in which the unrestricted use of water is injurious, there can be no doubt that the hint given by our contributor will be borne in mind by many a practitioner who might otherwise have overlooked the matter for years.

THE PHYSICIANS' MUTUAL AID ASSOCIATION.

Dr. Rees, of Brooklyn, whose labors in behalf of the association have been so effective, spoke with wisdom when on a recent occasion, while advocating the enterprise before his fellow-members of the Medical Society of the County of Kings, he laid stress on the benevolent aspect of the association's work and refrained from recommending it as a cheap form of insurance. We have heretofore spoken of the matter in much the same strain, for it seems not only disingenuous toward those who contemplate membership, but really injurious to the prospects of the association, to represent it to be what it is not. Many an organization of like objects in so far as the insurance element is concerned has been wrecked on the shoals of disappointed expectations. To maintain that any voluntary society of the sort can compete in the matter of cheap insurance rates with the great corporations that make the business of life insurance a study is to assert what can not stand the test of investigation, and whoever becomes a member of such a body under the delusion in question is sure to become lukewarm if not discontented when the facts open his eyes.

The prosperous course of the association, to which we have taken pleasure in calling attention on several occasions, is doubtless due in great measure to the avoidance of the illusory pretensions alluded to. Its managers have been abundantly justified in setting forth certain advantages which do accrue to members, such as the promptness with which the amount due the family of a deceased member is forthcoming, but, so far as we have observed, they have never failed to put all the benefits of membership in their true light.

THE NEW MEDICAL COLLEGE IN BUFFALO.

In this age of the multiplication of medical colleges it is not often that an institution of the sort starts with so many praiseworthy features, and with so great an earnest of success, as the Medical Department of the University of Niagara. It is true that the idea seems to be entertained in some quarters that the legal formalities involved in its organization are defective, but of this we have seen no satisfactory evidence. The connection of the school with the university is probably closer and more real than is commonly the case in this country with medical schools that are ostensibly departments of universities; the parent institution seems to be on a firm financial basis; and the faculty of medicine must certainly be called a strong one on the whole.

We do not suppose that another college was at all a matter of necessity to Buffalo, but that is a consideration that may properly be urged in the case of many other cities. Competition would doubtless stimulate to the highest order of medical teaching in the United States, were it not allowed to degenerate into a race between a great many colleges as to which of them can so level the rugged paths of learning, and in every way so facilitate the transition from the plow-boy to the doctor, as to lure the greatest number to its arms. Since, with practically very few exceptions, the degree granted by one college is as good as that from any other in the eyes of the law, and, for that matter, before the community, and since almost any coterie of physicians may effect an organization that shall constitute them a medical college empowered to grant the degree, there is little hope that competition will accomplish any more good than that of raising the quality of the training that is to be had by the few who are resolved to get the best attainable education. Until some other ordeal is imposed than college examinations as the test for admission to the profession, it is useless to expect any marked change in this state of things. But this very fact makes it all the more a matter of congratulation when a new college aims not so much to win students as to deserve a good repute; and, from all we can ascertain about the new college in Buffalo, such is the course upon which it seems to be entering. From the character of its faculty, and from the tenacity of purpose usually manifested by institutions governed as the university is governed, we do not doubt that the Medical Department of the University of Niagara will take a high stand among our medical colleges.

MINOR PARAGRAPHS.

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

The President of the society, Dr. Alexander Hutchins, of Brooklyn, has issued a circular in which he very properly calls attention to the fact that the Business Committee, not being appointed until the opening of the meeting, can not be expected to charge itself with more than arranging the order of business for the time being. He therefore asks the personal co-operation of the delegates and members in providing papers for the meeting, and requests that the titles of the same, with the authors' names and addresses, be forwarded to him as early as practicable. A general compliance with the President's requests ought certainly to be made, and, if that is done, we may look for a meeting of unusual interest.

THE HEALTH OF CONNECTICUT.

By a late report from the Secretary of the Connecticut State Board of Health, it appears that zymotic diseases were quite prevalent during the month of August, causing a mortality amounting in some instances to nearly fifty per cent. of the entire mortality. Particular attention is called to the prevalence of typhoid fever, and it is stated that diphteria shows no abatement in Hartford.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 2, 1883:
LETTERS TO THE EDITOR.

[N. Y. Med. Jour.,

DISEASES. &dquo; Cases. Deaths. &dquo; Cases. Deaths. 

TYPHOID FEVER &dquo; 84 12 86 11 
SCARLET FEVER &dquo; 29 2 26 8 
CEREBRO-SPINAL MENINGITIS &dquo; 3 5 2 3 
MEASLES &dquo; 4 2 11 4 
DIPHTHERIA &dquo; 17 12 41 16 

MALIGNANT SMALL-POX IN MEXICO.—Information was received on the 1st inst., by the Surgeon-General of the Marine-Hospital Service, that malignant small-pox was raging in Tepacheula, State of Chiapas, Mexico. Twelve hundred deaths had already been reported. The town has a population of about ten thousand.

THE INFECTIOUS DISEASES OF CATTLE.—On the 15th and 16th of November a conference of persons interested in the matter will be held in Chicago, to consider the extent of prevalence of these diseases in America and the best means of preventing them.

THE FOOT AND MOUTH DISEASE is said to be prevailing to an alarming extent in many of the counties of England.

THE FRENCH CHOLERA COMMISSION.—We regret to learn that one of the members of M. Pasteur's commission, Dr. Thuillier, has fallen a victim to the disease.

THE PHILADELPHIA HOSPITAL.—On Tuesday the medical staff adopted the following:

Whereas, There exists in the Philadelphia Hospital a great and imperative need for wards specially planned and constructed for the care of lying-in women; therefore,

Resolved, That the medical staff of the Philadelphia Hospital do most respectfully and most urgently request the Select and Common Councils of the City of Philadelphia by enactment promptly to authorize the Guardians of the Poor to construct without delay the Maternity Pavilions, as has been recommended by the Board of Guardians of the Poor to the Finance Committee of the City Councils.

AN ALLEGED NOISE AT GLEN COVE, a starch and glucose factory, was lately inspected by a committee of the State Board of Health. The singular statement is made that 234 citizens had petitioned for the abatement of the nuisance alleged to be due to the operation of the factory, while 518 presented a counter-memorial asking that no notice should be taken of the petition.

THE COLLEGE OF PHYSICIANS AND SURGEONS.—The winter session was opened on Monday evening by an introductory address by Dr. George H. Fox, Clinical Professor of Diseases of the Skin.

THE MONMOUTH COUNTY, N. J., MEDICAL SOCIETY.—We learn that the following-named gentlemen were elected officers at a meeting held at Freehold on Monday: Dr. Edward Field, of Red Bank, president; Dr. C. D. W. Vandyke, of Perrineville, vice-president; Dr. D. M. Forman, of Freehold, secretary; and Dr. I. S. Long, of Freehold, treasurer.

THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.—It is announced that Mr. John P. Howard intends to give an additional sum of money to the university, part of which is to be devoted to a new building for the Medical Department.

GUY'S HOSPITAL, LONDON.—A refreshment-room has lately been established for the students' convenience. A like action on the part of our own colleges would undoubtedly prove of great benefit.

THE AMERICAN ACADEMY OF MEDICINE will meet at the New York Academy of Medicine on Tuesday, October 9th (three o'clock), and Wednesday, October 10th. The address by the President, Dr. H. O. Marcy, of Boston, will be delivered on Tuesday evening, October 9th, at eight o'clock, on "The Recent Advances of Sanitary Science; the Relations of Micro-organisms to Disease" (illustrated by micro-photographs projected upon the screen). The following papers have been promised for the general meetings: Dr. L. S. Filcher, of Brooklyn, N. Y., "On the Relations of Medical Journalism to Higher Medical Education in America." Dr. Trulli Green, of Easton, Pa., "On the Imperfection of Technical Studies as a Means of Mental Culture." Dr. Benjamin Lee, of Philadelphia, "On the Value of an Acquaintance with Botany as a Preliminary to the Study of Medicine." Dr. Charles McIntire, of Easton, Pa., "Is it Fair? The Study of the Comparative Political Position of the Medical Profession in the United States." Dr. A. D. Rockwell, of New York, on "The Exact Value of the Electrolytic Method," Dr. J. Cheston Morris, of Philadelphia, "The Milk Supply in Large Cities." Dr. Charles E. Cadwalader, of Philadelphia, "Considerations upon the Public Provisions for the Care of the Indigent Insane." Dr. A. D. Rockwell, of New York, "The late Dr. George M. Beard—a Sketch." Report of the Committee on Laws of Medical Practice in the United States and Canada (Dr. Dunglison and Dr. Marcy).

OBITUARY NOTES.

JAMES A. FLEMING, M. D., OF BOSTON.—Dr. Fleming died in the Massachusetts General Hospital on Sunday last of typhoid fever contracted while on duty at the State musing. He graduated from Harvard Medical School in 1876, and was for over a year connected with the medical staff of the Boston City Hospital. He was surgeon of the Ninth Regiment of Volunteer Militia at the time of his death.

PROFESSOR COLONICATTI, OF TERN.,—Dr. Vittorio Colonicattii, professor of pathological anatomy in the University of Turin, died recently, at the age of thirty-five.

Letters to the Editor.

THE PROPOSED AMENDMENTS TO THE CONSTITUTION AND BY-LAWS OF THE ACADEMY OF MEDICINE.

To the Editor of the New York Medical Journal:

Sir: I have received a printed postal circular, apparently signed with some of the most distinguished and honored names of the profession in this city.

I know not how generally this circular has been sent to the Fellows of the Academy, as I have seen but one other copy, but, as it refers to a circular which I have sent to every Fellow, I deem it necessary to say that I think it bears evidence on the face of it that it is a sily, not to say a cruel hoax. I will give my reasons for this belief, which, I think, are conclusive:

1. When introducing the resolutions which have caused all the disturbances in the Academy of Medicine, the gentleman who moved them "deprecates the admission of any Fellow who could not cordially support the code of ethics of the American Medical Association." The resolution instructed "the Committee on Admissions to report to the Academy for election as Resident Fellow no physician who is known by the committee to be in opposition to this code of ethics," and these resolutions were "to continue in force until the American Medical Association shall have modified or repealed its code of ethics."

Afterward the same gentleman who moved the resolution stated: "The movement which many of us have gone into is to sustain the code of ethics of the American Medical Association."
The assertion, therefore, in the postal circular, that "the code has never been made a subject of discussion in the Academy by any in favor of upholding it," is exactly the opposite of the fact. It was really the gravemen of the whole discussion that memorable evening.

The higher the standing of men, the less they can afford to have their names appended to an intentionally misleading statement which the whole profession in this city and in this State know to be erroneous. I can have no doubt that many of those whose names appear on this circular will make haste to correct the error, and "rise to explain" by avowing, either that they never signed this paper, or that they did so hastily without reading it.

2. This postal circular asserts: "The resolutions presented and adopted at the last meeting of the Academy had for their object (the italics are mine) the prevention of any future discussion relating to the code."

This was the object of a resolution introduced one year before by Dr. Austin Flint, Sr., which was unanimously carried, and successfully accomplished its purpose until the resolutions of the last meeting of the Academy were introduced.

3. As those whose names appear on this postal circular are men of the highest intelligence and education, they never could have consciously signed a statement that the Academy "owes its origin" to "its time-honored constitution and by-laws," as, in the belief of most, this statement also is the opposite of the fact. It is generally supposed that the origin of the constitution and by-laws was in the Academy.

Yours truly,

Fordyce Barker.

October 3, 1883.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

A stated meeting was held October 4, 1883, the President, Fordyce Barker, M.D., LL.D., in the chair.

[Before the meeting, the following circular had been sent to the Fellows by the President:

The President's Circular.—"I assume that every Fellow of the New York Academy of Medicine must regard it as a most unfortunate event that anything should occur to interrupt its fraternal harmony, its useful work, and its progressive growth. While we can not shut our eyes to the fact that this is the present condition of the Academy, it would be both useless and unwise to discuss the causes which have brought about this state of things, because, from their nature, they involve questions on which the most able, the most loyal, and the most conscientious men in the profession honestly differ. Let us accept this fact as inevitable, and that the Academy can do nothing which will effectively advance the interests of the profession by way of discussions, which irritate, but do not change convictions, or by arbitrary regulations, secured by shrewd tactics, but which carry no moral force.

"The Academy of Medicine is not fulfilling its mission when it is engaged in warm discussions of questions of casuistry, in polemical controversies, or in medical politics.

"The 'Ephemera' of Dr. Squibb quotes with approval an editorial from the 'Boston Medical and Surgical Journal,' which contains the following sentence: 'The lesson also is so obvious that he who runs may read, that the more our societies confine themselves to their proper field—the joint cultivation of medical science and good fellowship—and the less they meddle with medical politics, the better will it be for their own future and the common good of the profession."

"It seems to me that the truth of the foregoing sentiment has been unfortunately, but clearly, demonstrated by our Academy of Medicine."

"The question which we have now to meet is: What measures can be taken to secure for the Academy a return of its prosperity? by which I mean a restoration of its fraternal harmony and good fellowship; a renewal of its active scientific work; an increase of its funds for the growth of its library and the adequate support of its journal department.

"Since our last meeting this question must have occupied the minds of all our Fellows who appreciate the importance of the Academy, which should represent the highest scientific work of the profession of this city. All must feel that the character of the profession and the grade of individual reputation are deeply involved in a wise settlement of this question.

"I trust that no one will suspect me of a wish to force my individual views upon the Academy, but that, in consideration of the experience which I have had in its affairs, each will understand the spirit in which I venture to offer a few suggestions to be discussed, amended, or improved, at our first meeting in October. I do not feel it necessary to apologize for expressing the hope and the belief that every Fellow of the Academy who feels a 'proper sense of his personal responsibility, and what he owes to the profession and the public, will be present, and contribute by his voice or his vote to a satisfactory adjustment of our present difficulties."

"It must be obvious to all that to attain this end we must make a new departure on certain questions, to which it is unnecessary to refer more definitely. There is an 'irrepressible conflict' of views and opinions which can not be settled by parliamentary tactics or a majority of votes, but must continue until in the progress of time the moral sentiment of the profession is crystallized in a public opinion which will have the force of law. No possible good can come from profitless and irritating discussions of these questions in the Academy of Medicine. It therefore seems to me of vital importance that, now, in making a new departure, everything in relation to them should be buried in the past and forgotten. No unhappy differences can be settled, no principle or cause can be advanced, no society or individual can be benefited, by keeping up a galling wakefulness, and feeding the living ulcer of a corroding memory of the past. The amodyne draught of oblivion is the first specific remedy for healing such ills as those under which the Academy is now suffering.

"The next point to be secured is such a change in our organic laws as to make it impossible that trouble and danger can ever occur again in the Academy.

"At our first meeting in October, certain amendments to the Constitution and By-laws will be proposed for discussion, and at the following meeting they will be submitted to the vote of the Academy.

"Every change proposed has been the result of a most careful study of the subject, and has a distinct purpose, which will be obvious to all.

"I think it will be apparent that the whole intent of the proposed amendments is to make the Academy of Medicine a purely scientific society, independent of all other organizations: to place its standard of ethics on a higher plane than before; and to prevent the possibility of any future troubles by the introduction of matters foreign to its avowed objects."

Subsequently the Council of the Organization for upholding the National Code of Medical Ethics in the State of New York sent out the following circular:
by Dr. Edward L. Keyes, and seconded by Dr. Alfred L. Loomis:

CONSTITUTION.—Article VI, Section I.—Strike out: 2, A Committee on Medical Ethics; 3, A Committee on Medical Education.

Read: 1, A Committee on Admissions; 2, A Committee on Library.

[At present the clause in question reads: "1. A Committee on Admissions. 2. A Committee on Medical Ethics. 3. A Committee on Medical Education. 4. A Committee on Library."]

Article VIII.—Strike out the whole as it now stands.

Read: The Academy reserves the right of discipline by admonition, suspension, or expulsion, by which all rights and privileges as a Fellow are forfeit, for violation of its By-laws or Regulations, for unprofessional, ungentlemanly, or dishonorable conduct, and for public immorality and great crimes.

[The Article now reads: "The Academy reserves the right of punishing violations of its Regulations, or of its code of Medical Ethics, by reprimand, suspension, or expulsion, and will recognize no Fellow as a regular practitioner who has been expelled."]

BY-LAWS.—By-law X.—Strike out third paragraph in third sentence. Also strike out last sentence, for which read: Five members of the Council shall constitute a quorum for its ordinary meetings, but a majority of the Council shall be necessary for a quorum at its annual meeting in December, and at special meetings called by the President.

Add to By-law X, as follows:

SECTION 2. The Council, specially convened by the President for the purpose, shall have the power to inquire into any alleged infringement of the By-laws or misconduct by any Fellow of the Academy, on a written charge, signed by three Resident Fellows; and the Fellow whose conduct is in question shall be invited to attend. If, after investigation, the charges are sustained by a majority vote of those present, the Council may determine by a majority vote whether the punishment shall be a private admonition or a public reprimand by the President at a meeting of the Academy (whether the offender be present or absent), or suspension for a definite period.

But in case the charge is of so grave a character that the Council, by a vote of two thirds of those present, consider that the offender should be expelled, the report of the Council and its recommendations shall be referred to the Academy, of which due notice shall be given to every Resident Fellow four weeks previous to its final action. The vote shall be taken by ballot, and two thirds of those cast shall be necessary to sustain the vote of expulsion.

[The By-law now reads: "The Council shall supervise the general affairs and interests of the Academy; they shall provide suitable accommodations for its meetings, for its movable property, and for its business transactions; they shall estimate for the annual assessment, when at any time an increase thereof may be necessary; they shall annually, in December, audit the financial accounts, and oftener if deemed requisite; they shall authenticate and authorize the payment of all bills against the Academy not exceeding fifty dollars; they shall confer with the Trustees, the Treasurer, the other officers, and with the standing committees through the chairman of each, in reference to their respective functions and business relations; they shall appoint the Librarian, the Assistant and Statistical Secretaries; they shall nominate such Fellows as are to be appointed to deliver series of discourses or lectures on scientific subjects before the Academy, and also a Fellow to deliver the Anniversary Discourse; they shall determine the propriety of the reading of any paper offered by any person not a Fellow of the Academy; they shall select and recommend to the Academy for publication from the archives such essays, memoirs, or reports, as are to appear in the printed Transactions. All papers published in the Transactions shall be by a two thirds vote of the members present.

The National Code Circular.—The Council of the Organization for upholding the National Code of Medical Ethics in the State of New York begs to call your attention to a circular recently issued in which are proposed certain amendments to the Constitution and By-laws of the New York Academy of Medicine. The Council can not but regret the issuing of this circular as a covert movement, under a plea for harmony, in behalf of the organized effort in opposition to the National Code of Ethics. The proposed amendments, were they adopted, would eliminate from the Constitution and By-laws everything relating to ethics, and surrender the Academy to those who advocate the abolition of all ethical codes. The Academy would thereby be deprived of the right of representation in the American Medical Association, and of affiliation with other medical organizations out of the State of New York.

It may be assumed that there is no disposition, on the part of those who are for upholding the National Code of Ethics, to raise any discussion respecting the code in the Academy. The code has never been made a subject of discussion in the Academy by any one in favor of upholding it, and there is no ground for the supposition that it ever will be, unless it becomes necessary in the way of defense. The resolutions presented and adopted at the last meeting of the Academy had for their object the prevention of any future discussion relating to the code.

Every true friend of the Academy is earnestly requested to attend its meetings in order to resist the introduction of discussions and controversies in relation to ethics, by simply maintaining, in their integrity, the time-honored Constitution and By-laws of this institution, to which it owes its origin and prosperity.

They shall fix the prices of all publications offered for sale; they shall, by a two-thirds vote, fill all vacancies until the next annual election except of the President, Vice-Presidents, and the Trustee, which shall be filled by the Academy; they shall appoint all delegates to other societies when admissible; they shall supervise the printing and publication of all papers and volumes ordered by the Academy; and they shall once a year report in full to the Academy. A majority of the Council shall be necessary to constitute a quorum.”

By-law XIII.—Strike out Section 8 as it now stands, and read as follows:

Section 3. The Committee on Admissions, upon receiving from the Recording Secretary the names of the candidates proposed for Fellowship, with their professional credentials, shall make due inquiry concerning them as regards their personal character, their standing in the profession, and their eligibility as persons of honor, who do not assume peculiar designations, implying special modes of treatment.

Add to By-law XIII, Sections 4 and 5, as follows:

Section 4. The Committee shall report within three months, such as may be deemed worthy of admission, and, if for Resident Fellowship, the report shall specify the source whence the nominee derived their diploma or license to practice, with the dates thereof.

Section 5. If this Committee fail to report within the time specified upon any nomination submitted to them, any Fellow of the Academy may renew such a nomination; and, if this be seconded, a vote shall be taken, it being distinctly stated that the nomination has not been approved by the Committee on Admissions.

By-law XIII now reads: “Section 1. Each candidate for Resident Fellowship must be proposed in writing by three Fellows personally acquainted with him, and may be admitted at a meeting subsequent to his recommendation by the Committee. The recommendation of Corresponding, Honorary, and Non-Resident Fellowships from the Army and Navy must be at least one month before the Academy before the candidate can be admitted.

“Section 2. Admissions to Fellowship must be by a three-fourths vote of the members present at a stated meeting.

“Section 3. The Committee on Admissions, upon receiving from the Recording Secretary the names of the candidates proposed for Fellowship, with their professional credentials, shall make due inquiry concerning them, and all information thus obtained shall be confidential; they shall report within three months such as may be deemed worthy of admission, which report, if for Resident Fellowship, shall specify the source whence the nominee derived their diploma or license to practice, with the dates thereof; and should this committee fail to report within the time specified upon any nomination submitted to them, any Fellow having made such a nomination may renew the same directly to the Academy, and a vote shall be taken upon it; in this case, however, the affirmative vote of four fifths of the Fellows present, as ascertained by ballot, shall be requisite to insure an admission; and, on the question being put, it shall be distinctly stated that the nomination has not been approved by the Committee.”

Strike out By-laws XIV and XV; the subsequent By-laws to be numbered XIV, consecutively, to XXIV.

By-law XIV now reads: “Section 1. The Committee on Medical Ethics shall hear all complaints of violation of medical ethics on the part of any Fellow, and decide all questions of medical ethics submitted to them by the Academy. They shall also notify to appear before them any Fellow of the Academy against whom any charge may have been preferred, and furnish him with a copy of the same; his appearance being also cited to appear, the committee shall proceed to take testimony and hear the defense, reserving their decision to be reported to the Academy at the next stated meeting, when their action may be affirmed by a majority of the Fellows present; but the vote of three fourths shall be required to reverse the decision of the Committee.

“Section 2. Every charge against a Fellow of the Academy shall be made by a Fellow, and addressed to the Recording Secretary, under a sealed cover, with the words ‘Charge against a Fellow’ written upon it. The receipt of such paper shall be announced to the Academy by the Secretary, who, after designating it by a number, shall hand the same over to the Committee on Medical Ethics.

“Section 3. It shall be deemed a chargeable offense to countenance, encourage, or patronize—by advertising, giving certificates, or in any other way whatsoever—an irregular practitioner, or the proprietor or vendor of any nostrum, patent, or quack medicine; or to commit any act which unfavourably affects the character of the Medical Profession.

“Section 4. A three-fourths vote of the Fellows present shall be necessary to expel a member.

“Section 5. All questions of Ethics in other respects shall, as far as applicable, be adjudged in accordance with the Code of Ethics promulgated by the American Medical Association and adopted by the Academy.”

By-law XV reads: “The Committee on Medical Education shall have cognizance of the systems of medical instruction, private and public, in this city and State, as compared with such as are elsewhere in use. They shall recommend such improvements in office training and office examinations, in text-books, in reading and in practical studies proper for the student, and in the public courses, theoretical and practical, at the colleges and hospitals, as may seem to them in keeping with the advances of medical knowledge and the exigencies of the profession. They shall notice any evasion or infringement of the laws of this State that may come to their knowledge in reference to the granting of degrees. They shall make, in other respects, such suggestions as seem to them worthy of attention for rendering our system of medical education thorough, efficient, and satisfactory. They shall report at least once a year to the Academy.”

By-law XXVI (new number as amended, XXIV)—

Add: And all resolutions, except such as relate to its formal routine business, must be offered in writing at the meeting two weeks previous to the final action, and printed on the notice of such final action.

By-law XXVI now stands: “These By-laws may be suspended by a three-fourths vote at a stated meeting. They may be repealed or amended by a similar vote, provided notice of the same has been given in writing at a previous stated meeting.”

In presenting these proposed amendments, Dr. Keyes remarked that he had been asked to do so by the President, and that he did so willingly, not only as a recognition of the great services the President had rendered the Academy, but also because he saw in their adoption an easy solution of the difficulties with which the Academy was now surrounded, which difficulties would otherwise inevitably continue. He had always striven to live up to the old code, he was not a new code man, he had positively declined to join either party to the controversy now going on. It was therefore not in the interest of any faction, but wholly for the sake of peace, that he now offered the proposed amendments and moved their adoption as a whole. [Cheers.]

Dr. Austin Flint, Jr., moved that the amendments take the usual course, and expressed the opinion that discussion on them at the present time was unseasoned for.

Dr. Alfred L. Loomis seconded the amendments introduced by Dr. Keyes, and said that he did so gladly, for he was fully convinced that by their adoption the greatest danger that had ever threatened the Academy would be averted, and we should ever after be freed from such occurrences as had taken place at the last meeting. For the Academy to maintain its prosperity and its prestige, all matters of ethics and medical politics must
be removed from it. [Cheers, at which the President requested that no more such demonstrations be made.] There were societies before which such matters properly came, but this was not one of them. The Academy was for scientific work and good fellowship, without fear of sharp tactics or bitter words. If the proposed amendments were carried, it would be impossible for any further disturbance of harmony to take place.

Dr. Flint, Jr., disclaimed any desire to delay or obstruct the business of the meeting, but again urged that the amendments could not be acted upon to-night and ought not to be discussed. He renewed his motion, and it was now seconded.

Dr. M. H. Henry spoke in support of Dr. Flint, Jr.'s, motion, and begged to remind the Academy that about a year and a half ago Dr. Loomis had not seemed to stand in such dread of bringing politics into the Academy, for he had then come here and spoken in the interest of the County Democracy, the matter of street-cleaning being made the pretext. Dr. Loomis was then the chief orator, but now he was dreadfully afraid of politics. For his part, he (Dr. Henry) had had enough of these elaborately prepared orations by "stars." [Dr. Hcnry was repeatedly called to order during his remarks, and toward their conclusion hisses were heard.]

Dr. C. C. Lee moved, as an amendment to Dr. Flint, Jr.'s, motion, that the meeting resolve itself into a committee of the whole, for the purpose of discussing the amendments. Seconded.

Dr. Flint, Jr., protested that his motion could not be amended.

The President decided that Dr. Lee's amendment was in order. It was put, and declared carried. A division having been called for, the amendment was found to have been carried by a vote of 135 to 15.

The President then appointed Dr. Ellsworth Eliot chairman of the committee of the whole.

In Committee of the Whole.—The Chairman appointed Dr. W. M. Carpenter secretary of the committee of the whole.

By request, the proposed amendments to the constitution and by-laws were then read by the Secretary. Dr. Louis Elsberg moved that when the committee rise it report to the Academy in favor of the proposed amendments as a whole. Seconded by Dr. C. F. Taylor. [Calls for question.]

Dr. B. B. St. John Rooma thought fairness required that the President should have a chance to be heard as to his reasons for proposing the amendment.

The President had not intended to take part in the discussion on the amendments, but was anxious to hear any objections to them that might be raised in a full and fair discussion. Since the request had been made, however, he could not hesitate. He repeated his gratification at Dr. Flint, Sr.'s, remarks. When, after the recent action of the State society, it was feared that its action on the ethical question would be brought into the Academy, Dr. Flint, this renowned physician whose fame was known wherever medicine was cultivated—this man whom he could not think of except reverently—had introduced a resolution to postpone the matter indefinitely. The resolution was carried unanimously, and had worked most successfully, until the action taken last spring, which had entirely changed the aspect of matters, and was, he thought, most injurious, imperiling the prosperity and usefulness of the Academy, inasmuch as it made two parties, the contention of which would keep out new members. He had, therefore, set about devising measures to undo the injury thus inflicted, and to guard against the possibility of further mischief of the sort. Without consulting anybody, but, as the result of a careful study of similar large societies in Europe that were free from such dangers, including the Royal Society, the French Academy of Medicine, the British Medical Association, and various others, he had devised these proposed amendments to the constitution and by-laws. He did not believe that any one present would accuse him of any but the best motives. [Applause.] He had supposed that many of the prominent and honored men in the Academy, even among those who were in favor of upholding the old code, would join in supporting the measures which he had devised; but in this he had been somehow disappointed. He had hoped that those gentlemen would see that the amendments were not in the interests of any ethical faction, but intended solely to promote the welfare of the Academy. He deprecated the distinction that had lately been made between the general principles of ethics and the code of ethics. [Dr. Barker then gave his particular reasons for each amendment. The chief points were that the Council was adequate to take care of the ethics of the Academy; that the Committee on Education had no function and no jurisdiction; that there should be one society free from all allegiance to other bodies, which allegiance had been made and argument in favor of the action taken last spring. The amendments would not violate the Academy's representation in the State Medical Society, for the present delegates remained members of the latter society until their terms expired; moreover, delegates would still be able to serve their local duties. As to the reduction of the quorum necessary in meetings of the Council, his object in recommending it was simply convenience, as it had often been found extremely difficult to assemble a quorum for the transaction of routine business. It would not, as had been feared, enable a few men to dispose of the Academy's property, for this could only be done by the Academy at large.]

Dr. Flint, Jr., thought that every one present knew, before the President's explanation, precisely what the amendments implied—they struck out the code of ethics, and the other amendments had had to be made to correspond. The report of this Committee of the Whole would amount to nothing. It was simply impossible for the amendments to obtain a three-fourths vote at the next meeting. Therefore their introduction could only act as a firebrand. Discussion was wholly unnecessary, and he and those who thought with him would not take part in it.

The President moved to amend Dr. Elsberg's motion as follows: Resolved, That in the opinion of the Committee of the Whole it is advisable that the amendments to the constitution and by-laws proposed this evening be adopted as a whole, and that the chairman be so instructed to report. He also gave notice that he would subsequently move that, when the committee rose, it should report progress, and ask leave to sit again on the 18th of October.

[A motion to rise having been made and seconded, it was put and declared lost.]

The President again brought up his motion instructing the committee, and it was now seconded and declared carried. A division having been called for, the motion was found to have been carried by a vote of 109 to 94.

On motion of Dr. Flint, Jr., the committee rose, reported progress, and asked leave to sit again October 18th.

On motion of Dr. H. C. Pafford, the committee's request was granted.

The President then took the chair.

Dr. Flint, Jr., moved that the amendments lie over until the next meeting, under the rules. Carried.

The meeting then adjourned.
Dietetics for the Sick.—Dr. Charles M. Seltzer read the following paper:

In presenting this paper, it is but justice to state that it has been prepared during the leisure of the past week as a substitute for one by another member, who was unable to keep his engagement. The subject has been selected more from the hope of eliciting some practical ideas, and a desire to emphasize its importance, than to announce anything new, or to exhibit the best pieces of a hobby. Close attention to the methods of our most successful general practitioners convinced me that in dietetics was their stronghold. At the same time there was plainly to be seen a distressing lack of knowledge as to variety of foods and the preparation of them. In order to find out whether there was a practical remedy for these two great faults, I have gone over a thorough course of preparation of diet for the sick, under the instructions and guidance of Mrs. S. T. Rorer, in whom are combined the practical attributes of cook, chemist, physiologist, and nurse, and I can safely say that, if every member of this society were to do likewise, his armamentarium, success, and self-satisfaction in the practice of medicine would be increased many fold.

It would be almost an endless task to discuss the literature of this subject. Let us condense the opinions of physiologists, chemists, hygienists, and all others in authority, by stating that food is divided into nitrogenous or albuminuous; hydro-carbons or starch, sugar, and fats; and mineral or the various salts of the alkalies. Of these, the nitrogenous and minerals are the building materials, and the hydro-carbons are the heat- and force-producers. Food may also be classified into liquid, semi-solid, and solid; and, as the sum total of digestion is a matter of absorption and assimilation, it follows that the more liquid or dissolvable food is, the more readily will it be absorbed; hence this is the form to be chosen when it is desirable to obtain nourishment at the least possible expense of organic action. There are also conditions in which bulk and solidity are necessary, and here we select the semi-solid or solid food, or even indigestible matter.

Nitrogenous food, in its natural combination with mineral matters, is mostly made absorbable by stomachic digestion; it rebuilds the tissues, and the waste and refuse are excreted by the kidneys and skin as urea and uric acid and its salts.

Hydro-carbons are digested in the mouth and small intestines, are burnt up by union with the respiring oxygen, thus supplying heat and force to the body. The waste and refuse are excreted by the lungs and bowels.

About three ounces of nitrogenous and twenty ounces of carbonaceous food are necessary to sustain the life of an adult man in idleness. With these epitomized facts in mind, let us consider the importance and use of dietetics in the treatment of disease. The importance has been signalized by Bence Jones, who has said that the effect of diet is far beyond any known remedy. This fact has been so well known for the past century that volume after volume has been written on "Dietetics," "Diet Cures," etc. A few of these have become standard works of authority, because of their scientific and exhaustive treatment of the subject, while hundreds of others have had but an ephemeral existence. All have had to reiterate the same facts, because very few new ones have been learned, and, aside from the knowledge of artificially digested food, the student of a hundred years ago knew as well as the student of to-day about what diet was necessary for the sick. True, theirs was an empirical teaching; they knew nothing of the physiological actions of diastase, pepsin, and pancreatin, but they wore all the more practical for that. Our present scientific reasonings on digestion are but the formation of rules and theories for very old facts. The importance of the subject is made more manifest when we consider how much of the sickness that we are called upon to treat is the result of some error in eating or drinking, and, as "removal of the cause" is the first step toward the promotion of recovery, it is easy to perceive how essential it is to know what constitutes proper and improper diet. Life depends upon diet, and the restoration of health depends upon the same principles as its preservation. Disease is the result of the violation of the laws of health, hence the first step toward recovery is to re-establish those laws; and as the material for repair and support must come from diet, we, as thorough physicians, should have a complete practical knowledge of dietetics and a proper appreciation of their curative value. But almost a decade of experience among physicians compels me to acknowledge that this is not the case, and that the most lamentable deficiency is in the practical application of the subject. Nature's simple and easily understood remedies are either lost sight of or ignored in the blind endeavor to find a medical specific for every human ill, or to establish an ideal notion, theory, or pathy. For the treatment of chronic affections, some good points may occasionally be gained by even observing the modus operandi of quacks, homoeoquacks, and proprietary medicines, for in connection with either a depurative or impure preparation such dietetic and hygienic directions are almost invariably insisted upon as would, in themselves, relieve temporarily, and perhaps permanently, some of the most obstinate cases.

The methods of dietetic treatment of diseases are as various as are the ills that flesh is heir to, but all of them contain some of the following principles as essential features. In acute diseases, rest is of primary importance; it is the fundamental principle of their medical and surgical treatment, and the same idea must be carried out in dietetics by remembering what part each organ serves in absorption, assimilation, and excretion, and by avoiding such food as would cause the performance of that function. Of course, this plan is only to be pursued while the disease is advancing, and as soon as recovery begins there must be a gradual return to a promiscuous diet; very little at first—just enough to slightly exercise the crippled organ, using as great care as we would in instituting passive motion in a limb that has been fractured. Nature enforces this principle by the loss of appetite that marks the onset of nearly all acute diseases. The dietetic rest of an organ does not necessarily imply a depleitory diet, for, while it is non-active, other organs may be made to perform a compensatory amount of work, and thus sustain or even increase the patient's vitality—so great is the versatility of our organic functions. It is upon this idea that we must act when we obey the command of Graves to feed fevers. In chronic diseases—those in which the natural course is direct from bad to worse, until death or some interfering process puts an end to them—every organ must be made to do its utmost; the whole system must be awakened to the threatening destruction. Herein lies the broadest field of action for our subject. No time should be lost; food should be administered as frequently as assimilation and proper amount of organic rest will allow; the appetite should be kept active, by using liquid, semi-solid, and solid food, prepared in such a variety of ways as to allow no charge of monotony or disgust. Surprise is frequently a useful element. Instead of leaving the patient to select out of his or her likes and dislikes, the nurse should be privately instructed how and what to prepare for each time, and how to serve it in the most appetizing manner. A valuable aid, usually lost sight of, is compliment. Think but for a moment how a savory dish will sharpen our appetites while in health, and I
an sure you will perceive its stimulating influence upon a de-
bilitated patient, to whom the flat and insipid preparations usu-
ally offered are loathsome, or even nauseating. This disgust
might frequently be avoided, and the amount of prescribed
medicine be lessened. Many of the bitter tonics and carma-
tives of our materia medica are the same as are used in cookery,
and are none the less efficacious in a palatable dish than in the
nauseous pill or draught. Therefore let the delicate aroma of
herbs, celery, and bay-leaves pervade the soups; use India
curry on starchy foods, and, when desirable, add capsiicum,
Piper nigrum, etc., to animal broths and substances. In so
doing, if necessary, you can satisfy the qualms of your profes-
sional dignity by remembering that in catering to the palate
you really safeguard the organs of digestion.

Some articles of diet may be administered simply for their
curative effect. A five-ounce cup of strong coffee contains
about sixty-six grains of extract, or an equivalent of about two
grains of caffeine—quite sufficient to relieve a neuralgia, or
a headache and sick stomach after a dose of opium. Beef-tea,
made red-hot with red pepper, is the very best treatment for
delirium tremens. A patient to whom I once administered such
a dose, made so strong that I would not have dared to taste it
myself, afterward told me that it was the most refreshing and
cooling drink he had ever taken. A London surgeon to the
police told me that he had treated a hundred and fifty cases of
delirium tremens with this remedy alone, and had not lost one.
The use of chloral in these cases is criminal, and many a death
certificate of "delirium tremens" ought to be "heart failure
from chloral poisoning." Mucilaginous teas and drinks made
from gelatin, isinglass, Irish moss, and flaxseed, are very soothing
to any inflammation within the digestive tract. Green vegeta-
tables are necessary to cure as well as prevent scurvy.

An old practitioner, who had spent his early professional
life in the country, told me that when he first commenced prac-
ticing he used all the ordinary remedies in typhoid fever with-
out any satisfactory results, until the introduction of turpen-
tine by the late Professor George B. Wood. In it he soon
discovered a useful ally, not so much in the drug per se, but
because convenience and time compelled him to use a thick flour
gruel as a vehicle, and the patients were nourished sufficiently
to live through the attack.

In the science and art of preparing sick diet there is a most
lamentable lack of knowledge, especially among physicians.
They know the preparations by name, but not by nature, and
the only way to learn the latter is to don the apron and take a
practical course from a practical and scientific cook. Such a
course was inaugurated last winter in this city and in Boston,
with a very satisfactory result. The prospect for this season in
this city is that the course will be very well attended. It is the
only way to learn. I could read you receipts by the score, but
it would be as useless as reading off so many medical formulae.

Dr. L. T. Burnell, in opening the discussion, said: In refer-
ce to these questions, my opinions are rather of the old-
fashioned kind, and I believe in courses of instruction on cook-
ing, which will be of much use to physicians. Dr. Benjamin
Rush was accustomed in his lectures to remark that "a physician
should spend six months in a kitchen before entering upon his
practical career." He desired to heighten the importance of a
knowledge of the effects of food, and also the correct way of
preparing it. All these advantages could be combined with a
course on pharmacy. Physicians should learn how to make
beef-tea, extract, etc., and similar articles. The important pre-
parations of mush, of Indian and oat-meal, for instance, are
rarely properly made. They should be prepared over night, so
as to be thoroughly gelatinized; if made in the morning just
before being served, they will not be digestible. In cases of
very weak stomachs, many articles of diet may be peptonized
with great benefit by using a small amount of a mixture of so-
dium carbonate and pancreatin, these being allowed to act for
a short time at a temperature of about 80° Fahr. Fairchild, of
New York, prepares powders containing these peptonized ma-
terials in convenient amount. Such peptonized foods are like the
old-fashioned preparations made with rennet and warm milk,
and will be well borne by delicate stomachs. An article that is
often wrongly prepared is barley. It may be softened and ex-
tracted with water, or it may be torrified so as to make a sort of
malt extract. In the latter form it is very suitable as a sub-
stitute for the distaste-like principle of the saliva in cases where
that secretion is deficient. It can easily be given mixed with
other food, as in puddings, for instance.

This summer we have been very successful in relieving the
irritability of the stomach and bowels of both children and
adults, due to temporary indigestion, by substituting first barley-
water alone, and after a time a wineglassful of barley-water,
with half a tumbler of milk, or its equivalent of condensed
milk.

Too little attention is given to the character of water. It is
sometimes very bad, containing either injurious mineral or vege-
table matter. The Boston water supply was much injured lately
by certain sponge forms.

Butter is an article of food which is often impure, and, be-
sides, objectionable substitutes for it are often sold. The mix-
tures of animal fats known under the names of oleomargarine
and butterine should not be used in the preparation of food.

Beef-tea contains often but little nourishment, and in debili-
tated conditions, such as most cases of typhoid fever, beef es-
trace made, not from the round of beef, but from the neck, in
which blood is found, will be much more nourishing. A val-
uable form of beef-juice can be prepared by cutting up in pieces
fresh beef, and placing it under a block of ice until, by the
pressure, all the blood has been extracted. With the addition of
a little salt, it has been found to be retained by the most deli-
cate stomach, and is very useful in cases of great exhaustion.

Dr. Albert H. Smith: The older we get the less disposed
we are to rely on medicine and the more on diet. The remarks
in the paper in reference to the importance of teaching physi-
cians the art of cooking are deserving of full indorsement.
On one point, however, I can not agree with the author of the
paper. He seemed to advocate the use of highly stimulating food
in acute diseases; in other words, the methods advocated by
Dr. Thomas King Chambers in his fascinating work—a work,
however, which has done great injury. Dr. Chambers's idea
was that all disease was due to depression, and therefore the
remedy was to stimulate the system. This is an attractive the-
ory, but is not true. In cases of disease attended with high
temperature, we only add fuel to the flame by the use of stimu-
lating food.

Nature has admirable powers of taking care of herself, even
under a starvation regimen. The use of a low form of diet,
with refrigerants and depressants, may often be of the greatest
benefit. I can look back on my early experience, and recall
cases in which, after operative measures, patients have been
treated on the theory that plenty of pabulum should be fur-
nished to the system, but such patients have perished. A strong
patient will in such cases do much better on a low diet. Adhe-
sive inflammation will be secured more satisfactorily on the low
diet system.

Dr. J. M. Barton: I had under my charge during three
years a patient who sustained life on about a pint of milk a day
—never more than a quart a day. He was a physician who had
his own views on questions of diet and therapeutics. Dr. A. H.
Smith is right in his position as to the importance of low diet
after operations, but in typhoid fever we have a very different indication. In the first case, i. e., after operations, food frequently acts as an irritant, but in the low fevers the patient is exhausted and needs support.

Dr. Forney: I am reminded of a compliment which I heard the younger Larrey pay to Ortila, the great French chemist. He said that he (Ortila) was the greatest cook that ever lived. He said Ortila understood the disintegrating power of hot water. The effect of thorough boiling is most important, and since the days of Washington it has been an article of war that beans should be boiled for six hours. In the Crimea marked difference was seen between the French and English troops on account of the superior attainments of the French officers and surgeons in reference to many of the details of a soldier’s life, and especially in cooking.

Dr. Selzer, in closing the discussion, said: I did not wish to include in the paper a discussion of the methods of preparing food, but merely to express the idea that it is important that doctors should know what to cook and how to cook. Many articles of food, that as ordinarily prepared are unfit for the sick, can be cooked so as to be palatable and digestible. Mrs. Rorer’s method of cooking liver is an instance of this. She exhausts it with water to remove blood, then places it on ice until required, when it is cut into thin slices and toasted; sweetbreads are somewhat similarly prepared.

As to the use of stimulating food, we must judge Dr. Chambers’s views by his own method. He draws the line between acute and chronic diseases, not making time the basis of the classification, but the tendency of the disease. Acute diseases tend to recovery, and these he leaves undisturbed; chronic diseases tend to fatal results, and in these he uses a highly nutritious diet, stimulating when a depressed state exists.

In reference to the suggestions made by different speakers as to the importance of systematic instruction of physicians in the art of cookery, I may say that such courses are now being organized. I do not think that such instruction can be advantageously given with pharmaceutical teaching. A woman’s taste and tact are essential to the art.

A Case of Amputation of the Breast, with Remarks.—Dr. Henry Leaman read the following paper:

Mrs. J. J. W., aged forty-eight, married twenty-nine years, is the mother of eight children still living, and has been the recipient of ten severe miscarriages. She presented herself at my office on the 1st of September, 1882, complaining of a tumor in her breast, which she had noticed for the first time three months previous. At that time a small pimple upon the surface of the skin served to call her attention to the swelling that lay beneath in the substance of her breast. Examination showed a tender enlargement, the size of an English walnut, situated deeply in the inner lower quarter of the left breast. She stated that during the past week she had experienced for the first time frequent, sharp, retracting pains shooting through the nipple. Menstruation had ceased with her six years previous, without giving rise to any trouble. She now had no cachexia, and was apparently in her usual health.

On the eighteenth of the same month she called again; the growth had not perceptibly increased, but she spoke of having pain in her breast bone. Amputation of the breast was recommended. The effect of this advice was to send her upon a blind pilgrimage through the desert of therapeutics. Now electricity, now pow-wowing, now homeopathy—each in its turn was tried with results equally gratifying to the patient.

The ignis fatuus which I had lighted brought her again to me on the 23d of April, 1883. The tumor then was of an oval shape, and about four inches in length. From its inner anterior surface were extending two cornua, slightly ulcerated, about three fourths of an inch in length. The skin over the tumor was deeply congested, red, and inflamed, as was also the skin for several inches around. The tumor in front rested upon the cartilages of the rib, but was movable. The glands in the axilla were slightly involved. With the assistance of Drs. Hatfield, Brubaker, Welch, and R. Leaman, the breast was removed under the spray, on April 26, 1883, and Lister’s dressing applied.

One nodule of hardness was removed from the axilla. At the external and the cut surfaces could not be approximated within two inches, owing to the necessary ablation of tissue.

April 27th.—Patient doing well. Temperature 99° F., pulse 112 at 10 a.m.

April 28th.—Temperature 99° F., pulse 104 at 10 a.m. The breast was dressed under the spray at 10 p.m. Temperature 99°, pulse 104.

April 29th.—Temperature 98° F., pulse 96 at 10 a.m. April 30th.—Temperature 99° F., pulse 96 at 10 a.m.

May 1st.—Temperature 98° F., pulse 92.

May 2d.—Temperature 97° F., pulse 84; dressed the wound the second time under the spray; the drainage-tube was removed, as were also some of the sutures.

May 3d.—Temperature 97° F., pulse 80 at 4 p.m.

May 4th.—Temperature 97° F., pulse 100. Dressed again under spray.

May 6th.—Dressed under spray; removed the sutures and two ligatures. Temperature 98° F., pulse 104.

May 7th.—Temperature 98° F., pulse 104. Patient sitting up.

May 8th.—The posterior three fourths of the incision entirely healed and healthy. The anterior one fourth was perfectly healthy and granulating rapidly. All sutures and the remaining ligatures were removed.

On and after May 10th the wound was dressed with iodiform, cosmolene, and salicylated cotton, under which treatment the wound rapidly healed. Dr. Brubaker made a histological study of the growth, and pronounced it carcinoma.

As soon as the cicatrix was complete, neuralgic pains began to be felt in the left arm, right leg, and body. At first the cicatrix remained perfectly healthy in appearance. Subsequently, however, a nodule appeared in the lower part of the neck, behind the left sterno-clavicular articulation. Next, the left axilla, the posterior and healthy part of the cicatrix, both began to show hardening. At present there is a chain of nodules along the whole cicatrix—one, large and painful, is felt over the cartilage of the third rib on the left side. The left axilla is but one hard pyramid. The left hand and arm are swollen. A pain of a lancinating, burning character is referred to the left scapula, arm, and axilla, occasionally shooting in the course of the incision.

The apparent freedom from involvement of the axillary glands at the time of the operation, and the rapid development of the disease after the healing of the cicatrix, would seem to point to the idea that the original tumor was but a local nodule for a constitutional trouble, and that, this having been destroyed, a general efflorescence of the disease ensued. A kindred idea is found in the popular belief, that a manifestation of phthisis may follow the operation for the cure of anal fistula. The observations on the change of life in women would seem also to bear upon the same point.

Dr. Brubaker’s Analysis of the Tumor.—“Upon section, the tumor is firm and hard, and presents a white, glistening surface, from which can be scraped a small quantity of fluid matter. Under the microscope the connective tissue stroma is seen to be abundantly developed; in its meshes are developed epithelial cells, some of which have undergone degeneration. In some situations the cells are arranged in a linear manner, while in others they form groups or nests.”
Dr. Baldwin: I remember that the late Dr. Atee spoke of the effects of arsenic in carcinomata, and gave a number of cases in which he used it with the apparent effect of preventing the return of the tumor. I employed it in a case on which operation was performed in 1875, the patient being put on the use of Fowler's solution, continued until 1876, when the growth redeveloped, and a second operation was done in 1878; no return has occurred to this time. The use of arsenic was discontinued after the second operation. During the formation of the second growth some trouble occurred in the lung, and cancer of that organ was feared, but it disappeared after operation.

Dr. Forrester: Dr. Leaman speaks of a period of efflorescence after operation, by which I understand a general development in different organs; this, as he remarks, does not always occur after the first operation. In 1864 I removed a cancer from the breast of a lady. In 1867 a hardened growth appeared in the cicatrix. It was not removed at once, as it was then giving no pain. In a short time, pain having developed, it was removed. It returned a number of times, and was each time removed until it developed in attachment to the interscapular cartilage and the muscles, and then I declined to remove it, although the patient very much urged me to do so. It continued to increase, and in eighteen months it involved the integument on the clavicle and sternum. Its condition was much aggravated by various caustic applications. Finally some irregular porties attempted to remove parts of the diseased mass, and this was followed by an efflorescence, and a number of organs in the thorax and abdomen became involved. The patient died eighteen months after the last attempted operation.

I have heard Dr. George W. Norris speak of this condition of efflorescence and its likelihood to occur in patients upon whom the cautering and escharotic treatment had been practiced. After such treatment he advised non-interference with the knife.

Dr. J. M. Barton: I have been interested in examining the advertisements and circulars of the empires who claim to cure cancer without operating, and I find them reporting cures of cases of over forty years' duration. Now, as cirrhosis, if left untreated, does not last usually more than four years, it must be that these long cases are benign tumors.

Even when the knife does not cure, it may prolong life—make it more tolerable. Operation offers us ten per cent. of recoveries. Dr. Leaman's case may be regarded as typical. The almost immediate return in the axilla is suggestive of the possibility that some affected gland had escaped removal. The removal of the entire breast in the earlier stages gives chance of total recovery, and in the later stages, with ulceration, operation is also useful; but in the intermediate periods, when the tumor is extensive and adherent to the adjacent structures, non-interference is best.

Dr. Albert H. Smith: I am glad to hear Dr. Barton advocate the repeated use of the knife; I believe in attacking the tumor every time it appears, for, at the least, life may be prolonged and made comfortable, and the patient may be spared the suffering and loathsome discharges of the advanced stages of the disease, conditions which make her a source of misery to herself and to those around her. Cancer is doubtless a local disease, although a constitutional taint or tendency is probably inherited. Yet, if the tumor be removed early, a cure can be obtained. Dr. Leaman's patient did not do well, because she did not follow the advice he gave at first. Removal of the breast should be complete; every reappearance should be met by operation. I recall the case of a patient from whom, at the first operation, no axillary glands were removed, but at the second twelve were taken out. Two more operations were subsequently performed; at the last one a very large amount of tissue was removed, but perfect union was obtained. Operation should cease when the condition is such that union by first intention can not be obtained. In this particular I can not agree with Dr. Gross, who pays no attention to the size of the cicatrix, or the question of union by first intention. The patient just referred to has been well during this summer, but is now beginning to manifest infiltration, and the condition is such that primary union can not be obtained, and I do not consider operation permissible. Under the modern advances in antisepsis surgery, operative interference in cases of cancer becomes simple and entails little suffering, and the after-treatment is not difficult.

Dr. Barton: The important point in operation is to make a complete cleaning out of the affected glands, and the obtaining of this must not be interfered with by consideration of the amount of tissue to be removed, or by the desire for primary union. Where much tissue is removed, the after-treatment is more simple than where flaps are made; no counter-openings are needed; no drainage-tubes; no pockets of pus are formed; but little, if any, fever occurs; the wound usually goes on uninterrupted to full cicatrization. In hospital practice I rarely have to see a case after operation from which the breast has been thus removed. I can not recall a case in which the disease returned in the cicatrix so formed, though it often returns in the axilla. I remember a case in which three operations were performed upon secondary axillary growths in a period of four years—the last operation being amputation of the arm, ligation of the axillary artery, and removal of the growth—yet the resulting cicatrix from the first thorough operation remained perfectly soft and healthy.

Dr. Leaman: The case I have reported is an ordinary one, and the operation was certainly performed with ordinary care. The axilla was opened, and all present agreed that no glands were affected except the one removed. The first symptoms of return were shooting pains in the fingers, referable to a nodule near the insertion of the sterno-clido-mastoide muscle, behind the left sterno-clavicular articulation. Subsequently the axillary glands were involved. A few small nodules have since appeared over the seat of the first tumor. I think it important to remember that surgeons may make mistakes; that some of the cases diagnosed as cancer, and apparently cured by operation, may be benign tumors. In my experience, arsenic has not been of use in carcinomata.

Remarks on the Chicago Beef Wire Skewer.—Dr. W. R. D. Blackwood read the following: The supply of good, wholesome meat to a large city is a problem involving many points of great importance. Many cattle are slaughtered within a few hours after reaching the abattoirs, before the feverishness and excitement resulting from a long railroad journey have abated, and the meat under the circumstances is not nearly so good or suitable for food as it would be, even in healthy and prime animals, were it killed after a due time of rest. For a short time past, beef slaughtered in Chicago and brought here in refrigerating cars has attracted the attention of those able to judge the article according to its merits, and for quality it is pronounced fully equal to any heretofore put on the market, and far ahead of the great bulk previously sold in the city, so far as a wholesome, sound, and moderate-priced beef is concerned. The animals are selected from approved droves, and well fed, watered, and housed for a definite and proper time before killing, and the product, therefore, is not only in its appearance perfect, but, in the vital point of fitness for wholesome, nutritious, and palatable food, it is unrivaled.

Some weeks ago a sensational attack was made on this variety of beef, in the interest of a clique of butchers in this city, who, knowing the value of the Chicago article, were afraid of the effect on their business when it became better known to
The public, and the silliest pretext, among others, advanced, was a supposed danger to consumers from the novel skewers employed to fasten the labels on the hind- and fore-quarters, these being of barbed wire, such as I exhibit to you to-night. It was predicted that an epidemic of harpooned tongues, tonsils, and pharynges would ensue from swallowing unawares by consumers the numerous wire skewers concealed in the meat, and I am informed that for a time a serious falling off in the sales actually resulted from fear on this point. You will readily see that any one who should try to gulp down a morsel of meat large enough to hide this fastener must at the same time be in a famishing condition, have the appetite of a tiger, and need lessons in table etiquette, to put it mildly.

The labels which are attached—one to each quarter only—are removed by the butcher before cutting up the meat, and could not, even if allowed to remain, fail to attract the attention of both cook and eater. Mr. Bradley, of the Great Western Market, is the largest dealer in this excellent beef in this city, and he has kindly supplied me with samples of the bars. The claims which he makes for the particular beef under consideration are worthy of notice, as his experience in business for some years past is unequaled in this city, and the enormous quantity which he distributes to a large section of surrounding country fully justifies the high value he places upon it. I am glad to confirm what he says, from personal experience in my family. The meat is simply delicious, and excels anything we have previously had from the best butchers of the city.

A New Use for an Old Instrument.—Dr. Leaman called attention to the fact that he had found the hooked end of Dr. Gross's ear and nose instrument the best and safest means of rupturing the membranes in labor.

Meeting of September 19, 1883.

Aneurysm of the Ascending Posterior Part of the Aorta.—Dr. Charles M. Seltzer said: I am indebted to Dr. W. Duffield Robinson, Resident Physician of the Eastern State Penitentiary, for the pleasure of being allowed to exhibit this specimen. It is of especial interest to me because I saw the case several times during life.

L., aged thirty-five years, height five feet seven inches, usual weight one hundred and forty-two pounds, was admitted to the Eastern State Penitentiary, under a two years' sentence for larceny, in September, 1882, previous to which time he had been four months in a county jail. Sixteen years of his life were spent in various prisons under different sentences. No family history could be obtained.

His medical history dates back sixteen months ago, when he complained of pain between the shoulders, but he continued in comparatively good health until six months ago, when he began to complain of diffuse intercostal pains in both sides and pain in the epigastrium; also poor appetite, nausea, and indigestion; anemia, and general debility. Upon careful examination, no organic disease was discovered. The heart was rather weak, but otherwise normal. Thoracic percussion was normal, except slight increased dullness under upper part of the sternum. Pulse feeble, but otherwise normal. There was no syphilitic history, no anemia, no palpitation of the heart or precordial pain, and no intercostal pain during the past year. No bulging of the chest-walls, either anteriorly or posteriorly. No discoverable aneurysmal bruit. In fact, there was nothing to indicate any organic disease. The case was examined by six reputable physicians, and all of them arrived at the same negative conclusion. The patient's physical condition steadily grew worse, and he was given the liberty of a large yard, excuse from work, and allowed a plentiful nutritious diet, general tonics, and anodynes for the neuralgias. Under this treatment he seemed to improve, but the neuralgias and insomnia continued.

Three weeks ago (August 28, 1883), while sitting in the yard, he suddenly grew very pale, complained of faintness, and was caught while in the act of falling to the ground. He was carried to the hospital department and given stimulants. The physician arrived in a few minutes and found him dying.

A post-mortem examination was made a few hours later by Dr. Robinson, assisted by Drs. Rudderow, Taylor, Weideman, and Seltzer. A large tumor, found just above the heart, proved to be an aneurysm of the posterior ascending portion of the aorta. The sac contained one and a half pints of freshly clotted blood, unorganized, and its posterior wall was formed from three dorsal vertebrae, the bodies of which were very much eroded. There was also some erosion of the corresponding ribs, and a slight bulging of the sac between them. The heart was very small, but free from disease. No other organic trouble observed.

A careful review of the case suggests the following thoughts to me: 1. That the disease was one of long standing, and that, on account of the enforced quiet life of the subject, no inconvenience was experienced until erosion of the vertebrae was so extensive as to cause neuralgias of the adjacent nerves, and slight intercostal pain of short duration. 2. That the case was rendered still more obscure by the facts that the opening into the sac was large, and that considerable portion of the sac-wall was made up of bone—both of which tend to destroy the possibility of there being a diagnostic aneurysmal bruit. 3. That if there had been much intercostal pain, due to the erosion of the vertebrae, and it had been treated by introducing a septon or issue in its vicinity, as has been lately recommended by standard authority (Thomas Hayden, Quain's "Med. Dict."); there would have been considerable danger of puncturing that portion of the sac protruding between the ribs. 4. That there can be a very large thoracic aortic aneurysm without any bulging of the chest-walls, and that it may erode much of the bodies of the vertebrae without causing spinal curvature. 5. That, as there was no hemorrhage into the thoracic cavity or canal of the spinal cord, death must have been due to pressure on some of the cardiac nerves or ganglia, and consequently collapse from heart-failure.

Femoral Hernia in an Aged Patient; Strangulation; Operation with Cure.—Dr. W. R. D. Blackwood read the following history:

Mr. B., aged seventy-three, tall, thin, but bearing his years well, and with a previous history of good health, was taken ill with supposed cholera morbus on Saturday, August 11, 1883, but, from the suppression of alvine dejections shortly after the seizure, and the rapid change of the vomited matter to a manifest stercoraceous fluid by the time his physician—Dr. John Irison—saw him, the diagnosis of the family was set aside for one of more grave nature. The gastric distress was very great, the desire to vomit urgent, and the act occurred at short intervals. Previously to his illness the gentleman had been extremely constipated, and the amount of liquid and semi-solid fecal matter rejected per oram was simply inconceivable except to those who saw it. At each instance of vomiting a fair-sized wash-basin was half filled, and the total quantity thrown up before relief ensued was, to speak within bounds, fully three gallons, showing the enormous distension of the intestine which may occur in chronic constipation.

The case was believed to be one of obstruction, with possible invagination of the bowel, and efforts were made toward overcoming the difficulty and obtaining an operation in a normal direction, but without success. The question of strangulation by hernia was not at first accepted, because, although there existed an evident swelling at Pouchard's ligament, the size of it was so small as to be taken for an enlarged gland, the patient having had glundular enlargement previously. There was no local pain, no tenderness, no tension, no dragging sensation at the site of the swelling, no tympanities—in short, the usual local signs of strangulated hernia were absent. The little tumor also was movable to such an extent as to easily deceive one, even when closely examined. The doctor having asked my opinion as to the condition of the patient, we saw him together, and I coincided with him as to the difficulty in stating positively to the family the evidence of hernial strangulation, but, as the patient was rapidly sinking from exhaustion, we decided to
make an exploratory incision and determine the nature of the enlarge-
ment, the justice of this being explained.

The patient was chlorized, and, after cutting down to the sac, the
mass was found to be an enterico-epiploic. The sac contained very
little serum, and, considering the fact that strangulation had doubtless
existed for at least thirty-six hours, the bowel, though highly congested,
was in good condition. The gut was tightly nipped at the crural ring
and was nearly empty, which accounted for the small size of the tumor.
The hernia was internal to the femoral vessels, but closely adherent to
them. It was reduced with some difficulty and pushed far up to clear
the deep thrust of the needle in closing the wound. The stitches, four
in number, were deeply taken, and the ligature obliterated as nearly as
possible. A compress of lint, wet with a mixture of Canada turpen-
tine, oil of sweet almonds, carbolic acid, and glycerin (an excellent
dressing), was applied under a splice bandage of the groin, and the pa-

tient made comfortable in bed. He reacted well from the operation,
vented freely once thereafter, and in an hour and a half passed an
alvine dejection without pain or difficulty. The appetite returned
moderately at once, food was well retained, and his strength returned
nicely. For forty-eight hours the wound did well, healing for one half
its length by first intention, but then inflammatory action set in and
free suppuration ensued. In a week, however, the wound had closed,
and the old gentleman was able to walk his room with comfort.

The diagnosis of femoral hernia is, at times, not easy, being,
as here, liable to be confounded with enlarged glands, or local-
ized varix of the saphena. There was no impulse on coughing, no effort
at reduction affected it, and, excepting only the very small tumor, all the
local signs of strangulated gut were absent. The advanced age of the patient was against him, and his
depressed vital power was a bad factor. The result shows the
value of exploratory operation under the circumstances, and I
believe that the attendant is unfaithful to his patient if he does
not insist upon it in every suspicious case. The wound is of
little account; it does not enhance the danger which is already
imminent, and it may, as here, save a valuable life.

SCHIRBUS OF THE MAMMARY GLAND.—Dr. W. R. D. Black-
wood also read the following: The tumor which I exhibit to
you this evening was removed from a lady this morning. The
growth has only been noticed by herself for about seven months,
but it has undoubtedly existed for a longer period. It is an
atrophying schirbus of the right mammary gland, is densely
hard, and was all that remained of the breast, which was thor-
oughly extirpated, together with the underlying fascia, all
coverable lymphatics, and a portion of the pectoralis major
muscle. The character of the growth renders her chances for
complete recovery doubtful, as such varieties of cancer are re-
current in a high degree.

She reacted well from the operation, but had a moderate
secondary hemorrhage four hours after I left her, which was
controlled by pressure. I learned this evening that she had a
decidedly hemorrhagic diathesis, which renders my peace of
mind unpleasant just now, for as it never rains but it pours, I
am worried by two cases three miles apart, which tend to keep
me in hot water, which, though efficient as a haemostatic, is
undesirable as a factor in personal comfort.

VERIFORM MUCOUS DISCHARGE FROM THE RECTUM.—Dr.
Benjamin Lee spoke as follows:

The interest of this specimen lies in the close resemblance
it bears to a tape-worm. This is by no means so striking as it
was when I received it a week ago. It was sent to me, in fact,
by the mother of the patient, a young lady residing in a neigh-
boring city, under the impression that it was a portion of a tape-
worm, partly dissolved by medicine. The history is briefly this:
The patient had been under my care, some years since, for a
uterine displacement with hemmorhoids. The latter had pretty
much disappeared, but had been succeeded by hemmorhages from
the bowels—not large in quantity or very frequent. About
four weeks since, she noticed that she was passing segments of
a tape-worm. Another member of the family having been re-
cently infested in the same way, and having been successfully
injected with the use of pumpkin-seed in milk, according to an old
formula of Paul Beck Goddard's, which was among the family
treasures, she determined to treat herself on the same plan.
Accordingly, after a fast of thirty-six hours, she took half a
tumblerful of pounded kernels of pumpkin-seed, stirred into the
same quantity of milk; and, two hours after, three tablespoon-
spoons of castor-oil. This brought away only segments of the in-
truder, alive and active. After an interval of thirty-six hours
during which she took but one meal, she repeated the two doses,
with the same effect, except that toward the end of the purga-
tion the segments appeared dead. The purgation, however, was
soon followed by profuse and protracted hemorrhage from the
bowels, which, in addition to the action of the medicine and the
long abstinence from food, left her very much exhausted. The
following week she visited me at my office. Examination with
the finger showed retroversion and partial prolapse of the uterus.
The hirsute remains of external piles, no internal piles or
or tumors of any kind, a thickening of the posterior wall of the
rectum, and a velvety or fibrillos feel to the mucous membrane
overlying this thickened portion. As frequent hemorrhages
had occurred since that which followed the use of the tincture,
I strongly advised against any further immediate attempt on the
parasite. I instructed her to take an injection of ten grains of
sulphate of zinc in an ounce of flavessed-tea at bedtime every
night, to be retained, and an injection of a pint of flavessed-tea
the following morning to produce an easy evacuation.

A week later she sent me down this specimen, saying that
she had passed several more like it, and wishing to know if it
was not the worm partially dissolved. She again visited my
office on the fifteenth of this month. There had then been no
hemorrhage for five days, and whereas at first it was with the
greatest difficulty she could retain the injections for an hour,
she was now able to retain them all night with comparative
comfort. The discharges of mucus, on one day amounting to
five or six, did not now occur as often as daily. They are pre-
ceded by a sense of weight and tenesmus, much as the hemor-
hages were, which is relieved after they have taken place. I
ought to say that I had also prescribed fifteen drops of fluid
extract of ergot four times daily, I now order the dis-

cance of the injections, and a diminution of the ergot to ten
drops. Upon examination, the rectal mucous membrane felt
decidedly more natural. I yesterday received a note from her
saying that she had passed fifteen inches of the worm very close
to the head, but could not make sure that the latter had come
away. Should this prove not to be the case, I shall, when the
mucous membrane of the rectum has become sufficiently re-
paired, administer pelletierine, having used it successfully quite
recently. The patient, a gentleman living also out of town,
writes me that the most notable effect of the medicine, apart
from its dislodgment of the intruder, was "extreme dizziness,
and a feeling of the eyes as if starting from the sockets, accom-
panied by uncertainty of vision." "The feeling of nausea," he
adds, "was, however, by no means the distressing nature
that I told you accompanied a previous attempt upon the worm."
The attempt he refers to was made, I think, in Germany, and
the remedy used was the pomegranate; and so intense was his
suffering from deadly nausea that he has been content to play
host to his not very troublesome guest now for some years,
rather than undergo a similar experience of wretchedness, be-
ing only driven to it finally by his approaching nuptials.
**Miscellany.**

**Therapeutic Notes.** _Rhus Toxicodendron_ as a Remedy for Rheumatic Inflammation of the Sheaths of Nerves and Tendons.—Thomas Gifford, M. D., of Laurel, Indiana ("Cincinnati Lancet and Clinic," August 25, 1883), recommends _Rhus toxicodendron_ as a curative agent of the "green fever" rheumatism in some forms of chronic rheumatic affections of fibrous tissues. For instance, what is commonly termed "sciatia" may be a pure neuralgia of the sciatic nerve, or it may be a rheumatic inflammation of the sheath of that nerve." In the neuralgic form, _rhus toxicodendron_ is not the remedy; but in the rheumatic form it is of marked efficacy, if used according to certain directions. The powdered leaves, the infusion, and the extract are nearly inert, and therefore the drug has fallen into disrepute. Dr. Gifford pursues the following plan: During the last week of May or the first week of June he gathers the leaves of the _Rhus toxicodendron_ (the _Rhus radicans_ will not answer). If practicable, leaves grown in a shady place are selected, and they are gathered after sunset on a damp, sultry day. They are cut fine and macerated two weeks, in a colored bottle, with deodorized alcohol, per cent., in the proportion of one part of the leaves to two parts of the alcohol. The filtered liquid, which should be kept in well-corked colored-glass bottles, contains concentrated _toxicodendric_ acid, in which the medical properties of the plant reside. This is to be diluted with pure deodorized alcohol on the decimal scale. Two drops of the third dilution, taken night and morning, will act benefically within forty-eight hours on the rheumatic form of the disease. When the pains have abated somewhat, one dose at evening is to be taken until the cure is complete. "This may look like small dosing," he says, "but I have found one case in which it was too large, and none where it was too small." In the case referred to, marked rhus poisoning occurred on the third day. After more than twenty years' experience with _Rhus toxicodendron_, Dr. Gifford has come to the conclusion that it exerts a decidedly curative action on diseases of the fascial sheaths of nerves and tendons. Rhus poisoning may be promptly and certainly controlled by freely applying _Lobelia inflata_ externally (two parts of the fluid extract to one of pure glycerin), and by small doses of aconite and belladonna, internally, given alternately every two hours until the itching and burning abate.

**The Sanitary Condition of the Mississippi Valley.**—Dr. John H. Rauch, as executive officer of the Sanitary Council of the Mississippi Valley, in a recent monthly report, says that during the month of August the supervision of the river and rail inspection service, by the executive committee of the sanitary council, was confined to New Orleans, Vicksburg (at Fort Adams), and Memphis (at President's Island). At New Orleans sixty-five steamboats and other river craft, with an aggregate capacity of 71,517 tons, and carrying 2,681 officers, crew, and passengers, were inspected and duly provided with the certificates of the sanitary council. On the Illinois Central and Louisville & Nashville railroads, at the same point, there were inspected 139 freight trains, comprising 1,911 loaded, 1,523 empty cars, together with their crews of 534 persons. At the inspection stations at Fort Adams, below Vicksburg, and on President's Island, below Memphis, an aggregate of 228 river craft, with a capacity of 224,440 tons, and carrying 18,025 persons, were inspected. These boats were found in good sanitary condition, and no suspicious illness appeared among those on board, although there were a number of cases of the malarial fever of different forms, mainly intermittent. An aggregate of 770 ocean vessels, river craft, and freight trains, with a capacity of 893,231 tons, and carrying 27,888 officers, crews, and passengers, have been inspected under the supervision of the council since July 1, 1883.

With the exception of one suspicious case in the early part of the month in Jackson County, Miss., on Fort Bayou, near the coast, there has been a very unusual absence of anything like yellow fever in the area in which the inspection service is maintained. In the case alluded to, the Mississippi State Board of Health acted upon the hypothesis that the disease was yellow fever, although the diagnosis was doubted and the weight of opinion against that conclusion. An inspector was at once put on duty in the district, and the locality was placed under a quarantine of isolation for fifteen days; disinfection was resorted to, and nothing further of a suspicious nature has since developed.

Dr. Rauch adds that New Orleans has not been so free from alarm, or cause for alarm, during the corresponding months of many years as during the sixty days referred to.

**The University of Nebraska.**—We learn from the eleventh annual catalogue that the faculty of the College of Medicine consists of the following professors: A. R. Mitchell, M. D. (Dean), anatomy; Paul Grossmann, M. D., surgery; L. A. Merriam, M. D., practice of medicine; H. B. Lowry, M. D., physiology, materia medica, and therapeutics; W. M. Knapp, M. D., obstetrics and diseases of women and children; H. H. Nicholson, chemistry; L. B. Grady, M. D., diseases of the eye and ear; the Hon. O. P. Mason, medical jurisprudence; and N. J. Beachley, M. D., demonstrator of anatomy. The university being endowed, all persons, whether men or women, who are found qualified to pursue the study of medicine are admitted without charge, except a matriculation fee of $5. The course embraces three years of six months each. The study of practical anatomy and practical chemistry is among the requirements for graduation. In lieu of a thesis, a clinical report is required.

**The Theory of Filth as a Cause of Disease.**—Dr. Edward Ballard, a medical inspector under the English Local Government Board, made use of the following language in his remarks at the recent meeting of the British Medical Association ("British Medical Journal," Aug. 28, 1883): "Another common theory is that diarrhoea is due to filth, and especially excremental filth. I do not say that excremental filth has nothing to do with it; but in the town of Nottingham there is less excremental filth-nuisance than perhaps in any town in England; there is the most careful removal, twice a week, of excrement, which is received into pails and covered over with ashes. I have been all over Nottingham, and have never smelt anything like an excremental odor in the town; yet Nottingham is one of the towns with a high death-rate from diarrhoea. I have a difficulty in accepting this kind of filth as a leading cause; and I may say the same of surmise. I suppose there is a town in England, which is less free from a nuisance, which is as close as Nottingham, in which there is less care taken about pollution of surface than in a certain town in Cornwall—Helston. I do not know any town more filthy in regard to surface at the rear of dwellings; and yet in Helston summer diarrhoea is not prevalent, and there are very few fatal cases. If filth would do it, one ought to have it excessively in certain parts of Plymouth; yet certainly it does not occur there in the same degree as in other towns. I may mention other things as not being the leading cause of summer diarrhoea. That they may have more or less to do with it, or with its fatalities, I do not deny; but there is something underlying the whole of these, and what that something is it is my business to find out."

**Vaccination and Insanity.**—In an interesting and suggestive article on Variola and Insanity, by Dr. James G. Kierman, of Chicago ("American Journal of Neurology and Psychiatry," August, 1883), he relates certain experiments undertaken by himself and Dr. M. J. Madi- gun to ascertain the effects of vaccination on the insane. The experimenters were not aware at the time of Calastri's suggestion of such an inquiry to elucidate the reciprocal action of small-pox and insanity. Dr. Kierman says:

"Progressive parotids, atomic, simple, and agitated lymphaneis, primary mononanias with depressing delusions, terminal dements, and hebephrenias were vaccinated. The phenomena therefrom resulting might be divided into four great classes: First, those in which the vaccinia exerted a beneficial effect upon the pre-existing insanity; second, those in which it unfavorably influenced this; third, those in which dangerous complications resulted; and, finally, those exceptional cases in which dermal phenomena were present. The psychoses on which vaccination exerted the most marked favorable influence were lymphaatia atomia and agitata, progressive parotids, rarely in acute lymphaatia, primary mononanias, and chronic confusional insanity. In all cases wherein such influence was exerted, the vaccination was followed by a high fever and marked general constitutional disturbance. Diniusions of infection with syphilis, of loss of Identity, of paranoia, of poisoning, and in several cases of infection with small-pox, were frequently
found after the vaccination. One case of a new delusion has already been mentioned. In progressive paraectes certain trophic changes made their appearance. The toe-nails in four cases dropped off. In one case ophthalmia made its appearance during the vaccinal fever. In a syphilitic progressive paraetic the lactic affection seemed to take on a malignant type. Three atomic lymphanias who had markedly deficient capillary circulation suffered from gangrene of the toes and fingers in consequence of vaccination. There were formed on a few progressive paraectes large bullae, which subsequently gave way to ulcers of a very indolent type. In two progressive paraectes apoplecticiform attacks came on during the vaccinal fever. In ten progressive paraectes large abscesses of the secondary secernences after the vaccinal fever had already subsided on the seat of the pre-existing vaccinal eruption. The hair of one progressive paraetic became gray on one side of the head, while the eruption from vaccinia remained confined to the opposite side of the body. Two atomic lymphanias who were suffering from phthisis seemed to be disastrously influenced as regards the pulmonary affection which had been previously running its course without marked febrile disturbance, but thereafter had marked rises in temperature. One lymphania became temporarily glycosic. There was a pretty general eruption resembling varioila. On the fever subsiding (in at least ten cases it reached 102° F.), the patient, if a lymphania, was found to be much more cheerful, and occasionally delusions of persecution seemed to be temporally in abeyance. One patient permanently recovered, and, as he had exhibited no change previous to the vaccination, it is probable that this exerted a marked influence. The progressive paraectes were attacked by boils soon after recovering from the vaccination, and were for a short time rational, but the physical symptoms of the disease remained unchanged. The agitated lymphanias were quiet and cheerful during the constitutional disturbance from the vaccination, but, after it had passed away, all but two returned to their usual condition. These improved from that time, and finally recovered. Three primary monomanias were markedly quiet and relatively rational during the vaccinal fever. Four cases [sic] of chronic confusional insanity talked coherently and relevantly during the vaccinal fever, but resumed their usual condition on recovery.

DELPHI FROM AN ATTEMPT TO REDUCE AN OLD DISLOCATION OF THE SHOULDER.—The "New Zealand Herald" reports the occurrence of an accident in Castlemaine, Victoria, on March 12th last, to a Mr. Taylor, who fractured his arm and at the same time sustained a dislocation of the shoulder on the same side. The fracture was treated by splints, and the injury was so far recovered from that the patient was able to attend to his business, and complained only of stiffness at the shoulder. On May 13th an attempt at reduction of the dislocation by pulley extension at the wrist and counter-extension in the axilla was made, the patient being under the influence of chloroform. After extension had been made for some time the tissues in the axilla gave way; the wound thus made was sewed up; hemorrhage then occurred, which was controlled by pressure, but next day the finch was found to be gangrenous and was amputated; death occurred within twenty-four hours. A coroner's inquest was held on the case, and a verdict of "death from misadventure, no blame being attached to the doctors," was returned. The account from which we have quoted does not give us full information about the case, and without further facts it would be impossible to express any opinion as to the line of practice here adopted. As a rule, in cases of fracture complicated with dislocation, it is best to set the fracture very firmly in splints, and then at once attempt reduction of the dislocation under chloroform. In attempting to reduce old dislocations it is important to remember that the chief reliance must never be placed upon extension. The first obstacle to be overcome in such cases is the adhesions which the displaced bone has formed to neighboring structures; and these adhesions can only be safely, and also most easily, broken down by rotation and similar manipulations. When this difficulty has been got over, that of the locking of the bones is met with; and, while extension may overcome this, manipulation is usually easier, and it is always safer. The aim of extension is to overcome muscular spasm; and now that we can accomplish this by means of anæsthesia, and in some cases by well-conducted manipulation, its role in this department of surgery is very small. The case referred to above illustrates one of the dangers attending the operation of reducing old dislocations, and shows the necessity not only of always keeping these perils in view, but also of informing the patient and his friends with the fact that the operation is one of some gravity, attended with risk of serious complications.—Lemot.

LEAD POISONING.—Sugar of lead is sometimes used in preparing silk thread which is sold by weight and not by length. A means of detection is sometimes the sweet taste which sugar of lead silks possess. A case of lead poisoning of a sewing woman, who held the silks in her mouth, is recently reported.—Sanitary News.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from September 22, 1883, to September 29, 1883.—De Loffres, A. A., Captain and Assistant Surgeon. Assigned to duty at Fort Niagara, N.Y. Par. 5, S. O. 182, Department of the East, September 27, 1883. —Havert, W. S., Captain and Assistant Surgeon. Assigned to temporary duty at post of San Antonio, Texas. Par. 10, S. O. 120, Department of Texas, September 21, 1883. —Reed, Walter, Captain and Assistant Surgeon. Referred from duty at Fort Omaha, Neb., and assigned to duty as post surgeon, Fort Sidney, Neb. Par. 5, S. O. 182, Department of the East, September 22, 1883. —Shannon, W. C. C., Captain and Assistant Surgeon. Assigned to duty at Fort Bridger, Wyoming. Par. 8, S. O. 102, Department of the Platte, September 19, 1883. —Appel, A. H., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort Warren, Mass. Par. 8, S. O. 181, Department of the East, September 23, 1883. —Carter, W. F., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Washington Barracks, D. C. Par. 8, S. O. 182, Department of the East, September 27, 1883. —Richard, Charles, First Lieutenant and Assistant Surgeon. Referred from further duty at Creedmoor, New York, to return to his proper station, Fort Adams, R. I. Par. 1, S. O. 180, Department of the East, September 24, 1883. —Richard, Charles, First Lieutenant and Assistant Surgeon. Granted leave of absence for two months, with permission to apply for extension of two months. Par. 1, S. O. 49, Military Division of the Atlantic, September 25, 1883. —Wakeman, William J., First Lieutenant and Assistant Surgeon. Referred from temporary duty at Fort Sidney, Neb., to rejoined his proper station at Fort D. A. Russell, Wyoming. Par. 5, S. O. 103, Department of the Platte, September 22, 1883.

NAVAL INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending September 29, 1883.—Surgeon G. B. Beardsley granted leave of absence for six months, with permission to leave the United States. —Passed Assistant Surgeon A. A. Austin, orders to Naval Hospital, New York, revoked, and placed on waiting orders. —Passed Assistant Surgeon George C. Lippincott ordered to the Naval Hospital, New York. —Medical Director George Peck detached from the Naval Hospital, Mare Island, Cal., and placed on waiting orders. —Surgeon D. McMurtrie and Passed Assistant Surgeon M. H. Crawford ordered to report at Washington, D. C., October 3d, for Medical Survey.

SOCIETY MEETINGS FOR THE COMING WEEK.—Monday, October 7th: New York Ophthalmological Society (private); New York Medical-Historical Society, Tuesday, October 8th: American Academy of Medicine (New York—first day); New York Surgical Society; East River Medical Association (private); Jersey City Pathological Society; New York Medical Association; Trenton Medical Association (private); Medical Societies of the Counties of Essex, Green, oneida, Ontario, Rensselaer, Tioga, Ulster, and Wayne, N. Y., Bergen and Cumberland, N. J., and Litchfield, Conn., Wednesday, October 10th: American Academy of Medicine (second day); Tri-State Medical Association (Fort Jervis, N. Y.); New York Pathological Society; Medical Society of the County of Cayuga, N. Y. Thursday, October 11th: New York Laryngological Society (private); New York Society of Medical Jurisprudence and State Medicine; Public Health Association of New York; Brooklyn Pathological Society, Friday, October 12th: Yorkville Medical Association (private); Medical Society of the Town of Saugerties, N. Y. (annual). Saturday, October 13th: New York Medical and Surgical Society (private).
HYDATIDIFORM DEGENERATION OF THE PLACENTA.

By HENRY O. MARCY, M.D.

When we remember the diversity of opinion yet held upon the development of the placenta, its histology, and even in relation to its important fundamental physiological functions, we can not consider it remarkable that there should exist the greatest of uncertainty and confusion of opinion relative to the morbid changes to which this organ is subject. Errors are perpetuated with wonderful pertinacity. Writers of text-books are seldom original investigators, and certainly could not be expected to have personally surveyed the entire field which they must go over in a systematic treatise. Thus one writer quotes from another, and often is it only after long research that the error is traced to its source.

When misconceptions of the anatomy and function of an organ prevail, and thereupon has been reared an erroneous standard of normal condition, it must ensue that departures therefrom called pathological can be held as of little value.

It is still generally taught that normally the chorial villi enter the utricular glands, and thereby there is formed a comparatively firm attachment between the ovum and the uterus. This error is repeated, and usually illustrated, in most obstetrical text-books, and yet it has been over and over demonstrated that the villi are larger than the mouths of the ducts they are supposed to enter, and that the relation is one of simple contact. Belief in such teachings would necessarily modify and possibly lead to wrong deductions in the study of abnormal conditions of the chorial villi.

Professor Ercolani has rendered a service to the profession of incalculable value in his studies of placental development, and his demonstrations, after long and careful research in the large field of comparative as well as human anatomy, are of the first importance to science. He shows conclusively that fetal alimentation in all mammals is carried on by a single universal law of physiological modality, that the fetal villus is simply a means of absorption of nutritive material, which is, in all cases, furnished by a glandular secreting organ of maternal development. The expression of this anatomical type is of the widest variety, and in woman, in the fully developed placenta, reaches a complexity of form confusing in the highest degree.

Charpentier* recognizes the confused and inaccurate opinions which have been hitherto held concerning the anatomical structure and development of the placenta as the chief cause of the doubts and uncertainties which pertain to its pathology; and, if this is true, it must follow that the very basis of pathological study is wanting. We can not intelligently observe the morbid changes which often ensue until we shall have satisfied ourselves in reference to a correct anatomy and physiology of the organ, and then we find, even in these pathological departures, further proof of the correctness of the observations made upon the normal conditions of evolution. However, with this key to their better understanding, numerous and serious difficulties beset the investigator, and render the task one by no means of light fulfillment.

The different affections are found united in the various constituent elements of the placenta, or, rather, those which are found in one portion of the organ are different, either in their character or degree, from the changes in other portions. Oftener these diseases attack the maternal placenta simultaneously without our being able to establish any well-marked relation between them; as, for example, a disease of the parenchyma of the villi may be complicated with an entirely different affection of the glandular organ which envelops them. Again, the same lesions, well characterized, take on diverse appearances, and produce different results, according as the pathological changes have affected the portions of the placenta depending upon the period of initiation of the process in its relation to that of evolution. It will be easily understood how the fibrous changes in the maternal placenta must present various appearances dependent upon the period of development.

The chorial villi, which during the earlier months of pregnancy are developed over the whole surface of the chorion, are all composed of two parts—internal and external. The first, which was called by Robin chorial tissue, and by Virchow mucous or myxoma, is in direct contact with the chorion; the latter, which consists of an epithelial envelope, entirely surrounds it. The villi at the placental site increase normally in number and volume. Elsewhere they are arrested in their growth, and disappear by atrophy and fatty degeneration.

The decidua is at first a single bed of cells of new formation, and afterward proliferates to a remarkable degree at the placental site—the decidua serotina. The epithelial covering of the placental villi is perceived some time after they have been enveloped by the cells of the serotina, but disappears at an early period. Not seldom, in case of so-called mole pregnancy, the chorial villi, which should atrophy, increase in volume. Under these conditions the external epithelium does not atrophy, but proliferates, and has been mistaken for the internal surface of the epithelium furnished to the placental villi from the modified cells of the serotina.

At the later stages of pregnancy the examination of any remaining chorial villi shows them still covered with an epithelial layer, while the placental villi have lost this envelope and are formed only of the fundamental myxomatous tissue which incloses the fetal vessels, and thus the external parenchyma of the villi is in contact with the internal epithelium of the surrounding maternal glandular organ.

Virchow was the first to observe that the parenchyma of the chorial villi (called endochorion to distinguish it from the exterior epithelial layer, which, from its supposed relationship, was termed exochorion) is formed of mucous tissue, which is found in abundance in the embryo during the

* "Maladies du placenta et de ses membranes," Paris, 1869.
earlier period of gestation. This tissue has the physical characteristics of mucous; chemical analysis has shown it to contain mucin; it is composed of a fluid stroma in which cells are suspended. This distinguished observer supposed that the hypertrophy of the chorial villi so frequent in abortion was caused by an increase of this tissue, and, when seen in a marked degree, there was produced the pathological condition called by Weid and Robin "dropsy of the villi," or the hydatid placenta of earlier authors.

Thus the two diseases, hypertrophied villi and hydatid placenta, were supposed to be different degrees of an exaggerated development of the fundamental tissue which constitutes the villi. Virchow agreed with Weid and Robin as to the location of the pathological changes, but included both under the term myxoma of the chorial villi.

The chorial villus may, by careful examination, be traced to its origin from the external surface of the chorion with which it is in close relation. It divides into three or four branches, and subdivides until the extremities are very thin, with their ends a little swollen, two or three times the diameter of its branch. These, microscopically, may be distinguished as formed of two parts, united yet distinct—an external epithelial layer, and the stroma or internal homogeneous embryonal tissue. Ercolani states that, if examined when the process of proliferation is yet active, it is easy to determine that they are developed from the external epithelial layer. H. Müller, in 1843, expressed the opinion that the pathological changes always began in the external envelope, and that afterward the endochorion was involved. We may also observe that the surface of the small pyriform portions which represent in the developing state the pedicellated vesicle of the hydatid placenta produces others equally pedicellated, a few of which show a small cavity in their interior. These observations, which may be easily verified, demonstrate the error in the teachings of Müller and Virchow.

The internal substance of the villi can not penetrate by pedicles, as Müller supposed, and thus, in an unknown manner, envelop the globular portion of the pyriform appendages and furnish to them the external fibrous membrane, when the fluid which they contain changes into cysts. The hyaline liquid contained therein would seem to have nothing in common with the embryonal tissue of the stroma. The changes in and destruction of the cells of the deeper layers of the vesicles explain not only the increase in volume, but also the constant property of the fluid contained in them.

Ercolani states: "If these observations are interesting in regard to the anatomical knowledge of the placenta or hydatid mole, they will be equally of profit to the histologist, who will thus be able to establish a new scientific fact, viz., the progressive metamorphosis of the external epithelial layers at the same time with the retrogressive metamorphosis of the internal layer." The conclusions of Müller and Virchow may be affirmed, that the chorial hydatid or mole of pregnancy has its origin in the epithelium covering the villi, but that the parenchyma does not aid in the formation either of the external membrane of the cyst or of the liquid which it contains.

The study of the hydatid placenta has occupied the attention of medical men since the days of Aristotle. The one fact made most apparent by the examination of all writers is their disagreement. Virchow recognized the cause of these contradictions in the imperfect knowledge pertaining to the formation or histology of the chorial villi. He teaches the identity between the chorial and placental villi, and thus himself is led into error. Myxoma of the villi, after it has reached the stage called placental, constitutes a mass more or less considerable, not seldom several quarts, of pedicellated, grape-like vesicles, varying in size and shape from a very small granule to that of a hazel-nut or pigeon's egg. There is no regular order of gradation; even the terminal ones may be the larger. The vesicles are filled with a colorless, slightly gluey liquid, which contains albumin.

The origin of the vesicles and their structure are still questions the solution of which is surrounded with many difficulties. From Virchow we learn that Rayer attributed the development of the vesicles to changes which had taken place in the vessels. After a better understanding of the parenchyma became known, it appears that Grashuis believed that the cell-tissue of the parenchyma was the origin of the vesicles, a degeneration of the trunk of the tuft, or of its coverings. Velpeau seems to be the first who decidedly opposed the theory of vascular changes, and it did not appear to him that the vesicles were, in the ordinary sense, small cysts, but that the substance of the tufts was more like a sponge filled with fluid.

Joh. Müller declared that he had found them to be not cysts, but solid swellings of the tufts. Gierse and H. Meckel believed not only that the tufts were hypertrophied, but that this hypertrophy was complicated with edema not unlike the ordinary edema of anasarca.

Mettelheimer, on the contrary, attributed the beginning of the hydatid to a transformation of the cells within the tufts changing them into cysts, and in the outgrowths of these he saw the reason for their later grape-like formation. Paget accepted this view. Virchow declares: "Increase of the epithelium, which Heinrich Müller regarded as a beginning of cyst formation, I found to be the rule in normal as well as pathological growths. It is followed, after a time, by the bud-like development of the parenchyma. But only in the parenchyma, and not in the epithelium, does the especial change take place which leads to mole formation." According to Virchow, then, the process of development in all cases is an irritative one, with an increase of cells and nuclei. The cells which he has described as "physalides" are very commonly met with, but Schroeder van der Kolk has emphasized the fact that this character of cell is often found elsewhere, and Grailly Hewitt believes the real increase in size takes place independent of these cells. It is clear that in the degeneration of the chorial villi vascularization of the tufts is generally wanting. This may be taken as evidence that the pathological changes have their initiation before the development of the capillary loops of the villi, but it is true that vessels are generally present when the disease takes place in a later period of pregnancy.

Grailly Hewitt accepts the view of Aristotle, that more commonly the fetus dies first, and certain developmental
changes occur, possibly, for months after. Such opinions are easy to demonstrate as fact, and teach a blind recognition of the maternal portion of the placenta and its relations with the fetal villi. I have frequently observed, microscopically, demonstrative evidence of the close contact of the chorial villi with the epithelial covering of the maternal vessels when the placenta has been undisturbed in its connection with the uterus for a considerable period after the death of the fetus. The chorial villi have become shrunken, and are easily separated from the decidual sheath, the cells of which have undergone active proliferation. In one instance this was observed to have taken place, and continued in a stage of active development in a portion of a placenta removed three months after the expulsion of the fetus.

That certain conditions of the uterus itself act as causes of hydatidiform degeneration would appear probable from the fact that many women are delivered of hydatidiform degenerated placentas in several successive pregnancies. Here the inference is clear that the initiating process is maternal and not fetal, and, if this be correct, it would be idle to seek in a single cause (myxomatous degeneration of the fetal villi, as Virchow would have us believe) for the explanation of all varieties of hydatidiform placenta. In this class of cases it may also be shown that the initiation of the pathological processes occurred only after the placenta had commenced its developmental changes. This is in contrast with the processes of pathological type which we have shown pertain to the so-called mole pregnancy, and which have their seat in the shaggy coat of the chorial villi when the maternal placenta is yet represented only by the decidua.

Ercolani states that "some have referred the observations made upon the hypertrophied chorial villi to the normal placental villi, while others have made the opposite mistake by referring the observations made upon these last to the hydatid placenta." . . . "There is no necessity of confounding, as has been done hitherto, the external epithelium of the healthy or diseased chorial villi with the external envelope of the placental villi, arising from the cells of the serotina."

When we consider that, histologically, the cells of the serotina form villi of secretion, and that in the human species the wide departure in their form from the fetal villi lies in the fact of their becoming dilated into thin-walled pouches, which introduct and receive into intimate union the chorial villi, it is a most interesting question to propound whether these, by any pathological change, can assume an hydatid form. Since the knowledge of the earlier writers was so inexact, their opinions must be regarded as of little value.

Depaul published, in 1868, an observation where the vesicles were in relation with the internal wall of the decidua. Martin, in one case, found vesicles upon the surface as well as in the interior of a very large placenta.

Pelvet examined an hydatid mole still shut up in the uterus, and maintained that the vesicles were attached at their extremities to the internal uterine wall. Ancelet, who quotes these observations, states that the vesicles hung suspended in the uterine cavity, detached from a membrane which clothed both the wall of the uterus and the membrane of the ovum. His explanation, that the liquid secreted by the utricular glands pushed before it the decidua layer, although a wrong interpretation, does not controvert the fact he observed, and it is beyond doubt that vesicular clusters are suspended in the interior of the uterus, and that they originate from a membrane adherent to the uterine surface.

A most interesting specimen was exhibited in the pathological collection specially arranged in London at the International Medical Congress of 1881, which I carefully examined. The patient had for quite a little period suffered from uterine hemorrhage, and the physician in attendance injected persulphate of iron into the uterus. Death followed very speedily. The autopsy showed that the iron had penetrated through the uterine walls into the abdominal cavity, and seemingly by openings into which vesicular hydatids had penetrated. They certainly appeared to occupy the uterine sinuses.

It must be assumed, as within demonstration, that the epithelium which always pertains to the maternal villi, although wanting to the fetal villi, after the very early stages of placental development, is subject to the same laws of pathological modification as belong to the choridal villi, and that certain forms of hydatid placenta may, and doubtless often do, have their departure from the cells of the serotina.

THE PATHOLOGY OF ACUTE LOBAR PNEUMONIA.

From a New Standpoint.

By WILLIAM D. SCHUYLER, M. D.

Third Article.

A Dysnomo-physico-physiological Disease.—Its Pathogenesis.—Its Functional Pathology.

(Concluded from page 879.)

The causes of what may be designated as the special asthenia of pneumonia are: In the early stages, an exaggerated waste of energy in the sthenic reactions organically developed to overcome the pulmonary circulatory obstruction, and an equal waste of energy in the local morbid pressure and counter-pressure set up. Imperfect nutrition
and the depressed nervous action alluded to contribute to produce early exhaustion. Fever, according to its degree and continuance, promotes asthenia. And, lastly, a special cause for exhaustion is the great destruction of blood which occurs through exudation and extravasation, which, as we shall see, amounts in many cases to from one fifth to one fourth, or a large proportion of the entire blood of the body.

The dangers which arise in the course of this pathological process are worthy of special mention. While they are of the gravest importance, often occasioning death suddenly, if not unexpectedly, they do not, as we shall see, result directly from the process itself, but are due to its indirect or secondary effects. They are functional, and occur through stress of necessary but generally exaggerated functional action. Dangers may arise at any stage of the malady, but are more frequent in the earlier or later periods. The early dangers grow out of interference with the respiratory function and the pulmonary insufficiency induced. The late dangers result more frequently from insufficiency of some part of the circulatory apparatus, especially of the right heart. Asthenia may also lead to general circulatory insufficiency, shown most in the peripheral circulation.

In regard to general pathology we may say: No malady presents a greater diversity or a more varied outline of symptoms than acute pneumonia. This fact of diverse expression is true of every manifestation of the disease, both as regards the extent of the local development and every constitutional symptom. Of the latter, although they form a characteristic and strongly marked group, yet any one, even the most characteristic, may be absent, or present only as a slight expression. This is true of the occurrence of malaise, of the chill, febrile manifestation, dyspnea, cough, sputa, pain in the side, etc. In some cases there is so little constitutional disturbance that the patient may scarcely recognize he is ill. These constitute, as I understand, the walking cases of Professor Flint. "The only constant element of the malady is the anatomical change in the lungs, which can be discovered only by a careful physical examination" (Jürgensen). Which statement, being true, constitutes a most significant fact for consideration relative to the essential element and factor in the disease, and particularly so coming from the author cited, who is a most pronounced and emphatic advocate of the constitutional infectious theory as the only hypothesis for its genesis.

The onset of an attack of sporadic acute lobar pneumonia, such as we are studying, may be gradual, but is quite if not more likely to be acute, in which the patient is suddenly taken, struck as by accident. There is generally a sharp chill, though this symptom, like all others, as stated, is not constant; it may be short, half an hour to two hours in duration, or much more prolonged, running over one or two days. Vomiting may occur instead of the chill in young subjects. In a typical case, following the chill there is a rapid accession of fever, denoted by a temperature rise that is quite pathognomonic; there is pain or discomfort in the chest; cough; mucous-hemorrhagic sputa; dyspnea, with greatly accelerated respiratory movements. The position of the patient at this time is sitting or partly raised; or, if lying, the decubitus is on the affected side; his countenance is anxious and cyanotic; he speaks with difficulty and in jerky sentences. By the position taken he seeks to favor respiratory action and repress the movements of the chest. He has no appetite, his bowels are inactive, and his urine is scanty, but very high-colored.

The physical signs which denote the only constant element in pneumonia may be recognized, in part, very soon after the occurrence of the chill; or they may be delayed especially those signs which are most characteristic, for several hours, a day, or even longer. Their occurrence depends upon the rapidity of the formation of the local process; and, as we shall see, when we come to the study of morbid anatomy, its development varies with every possible shade and degree of difference in different cases. Complete consolidation, with which development ceases, may be perfect in twelve hours, or it may require several days. Hence the varying time of its different expressions.

Generally anæsthesia, made with due care soon after the chill, and possibly just prior to it, will reveal at the affected point diminished intensity of the respiratory sounds, especially of the inspiratory, while the expiratory will probably be found prolonged and slightly bronchial in character. Again, respiration may be somewhat harsher in character than normal in the affected locality, throughout which there may also be heard scattered subcrepitant râles. The voice-sounds will probably be somewhat exaggerated. Percussion may or may not elicit dullness, according to the depth of the lesion and the condition of the superimposed lung-structure. After the first twelve hours, however, or at some period up to the end of the second or third day, the characteristic and clearly pathognomonic signs, consisting of more or less complete absence of the vesicular respiratory murmur, dullness on percussion, bronchophony, bronchial breathing, and possibly subcrepitant râles, will be obtained. A crepitant râle is held, generally, to be diagnostic. Although this sign occurs, most probably, in the course of every consolidation, yet, as for natural reasons it may be absent in any one case at the time examination is made, I consider it as of less value in a diagnostic sense than bronchial breathing, which symptom is constant, and its characters are most striking; especially are its tubular metallic note, its diffuseness, and its seeming, almost startling, nearness to the applied ear. The presence of this tubular breathing, developed recently over a limited or more extensive but connected area of the chest, concurring with the group of constitutional symptoms referred to, makes a diagnosis of pneumonia most certain.

The general symptoms, once developed, continue, possibly in a lessened degree, possibly increasing in gravity, up to the fifth, the seventh day of the malady, or later, when, in a large proportion of cases, they suddenly abate. The respiratory movements now become quite normal; the pulse diminishes in frequency, possibly from one hundred and twenty, or thereabouts, to one hundred, eighty, or even sixty; the temperature falls to normal or below; the mind appears relieved, the countenance brightens, and the patient, for whom much anxiety was entertained on account of the growing gravity of his symptoms, now expresses himself as
well. These striking phenomena combine to make up what is recognized as the crisis of the malady. Its occurrence indicates that resolution is going on rapidly, and is somewhat advanced; also that the functions which have been inhibited or greatly taxed are being normally resumed. Where degeneration and softening of the exudate for any cause are slow, this striking change does not occur, and resolution is said then to be by lysis. The former, by crisis, is the more natural, or frequent, mode of resolution in typical cases.

Previous to crisis, for a few hours or a day or more, physical examination will detect a resolvent action going on; bronchial breathing will have become less perfect, less metallic, softer; and developing râles, at first fine, then coarser, and of all grades—the rôle redux of this malady—will be heard. Again, just prior to crisis, the constitutional symptoms may become aggravated and more grave, but afterward, as stated, they singularly abate with its occurrence.

The various symptoms, their cause and importance, or sequence, including especial consideration for the cause of fever, of dyspnoea, and the frequency of the respiratory movements, recession of fever, especially its marked defervescence, including, also, the entire phenomena of crisis, and a general descriptive course of the disease, will be given, as stated, in a section on "symptoms and course." The different terminations of the malady will be referred to in order.

Convalescence from pneumonia is generally rapid, though in many cases, on account of asthenia, predisposing and resulting, it may be prolonged. In from two to four weeks a patient may be permitted with safety to resume his vocation. One attack of pneumonia predisposes through local delicacy to a second; therefore, prudence dictates that time be given for complete recovery.

As has been claimed, to the formation of the local process, an obstrucive, physical cause, are the pathological results noted to be attributed: The obstruction of the systemic blood, the consequent local filling of the afferent vessels, damming and setting back of the blood, due also to its continued influx, the cyanosis, stress upon the vessels within the lung, and particularly upon the right heart, the mental condition, delirium, etc., from the presence of carbonized blood in the cerebral vessels, the respiratory difficulties which occur, imperfect nutrition and early exhaustion, and particularly cardiac exhaustion—all result from the obstruction of the great, concentrated circulating current of blood by the local process.

Furthermore, as we shall see, the self-limitation of the malady is the result of the physico-anatomical events as they occur in turn, in the order of cause and sequence from the initial lesion, and govern physiological action; and lastly, as we shall further point out, it will be seen that an abatement of every constitutional symptom is due to the histological changes which occur in the rapidly degenerating exudate, as such results mechanically relieve the two functions, circulation and respiration, which its presence has so seriously inhibited. As I have shown it to be, and shall further trace, the cause of the characteristic symptoms of this malady is the obstruction of the systemic blood in the lungs; and the cause, on the contrary, of their cessation is found in the removal of this obstruction.

A CASE OF
POISONING BY SULPHATE OF IRON.*

By LUCY M. HALL, M.D.,
RESIDENT PHYSICIAN TO THE REFORATORY PRISON FOR WOMEN, HERBORN, MASS.

S. B., aged forty, born in Ireland, single, was committed to the prison for larceny in June, 1882. She was of medium size, and thin in flesh; her circulation was very active, and her general health was good, but her mind was greatly disturbed. She did not eat or sleep well after her commitment. During the third week she complained of diarrhea.

July 24th.—She was admitted to the hospital for diarrhea, accompanied by nausea and vomiting, with severe pain in the abdomen. As bowel affections of various kinds were prevalent at the time in the prison, no especial importance was, at first, attached to this case. Examination of the discharges, on the day following admission, revealed the fact that they emitted not the slightest facial odor; they were greenish in color, and of watery consistence. The breath was cold; the tongue slightly furred, pale, and cool; the mouth was dry, and imparted a peculiar, glassy feeling to the touch. The temperature under the tongue was 95° Fahr., in the vagina 99°; the pulse was weak and irregular, 100 to 108. There was extreme nausea, and efforts at vomiting were frequent; there also was severe pain in the abdomen, culminating in the rectum, with tenderness on pressure, most marked over the sigmoid flexure of the colon.

Poisoning (intentional) by sulphate of iron was suspected, but was stoutly denied by the patient. Sublimate of bismuth and tincture of opium were injected into the rectum with a little warm water; a hypodermic injection of sulphate of morphine was made over the point of greatest pain; hot flaxseed poultices were applied over the bowels. Sixteen grammes of castor-oil, with six of laudanum, had been given before the patient was removed to the hospital.

The history of the four days next following presents but little variation. Nothing was retained by the stomach except at one time a little brandy and water.

30th.—The pulse was feeble and irregular, 104 to 108; the temperature under the tongue, 96-5°. The tongue was still cool, and now thickly furred. The mouth still presented a dry, cold, glassy feel. Pain and tenderness in the abdomen was undiminished. The hypogastrium was hard and inelastic on palpation; there was no tympanitis. One flaky, dark brown discharge took place, very slightly fecal in odor.

31st.—There was a small watery stool containing black specks and flakes; odor as before. There was a discharge of bright red blood from the uterus. The last menstrual period occurred eleven days previously; menstruation had always been regular.

August 1st.—She slept a little for the first time since admission. Pulse 110, weak and running. Patient perspired freely; vomited frequently a strong acid, colorless fluid. There was retention of urine. The skin was bathed in hot water, to which a little dilute sulphuric acid had been added. A catheter was used, and 150 c.c. of urine were drawn. Its specific gravity was 1-025, its reaction was slightly alkaline, and it was heavily loaded with phosphates.

2d.—The abdomen was greatly distended below the umbili-

HALL: POISONING BY SULPHATE OF IRON.

CUS; the epigastrium was retracted. There was a dry brown stripe in the central line of the tongue; pulse 96, temperature normal. Ice-bags were applied to the abdomen, with some relief to the pain.

3d.—She complained of pain in the stomach for the first time. No medicine nor food was retained upon the stomach. The urine was scanty and high-colored. 3.15 p.m.: A copious discharge from the bowels occurred without the knowledge or control of the patient. It was fluid, containing floating specks of semi-solid matter fecal in odor; reaction neutral. The patient was greatly excited. A nourishing enema was given and retained, pressure being made upon the anus for one hour.

6th.—The patient slept a little during the night. The left side of hypogastrum was more distended than the right, was painful, tender and indurated, and dull on percussion. All substances were immediately rejected by the stomach.

7th.—The tongue was brown and dry in the center, and thickly furred. The patient seemed more ill than upon any previous day. She had no control over the discharges from the bowels or bladder. She passed large liquid stools, containing a greenish-black, finely divided, flaky substance.

8th.—The pulse was weak, 120; the temperature, 97.4°. The abdomen was less distended; there were great pain and soreness in the region of the stomach. The surface of the body was very cool to the touch. The color and odor of the breath was strongly fecal. At 7.45 p.m. the patient vomited a dark, greenish-black fluid, containing black specks almost identical in odor and appearance with those in the discharge from the bowels. Frequent vomiting (fetal), and involuntary movements from the bowels occurred till 10 p.m. Copious draughts of hot water containing a small amount of bicarbonate of soda were given; also an enema of oil of turpentine, 1 grm., warm water, 60 grm. (The latter returned accompanied by much flatus.) The patient was weak and nauseated during the night. She retained a little brandy and white of egg given by the stomach; also a portion of the nourishing enemata administered every six hours was retained.

13th.—She acknowledged having taken sulphate of iron. She said she was sent to the bath-room on July 20th, when she took a handful of the coppers used for disinfecting purposes, and chewed and swallowed it as rapidly as possible; she did not know how much she ate—probably two ounces. She soon became partially blind, deaf, and dizzy, with a sensation of numbness all over her body; her legs seemed half-paralyzed, and she could walk with difficulty. She asked to be allowed to remain in her cell, but refused to see the doctor, and was finally brought to the hospital much against her will.

14th.—She complained of a burning sensation in the stomach, more intense than at any previous time. She said her “whole insides felt sore and raw, while in the stomach a great fire seemed burning.” Pulse 80, temperature 99.6°. Tongue clean. She vomited matter fecal in odor and of acid reaction. There were frequent stools.

15th.—She was restless during the night. Her feet and legs were cold. Pulse 166, temperature 98.6°; tongue hard, brown, and dry. She vomited almost incessantly. Cracked ice, in free quantities, was given, but returned almost immediately as hot water. The epigastrium was much distended (had been retracted up to this time, so that the space between the umbilicus and the xiphoid cartilage had presented a decided concavity). Ice was applied over the stomach. Tincture of digitalis, 1 grm., and sulphate of quinine, 5 grm., were added to the enema. 8.45 p.m.: She had a severe chill.

16th.—She had no sleep; the tongue was dry; the pulse 96, temperature 99°. 3 a.m.: Stercoraceous vomiting occurred, accompanied by frequent stools. 5.30 a.m.: She vomited a bright green fluid not fecal in character. The stools were liquid, dark green, and very offensive in odor.

17th.—She was more quiet during the night. 8 a.m.: There were vomiting and purging. Pulse 112, temperature 99°. Sulphate of morphine, 0.01 grm., was given subcutaneously. The epigastrium was still much distended. There was urticaria upon the legs and body. She was very peevish and nervous. She was forcibly restrained in bed and carefully guarded. A little milk and lime-water were retained by stomach.

18th.—Pulse 102, temperature 99°. The stomach was too irritable to retain anything. Nutritive enemata were continued.

23d.—She complained of intense burning pain over the cardiac end of the stomach; the vomited matter was an acid mucous of greenish tinge; the tongue was more moist; she was menstruating. The tenderness, pain, and distension of the abdomen continued, being more marked over the sigmoid flexure of the colon. Nothing was retained by the stomach until August 27th, when a little white of egg beaten to a froth was kept, also a little beef-tea.

31st.—There was a large fluid stool containing fecal matter and shreds of intestinal mucous membrane. Intestinal glands were found under the microscope upon examination of the dejected membrane.

September 2d.—Abdominal pain was very severe. Sulphate of morphine, 0.02 grm., was administered subcutaneously. From September 2d to 6th the patient remained about the same, passing several small bloody stools and complaining of much pain.

6th.—3.30 p.m.: There were sharp cutting pains, especially referred to the old point of soreness over the sigmoid flexure, followed by a slight discharge of bright-red blood. 6 p.m.: The patient was delirious. A large quantity of blood passed, mingled with shreds of mucous membrane. Turpentine enulion, 4 grm., water, 4 grm., was thrown into the rectum, but immediately returned with a large quantity of dark blood. Ice-bags were applied to the abdomen. R. Phmb. acct., 65 grm.; accl. acet., 5 grm.; morph. acet., 0.06 grm.; aqu. pur., 130 grm. M. S. Inject into the rectum, with the hips elevated. Maintain pressure upon the anus for two hours.

7th.—No discharge from the bowels occurred after the enema of acetate of lead, etc., until 7 a.m., when the patient passed a small quantity of dark blood mingled with some of a brighter color. No further hemorrhage occurred until September 12th, when the patient had a severe chill, with a weak, rapid pulse, followed by a fecal discharge in which much dark-colored blood was clearly intermingled. The enema of acetate of lead, etc., was repeated as before. Afterward the extremities became cold, and the pulse almost imperceptible—120 to 140. Nervousness was extreme. Sulphate of quinine, 12 grm., in capsule, was retained by the stomach. Whisky, 8 grm., beef-tea, 32 grm., were administered per rectum, but returned mingled with much dark blood. All nourishment was rejected by the stomach. 6 p.m.: Exhaustion was extreme. Hemorrhage from the bowels continued. Astringent enema was repeated as above. The patient was still delicious.

13th.—There were frequent stools, but no blood. The pulse was 88, the temperature 98.6°. Bismuth subnitritat., 15 grm., opii, 0.1 grm., was ordered to be given every four hours.

15th.—6.45 a.m.: There was a large bloody stool. The pulse was 140, and very weak; the patient was flushed in the cheeks, delirious, and tooting wildly about; she was kept in bed by force; she seemed in great agony; her knees were drawn up and body bent forward. Nothing was retained upon the stomach. Sulphate of morphine, 0.06 grm.; fluid extract of hyoscyamus, 5 grm., were given per rectum, and repeated in four hours. Two hours later she fell asleep, and the respirations fell to three in the minute, but she could be roused and made
to swallow. The pulse was 90 to 108. Afterward the respirations improved, and the patient slept quietly.

18th.—Pulse 120, temperature 97.5°. A little branzy and beef-tea were retained by the stomach.

19th.—She slept more naturally than at any time during the illness.

20th.—She became very nervous at about 1.45 p.m., and complained of severe pain in the abdomen, referred especially to the former point of soreness (to the left of and below the umbilicus). A nervous chill occurred, followed by free vomiting. Her legs and feet were cold and clammy. Pulse weak, 108. Hot bottles and blankets were applied to her legs and feet. Fluid extract of hyoscymus, 0-5 grm., bromide of potassium, 2 grm., and water, 30 grm., were given per rectum. 5.30 p.m., she was more quiet.

22d.—There was incontinence of urine (constant dribbling); the bladder was found to be nearly empty.

23d.—There were four stools, in which much mucous membrane was mingled; evacuations were accompanied by excruding pains. Sublimate of bismuth, 2 grm., opium, 0-1 grm., in capsules, were given by the mouth; they were retained. 7.30 p.m.: The pulse was 120, the temperature 99-9°; the patient was delirious and excited; there was fever hemorrage from the bowels. An enema of acetate of lead, etc., was given as before.

24th.—Hemorrhage took place from the bowels. The patient was weak, nauseated, and restless. Astringent enema was repeated.

30th.—There were no further hemorrhages. She complained of much pain over the sigmoid flexure. Light fluid nourishment given by the mouth was retained.

The improvement was steady, but very slow, from this time. The abdomen remained tympanitic, the stomach irritable, and the bowels loose and irregular.

October 21st.—Great soreness in the abdomen was still complained of; respiration movements caused pain; the abdomen was swollen and tense; the iliac region especially hard and inelastic. The patient said that her bowels never felt warm and natural, but seemed like a cold, hollow tube, through which some fluid was trickling. Soft gelatin capsules passed through the alimentary canal so rapidly that they were discharged from the anus undissolved. Taking of food or drink was followed almost immediately by a discharge from the bowels, the ingesta last taken appearing in the stools.

December 10th.—Her appetite was good; the action of the bowels was irregular, but the stools were of good color and consistence. The abdomen was still tender to pressure, and of a hard, gritty feel over the lower portion. The patient was thin in flesh, but gaining daily.

In reviewing this case, the fact that at the time the poison was taken the alimentary canal was comparatively empty from previous fasting and diarrhoea should be taken into consideration, as on this account the action upon the mucous membranes by direct contact was much intensified.

The special points of interest in the case are the following:

1. The almost immediate action of the poison upon the nerve-centers, causing blindness, deafness, dizziness, numbness, and motor disturbances.
2. The length of time which elapsed after the ingestion of the poison before its action upon the intestinal canal was manifested.
3. Intense action at the sigmoid flexure.
4. The long period of inactivity of the salivary and other buccal glands.
5. Absence of pain in, and apparent contraction of, the walls of the stomach for twenty-five days after the taking of the poison, followed by acute inflammation.
6. Stimulation of the uterus (causing a return of the menstrual flow eleven days after a regular period).

A POSSIBLE RESULT OF HOT VAGINAL INJECTIONS.

By T. Naylor Bradfield, M.D., GYNAECOLOGIST TO THE WOMEN'S AND CHILDREN'S HOSPITAL, NEWARK, N. J.

A matter of much interest to me, and one which, if anywhere previously mentioned, I have failed to notice, is a possible consequence following the long, persistent use of hot-water vaginal injections.

A girl, twenty-three years of age, the subject of an hematocele extending from Douglas's cul-de-sac and above the bladder to within three inches of the umbilicus, was ordered hot carbolized-water injections, continued for an hour, and repeated no less than two or three times a day, the temperature never exceeding 100° F., or being allowed to fall below 90° F.

Six weeks succeeding the adoption of the hot vaginal injections the patient complained of increasing numbness down along the inner side of the lower limbs, with pain in the knees (notably the left), and a constant tingling of the toes, these symptoms gradually increasing until a week later, when the power to stand or walk alone was entirely lost, the patient, by great effort, being only able to hitch, or spasmodically drag her feet, when supported on either side by strong assistants.

Supposing the vaginal injections of hot water and the loss of locomotive power to have some near relation in the matter of cause and effect, the injections were discontinued for eight or ten days, with some return of strength and other decided improvements in the use of the limbs, a relapse into her former helplessness speedily following a renewal of the injections.

Dr. Thomas Addis Emmet, who had early confirmed my diagnosis of hematocele, was given a report of the case, with my views concerning the probable cause of the paralysis, which, as it appeared, was an opinion, however unreliable, somewhat original with myself. Dr. Emmet informed me that he had neither seen nor could remember any similar case, or, at least, where the use of hot-water injections had produced, or could reasonably be accused of producing, symptoms like those above described, and suggesting as a more likely cause of the paralysis the great size of the tumor, and the pressure necessarily exerted upon the pelvic vessels.

A most reasonable objection to this theory of causation (in the present case, of course) was the long time during which the patient was known to have suffered with this tumor (fully two years), and the absence of all symptoms prognostic of paralysis up to the time already mentioned, or, after the persistent use of hot vaginal injections for a period of six weeks, and when the process of softening,
together with much improvement in the circulation of the pelvic vessels, was well begun.

The adoption of hot-water injections in the treatment of pelvic diseases having become almost universal in gynecological practice, the subject to which I call attention is certainly one of interest to the profession, and may, if my views appear reasonable in the case above cited, be studied with some benefit to our patients.

Clinical Reports.

NEW YORK HOSPITAL.

TRACHEOTOMY FOR THE EXTRACTION OF A TOOTH FROM THE LEFT BRONCHUS; WITH REMARKS ON FOREIGN BODIES IN THE AIR-PASSAGES.

By Robert F. Wei, M. D.

September 13, 1883, Dr. Wei spoke as follows:

Gentlemen: The patient before us, a girl twenty-five years of age, while having a wisdom tooth extracted, two weeks ago, under the partial influence of an anesthetic, made a sudden movement which caused the dentist to lose his grasp of the tooth, and it fell down into the windpipe. Dyspnea at once supervened of quite an urgent character. The violence of the cough gradually subsided, recurring with lengthening intervals from the use of morphine subcutaneously administered. She was seen by me about a week after the accident, and the exact location of the tooth was easily determined, by auscultation, to be in the left bronchus, on a level with the sixth dorsal vertebrae, and about two inches to the left of the median line. Considerable reluctance was felt by the patient to submit to an operation, since her symptoms have not been of an urgent nature, not exceeding more than six or eight paroxysms of severe cough in twenty-four hours. There have been no signs of acute inflammation developed, though there is at times a great deal of whistling noise heard over the upper portion of the left lung, and none over the lower. This the patient is able to appreciate herself, except that while walking about it disappears. There is absence of vesicular respiration over the lower portion of the lung.

Before further considering this case, let me show you this specimen, which was obtained from a patient upon whom I was operating several years since, at St. Luke's Hospital, for necrosis of the lower jaw. During the course of the operation it was necessary to extract a tooth, and, as the patient was behaving very badly under ether, coughing and struggling, the tooth fell from the grasp of the forceps, but was supposed to have been immediately ejected during a fit of coughing. Not until two days later did symptoms manifest themselves indicating that the tooth had entered the air-passage. Dr. Leaning then diagnosed the location of the obstruction deep in the left bronchus, and the patient was advised to have it removed; but he obstinately refused to submit to an operation, and shortly afterward died of broncho-pneumonia.

In the present case, as it has been fourteen days since the accident occurred, and as there have been no signs of inflammatory reaction, you might ask, Why should we interfere? If I could feel assured that there would be no further trouble, I would not interfere. But we know, in the first place, that the tooth may become dislodged from its present location, and, by striking or lodging in the larynx, cause such spasmodic action as to imperil life; or, if it remained in situ, it would in the course of time set up inflammatory action, and thus cause a fatal termination; for you will find that, in nearly all of the cases mentioned in the literature of the subject where the foreign body has remained lodged, the patient has passed through a series of acute troubles, often terminating in consumption. Hence the result of the consultation of the surgeons to advise prompt operation.

I shall first see if the tooth can be dislodged by inverting the patient, an assistant raising her by the feet, while perpiration is made over the chest before and behind. Before doing this the patient will be etherized, and for two purposes: first, to diminish the sensitiveness of the larynx, so that, if the tooth becomes dislodged and strikes against the glottis, it will not cause so intense spasmodic action as if it were done without an anesthetic; and, secondly, so that, if it becomes necessary to perform laryngotomy or tracheotomy, the operation can be proceeded with all the more quickly. If I fail to dislodge the body, I shall have to "fish" for it, by using a homely term, by making an opening into the trachea low down, so as to get as close to it as possible, opening the lips of the tracheal wound, introducing properly curved instruments, seizing the tooth, and extracting it. Now, this is no easy thing to do, as I experienced in an analogous case the day before yesterday. A child two years of age held a coffee-bean in its mouth, suddenly drew it in, and immediately had great difficulty in breathing. It was taken to the Chambers Street Hospital, where a tracheotomy was begun; but, after the incision through the skin had been made, the breathing became so much relieved that it was supposed the obstruction had been coughed up, and the operation was not completed. When the child was transferred to this hospital, some hours later, there was some difficulty with the breathing, although not extreme. Tracheotomy was performed, but, before the trachea had been opened, the child, being under ether, suddenly ceased to breathe. This accident, I may remark, is more apt to occur in operations about the mouth or neck when an anesthetic is used. In four cases in which it has occurred in my hands, however, breathing was re-established by artificial respiration after the trachea had been opened. The patients recovered. It was so in the present instance. I was unable to detect the bean in the larynx or trachea, though the latter was carefully explored to its bifurcation. It must, therefore, have been in a bronchus. The child was sent down stairs, a large tracheotomy tube being allowed to remain in the artificial opening. In a short time word was sent up to me that the child was breathing peculiarly. I went down, withdrew the tube, drew open the edges of the wound to which threads had purposely been left, and the coffee bean popped out. In some cases the foreign body has been expelled through the artificial wound some days, or even some months, after the operation; and in some instances it has been necessary to perform tracheotomy a second or a third time.

You will now observe that the first method—inversion of the patient's body, with smart pounding on the thorax—has proved unsuccessful. Tracheotomy will therefore be performed as low as possible. For this purpose a large bottle will be placed under the patient's shoulders, in order to throw the head strongly backward and lift the larynx upward. The opening is made sufficiently ample to admit the finger, but the trachea itself is not large enough to permit its introduction as an explorer. To hold the lips of the tracheal wound apart, to afford a ready exit to the foreign body in the fits of coughing which now seize the patient, as well as to permit the easy entrance of the forceps, a silk suture is carried through a tracheal ring on each side and held by an assistant. On introducing a slender dressing forceps, bent at four inches from its end to an obtuse angle, the foreign body can just be felt at a depth of four inches and a half, with the rings of the forceps inclined to the right side—but the tooth escapes the grasp of the instrument. With a somewhat
differently bent instrument the same result ensues. A twisted copper wire, with an open loop at the end, answers no better. The loop is then bent upward, like a hook, without success. After several trials of this sort, attended, as you see, with considerable convulsive cough, it is determined not to protract too long efforts, which might end in excessive inflammatory reaction; but the use of two comparatively milder measures will be tried before abandoning surgical interference. These are to attach a number of looped threads to the end of a wire, in the hope that when introduced, one of the loops may catch on the tooth and dislodge it; and the other, which will be tried while the first is being prepared, is to pass down a long untwisted loop of slender, very flexible silver wire. Of course, with such a method you cannot feel certain whether the end of your instrument will go into the left or right bronchus. Happily, the chance is justified, for I've "caught my fish." On tightening the wire, considerable resistance is felt, so that I shall introduce on the wire, as a guide, the forceps first employed, and, as you perceive in the completion of the manoeuvre, the foreign body has luckily been extracted—not, however, by being seized by the forceps, but by the pressure of the forceps above on the wire beneath fixing it sufficiently to permit its satisfactory withdrawal. From the direction of the wire, it would seem as if the tooth had been imbedded in the anterior wall of the bronchus. The swelling of the face, which has just been noticed, is found to be due to emphysema. The cranking sensation produced by the air under the skin can be felt also in the neck and on the upper part of the thorax. This may be due to the air having been driven under the skin at the tracheal opening, or, what is more probable, to a lesion of the deeper air-passages either from my instrumental manipulation or from a laceration produced by the extraction of the tooth itself. The latter is an irregular half of the wisdom tooth. The emphysema will not require any special treatment. The tracheal opening is allowed to fall together, but the silk traction loops will be left in situ until to-morrow morning, in case it should be necessary to introduce a tube. This was found to be a wise precaution in the child's case already cited. The upper part of the skin wound will be closed with a continued catgut suture, and six layers of gauze, wrung out of hot water, will be kept over the opening and frequently changed.

Two final points I beg to call your attention to. They are the isthmus of the thyroid gland and the situation of the opening in the trachea. The thyroid isthmus, which you may have noticed at the upper limit of the incision, was very large and much distended; in fact, a slight wound of it caused quite free bleeding until controlled by a fore-pressure forceps and a catgut ligature. Usually this portion of the gland, according to my experience, and particularly so in children, can be torn through or roughly pushed out of the way without much hemorrhage. Here the contrary would have been the result. In reference to the opening in the trachea, you saw where it was when the patient was in position with the head hanging back. Now that the supporting bottle has been removed, you notice that the opening is extremely low down, so that its lower border is actually behind the sternum. In other words, the trachea was lifted nearly three quarters of an inch by the extension resorted to. Of course, the trachea is here at a considerable depth from the surface, and in this lies a danger to the patient from sinking or burrowing of matter behind the sternum—not a great one, it is true, but of some moment. She will therefore be encouraged to lie as much as possible on her side. The progress of the case will be announced to you at the next clinic.

Note.—September 25th.—The patient has passed uninterruptedly toward recovery, having only a slight bronchitis to contend with. The tracheal opening closed on the sixth day, and she is now going about the ward.
of the Larynx is by Durham, revised by Hensman. Together they cover something over two hundred pages, and include everything from Quain's to Expistaxis, from Cancer to "Annu-
ibus Migrans." We notice particularly the subjects of cleft-
palate, tumors of the jaws, leucoplakia, the table of sixty cases of removal of cancer of the tongue, and the various operations for cancer, as containing the latest information on these subjects.

The chapter on Diseases of the Intestines is by Pollock, that on Hernia by Birckett, and that on the Rectum by Henry Smith. The greater part of the former is devoted to the consideration of the subjects of intestinal obstruction, stricture, and the ex-
cision of cancer. Upon all of these questions the author is in-
clined to the safe and conservative side, and what he has writ-
ten may safely serve as a guide to the general reader. Under Hernia we observe little that is new, and Mr. Smith has, ap-
parently, been so cramped as to space that he has simply outlined the salient points in Diseases of the Rectum. The remainder of the second volume is devoted to Diseases of the Skin, which are divided into general and local. The former are treated by Jenner, Hillier, and Nayler, in 1876, and by J. S. Bristow, 1882; the sections on local diseases (corns, bunions, warts, boils, carbuncle, malignant pustule) are contributed by Thomas Smith, 1871, and Rickman J. Godlee, 1882. It would appear as though a very interesting discussion might be held upon the propriety of considering either a boil, a carbuncle, or carbuncle as a local skin afflection.

The Essentials of Pathology. By D. Tod Gilliam, M. D., Pro-

fessor of Physiology, Starling Medical College, etc. Phila-

This is a curious book. In the first place, it has a title which excites query. What is meant by "The Essentials of Pathology"? Of course, they must be the "fundamentals of pathology," mentioned by the author, but in this way one is thrown from Scylla to Charybdis, and, if, in searching for the "fundamentals," the reader does not find himself seated in the sea instead of passing safely between these portentous rocks, he will be lucky.

"Some departures from the ordinary have been made in the arrangement of the work." It may be that the author reasons well, else whence these pleasing thoughts concerning the au-
thorship of a book? The departures, however, must be in the text, and not in the illustrations, for the latter are chiefly from Riddifield, and have been taken without credit. Perhaps this is one of the "departures from the ordinary." If so, it will not
hear repetition, unless upon the ground that Riddifield is now
out of print, and it is desirable to perpetuate that author's memory. There is so much in this hook that is so nearly like what has already been published in several works which are readily accessible that the question is suggested, Why was it published? Of course, the author's shaming is evident, but it constitutes so thin a film that an adjustable objective is not re-
quired to look through the covering. But there are other curi-
osities here. For example, the author says: "Occasionally
there is a nuclear division without a corresponding division of the cell substance. The cell enlarges, however, in the same ratio of growth, and, as a consequence, there results a larger mass of protoplasm, containing many nuclei. This is known as the myeloid or giant cell." This is an astonishingly easy way, surely, to get over a mooted pathological point, and its simplicit
y would have brought blushes to the cheeks of Klebs, Köster, Hering, Treves, Lancereaux, and others who have hatted so vigorously to sustain their theories concerning the origin and mode of formation of these bodies. Possibly this is one of the

"departures from the ordinary." At the same time the review-
er is aware that the theory is supported by one able observer.

Again, in speaking of the "excudation" in the gray hepatiza-
tion of crompos pneumonia, the author says: "The epithelial
ells of the alveolar walls, which up to this time displayed only a cloudy swelling, now take on active proliferation, and add their progyny to the swelling multitude of embryonic cells which now crowd the alveolar spaces. A rapid degeneration now en-
sues." There does not seem to be very much doubt that it has
begun. At all events, there are so many of the "fundamen-
tals" of pathology imbedded in the meshes of this single sen-
tence that it can not sustain its own weight, and, consequently, degeneration or rupture is a forced condition. There is an im-
mensel amount of pathology wrapped up in this statement, but it does not seem to the reviewer that the "essentials" would have been injured by the association of less obfuscation and more perspicacity.

It must be inferred, as with reference to many other acci-
dents, that there is some valid reason for publishing this book
aside from that given by the author. Perhaps his students asked it as a special favor; but an old teacher should not have let the desire for fame blur the fact that boys are up to all sorts of pranks. However, the illustrations are not bad, because they originated with good authorities in pathology; the text is ob-
scure in many places, but perhaps no more so than in other books written to illustrate the fact that the same idea can be expressed in different ways; the paper and printing are good.

A Text-Book of General Pathological Anatomy and Pathogene-

This volume constitutes a valuable addition to those by which it has been preceded. Of course, it will not prove so in-
teresting to the general practitioner as to those specially in-
terested in pathology, but there is sufficient information in its pages that can be readily taken up by the medical man with average qualifications to make it a desirable addition to his li-
brary. The translator and editor has made many good addi-
tions, such as broaden the scope of the work as a hook of refer-
cence, and besides bring it well up to the advanced ground
which this department of medical science now occupies. Profes-
sor Ziegler is also engaged in writing the second part of this work—that on Special Pathological Anatomy—and it is to be hoped that the translator will give it his immediate attention as soon
as its publication in German has been completed. Malforma-
tions, disturbances of nutrition, inflammation and inflammatory

growth, tumors and parasites, are the subjects considered in this part, and it is fully illustrated. Professor Ziegler is a terse
writer, and seems at times to be rather dogmatic, but yet not
too much so, perhaps, to carry conviction to the mind of the
student.

OFFICIAL visitors to hospitals, and those interested in hospital
management, will find this volume of great practical service. Without encroaching too much upon the province of the archi-
tect, clear and common sense directions are given as to hospital
construction, ventilation, heating, plumbing, etc. We quote
some of these as examples: "The approved plan [of hospital
building] requires one-story wards, raised on piers or arches,
that the air may circulate freely, the ground beneath being
coated with asphalt, or other smooth, dry surface. The wards are to be built of wood where the fire laws permit, or of brick with a ‘damp course’ of slate or asphaltum.” “The hospital should never be built around a closed court. Whether it have one or more stories, the long axis of all its wards should run as nearly as possible from northeast to southwest.” “The annex containing the water-closets and other service-rooms should be built at the north end of the ward but a little to one side, so as not to interrupt the air-currents.” “It is a serious error to build wards opening directly into one another.” “The ward windows should take up one third of the wall space. The windows should be on opposite sides, at least one window between every two beds in the medical wards, and one window for each bed in the surgical wards.” But the book throughout is full of such almost epigrammatic sentences. Following the chapters upon construction we have directions as to the internal management, the laundry, the kitchen, and the nursing service. Then comes a chapter treating of village hospitals; and, finally, one full of practical detail as to the proper use of disinfectants. In the appendix a good list of authorities is given for reference. Whoever the author of the book may be, he is entitled to the highest praise for the admirable manner in which he has done his work.

This most valuable portion of this book is the second part, which gives plans and descriptions of a number of the leading hospitals of the world. The first part treats of the construction of hospitals, both general and special, and is not so good as other works we have read. Ten American hospitals are briefly described, three of which are in New York city, viz.: Bellevue, the Roosevelt, and the German Hospitals. We can but express our surprise that the New York Hospital is left entirely out. A list of the literature of hospital construction is given.

The present volume presents an appearance uniform with that of the series by which it has been preceded, and contains the papers read before the college from December, 1881, to July, 1883, inclusive.

There are thirty-one contributions, some of which are illustrated, and the range of subjects makes the volume one of the most interesting that have been published. The reviewer has been especially interested in reading the papers by Da Costa, on Catarrhal Fever; Keating, on The Presence of Micrococci in the Blood of Malignant Measles; Meigs, on Albuminuria; Roberts, on Heart-puncture and Heart-suture as Therapeutic Procedures; Wilson, on The Management of Enterie Fever; Hamilton, on Sewer Gas and its alleged Causation of Typhoid Fever; Leeds, of Hoboken, N. J., on Infant Foods; Catlin and Weir Mitchell, on The Relation of Pain to Weather; and Eskridge, on Abscess of the Brain. The paper on the question, “Does Excision of the Larynx tend to the Prolongation of Life?” by Dr. Cohen, is, from a statistical standpoint, one of the most complete and elaborate of the series. His conclusion is that excision of the larynx for carcinoma does not tend to the prolongation of life, and that the greatest good to the greatest number appears to be better secured by dependence on the palliative operation of tracheotomy. It would be inviting to enter into a somewhat detailed consideration of each of these papers, but the limits of this review preclude us from the undertaking, and we must be content with the statement that the volume is worthy of careful perusal. Many of the papers and discussions have been given in this journal.

This is a pleasant series of lectures upon nursing, the subject being treated from its medical side alone. It is not a complete treatise, but what it contains is thoroughly useful and practical. One sentence in the book might well be posted as a motto in every nurse’s room in place of the usual “Home, Sweet Home,” and that is: “Of course, as individuals you must form opinions, but as nurses you are not to act upon them; it is the doctor’s opinion you follow.” The author instructs the nurses in the important symptoms which are to be observed, such as the temperature, the pulse, the respiration, and the variations in the discharges from the body. He gives a short description of digestion, and hints as to the proper cooking and administration of food. Directions as to the proper making and application of poultices, baths, etc., are clearly and concisely given. The appendix contains recipes for food for invalids, a table of poisons and their antidotes, a schedule of weights and measures, and a glossary of medical terms.

This small book contains a few methods by which various tissues of the body may be prepared for examination with the microscope. It does not aim to be exhaustive, but it is concise, practical, and comprehensive. It is evidently the writing of one who has employed the methods recommended, and at nearly every step can be recognized readily the hand of an expert manipulator. If the student will follow exactly the directions given in the pages of this little book, he will learn much that will be of great service to him in the use of the microscope. The part in practical pathology contains but little aside from methods of sealing up specimens and staining bacteria. Under the last head have been given a variety of methods of staining the bacillus tuberculosis. About the only objection that can be urged against the book is, that there is not enough of it.

BOOKS AND PAMPHLETS RECEIVED.

LETTER FROM PHILADELPHIA.

The Health of the City.—The College of Physicians.—The Nurse Registration Bureau.—The County Medical Society and the Question of admitting Women to Membership.—Opening of the Winter Sessions at the Colleges.—The New Lunacy Law.—The Clinics at the Pennsylvania Hospital.—The Unrestricted Sale of a Poison.—Professor Goodell and the Carbonic-Acid Spray.

PHILADELPHIA, October 4, 1883.

The remarkably pleasant weather of last summer has been followed by weather equally fine, though more seasonable, thus far in the autumn, and the favorable results upon the health and happiness of the community are evident not only in the decreased death-rate, but also in the abundant leisure of physicians. It is in vain that they consult Ephemerides—a practice which we have no doubt must be very reprehensible, since Dr. Rush mentioned it only to condemn. There is no epidemic, or prospect of one; the few patients with typhoid that belong to this season of the year have had very few enteric symptoms, and, as the rule, have been more or less constipated throughout the disease; small-pox has nearly disappeared, and the other zymotic affections are similarly kept in abeyance; even consumptives are able to lead an out-door life and seek health from first sources. The doctors, therefore, having much unoccupied time on their hands, improve the occasion and attend the various medical societies which have started out with good prospects for an active winter's campaign.

The College of Physicians, which meets once a month, has within the past year shown greater activity than ever before, if the handsome annual volume of the "Transactions," which has just been issued, may be taken as any criterion. Having a membership now of over two hundred, the meetings are now well attended, new members are applying for admission, the papers and discussions are able and animated, and the library is growing at a rate which indicates the need of greater accommodations in the near future. Indeed, plans have already been drawn for building a third floor, and some steps have been taken toward obtaining the means. The Mutter Museum Committee has a large surplus in its hands, it is true, but, unfortunately, its funds can not be appropriated for this purpose without diverting them from the original object of the trust. There are signs of increasing sociability among the Fellows, and a committee has been appointed to make arrangements for receptions this winter, and possibly they may inaugurate an annual dinner.

The Nurse Registration Bureau established by the College of Physicians has been a great convenience both to physicians and to patients, and is becoming appreciated by the community. Although the fees are moderate, it has usually a surplus at the end of the year, which is given to the library of the college.

The County Medical Society, with about four hundred members, meets three times a month, and also issues a very creditable annual volume of proceedings. At its quarterly business meeting, held October 3d, the woman question was again put to the test of the ballot, but the female candidates once more failed to get the requisite two thirds of the votes. A large and exciting meeting was held, but no discussion of the merits of the question was indulged in; the right of women practitioners having been conceded by a standing resolution of the society; passed nearly two years ago, which declared women to be eligible for membership under precisely the same rules and regulations as govern the admission of men. The census recommended three ladies for membership, against whom no professional or personal objections were made, but the highest on the list received only seventy votes out of one hundred and sixty-five. Although the misogynists carried their point again, the sentiments of justice and liberality are prevailing gradually in the ranks of the members, and the question bids fair to be a perennial one, until settled in accordance with the law and usage of the American Medical Association, to which this County Medical Society is subordinate and responsible.

The Pathological, Obstetrical, and other societies are keeping well up to their work, and give no signs of degeneracy.

On October 1st the regular winter sessions were opened at both the University of Pennsylvania and the Jefferson Medical College, the introductory to the one hundred and eighteenth course of lectures at the university being delivered by Professor Alfred Stillé, that to the fifty-ninth course at the Jefferson being given by Professor Theophilus Parvin. The class at the university is larger than last year, the Freshman class in the Medical Department being over one hundred against seventy last session; the students, thus far, at Jefferson are less numerous than last year, although, owing to the different system of lecturing, the class is later in getting together.
The new insanity law went into operation September 19th, by which a committee on lunacy of the Board of Public Charities was created, with jurisdiction or "supervision over all houses or places in which any person of unsound mind is detained" for treatment. All hospitals or houses for the reception of persons of unsound mind must apply for a license to this committee, to whom detailed reports of the condition of each new patient must be sent within twenty-four hours after admission. No restriction is permitted upon the communication of such persons with their correspondents or friends, except that they may not address the committee oftener than once a month.

The committee has full power to discharge patients from such institutions, and to issue regulations for their control, to pay visits of inspection, and revoke licenses at their discretion. This committee is composed of Phillip C. Garrett, Esq., Chairman, the Hon. Henry M. Hoyt, Thomas G. Morton, M.D., E. Coppee Mitchell, Esq., W. W. H. Davis, Esq., and A. J. Ourt, Secretary.

The managers of the Pennsylvania Hospital recently done a very unwise act in placing a restriction upon clinical teaching at this celebrated institution by charging five dollars for registration and admission to the clinics. It is a step that reduces the class to about one tenth of its usual number; at present it is not more than thirty; clinical lecturing by such men as Agnew, Levis, Da Costa, Hutchinson, and the others, to such an audience is simply ridiculous. The medical staff is much exercised by the peremptory manner in which they have been set to work to earn money for the hospital; however, its their wishes were not consulted in the matter. It seems like an unpleasant precedent to establish, but the possession of power has always the tendency to make men arbitrary.

A suicide of a defaulting treasurer of a building society, by swallowing Paris green, in this city a few days ago, again directs public attention to the reckless manner in which this arsenical preparation is sold and handled. Some forms of arsenic cannot be purchased unless the druggist registers the name and address of the purchaser, and is satisfied that it is to be properly used; but Paris green can be bought by the pound at the country grocery store without any restriction.

It is said that Professor Goodell is about to give up the carbolic-acid spray; he has operated in several cases without it, and has had equally successful results as with it.

LETTER FROM ST. LOUIS.

The St. Louis Fair.—Sir William McCormack.—The Prevalence of Malarial Disease.—The Hodge Club.—The St. Louis College for Practitioners.—Ethical Matters.

St. Louis, October 5, 1883.

This is the gala week of the year in our city. The St. Louis fair has a national reputation, and during this week the hotels and boarding-houses, and all sorts of lodging places and restaurants, have been taxed to their utmost capacity in providing for the thousands of strangers who have thronged our streets to see the "procession of the veiled prophets" and to attend the fair. The weather has been unfavorable, and it will be remarkable if many do not suffer in health from exposure to wet and mud and the fatigue attendant upon the unusual excitement and exertion.

Sir William McCormack has been in the city for a few days, and some of the members of the St. Louis Medical Society gave him an informal banquet at the rooms of the Mercantile Club last Saturday evening. It was an improvisu affair, all the arrangements having been made after seven o'clock that evening. Everything passed off very pleasantly, and Sir Williamexpressed himself as much pleased with his entertainment.

The summer here has been remarkably cool one. In fact, the "Stay-at-Home Club" and the "Can't-Get-Aways" rather flirted themselves that they had a more comfortable time than the travelers this year. In fact, the last two summers have been so comfortable that our daily papers have suggested the propriety of setting forth the claims of our city as a summer health resort. At present there is a general prevalence of malarial disease, even more than is usual here at this time of the year.

A few months ago a little company of physicians organized a new medical society. Several meetings have been held, and they have been pronounced completely successful by those who have attended them. It has been the aim of its members to cultivate the social rather than the intellectual element, and to have meetings monthly or bimonthly, at which there should be opportunity for conversation and social intercourse, with a supper more or less elaborate. It is proposed now to introduce a working element, and to have discussions, perhaps papers, at each meeting. It is the intention to give some special study to matters of hygiene. All of the members of the society were more or less intimate friends of the late Dr. John T. Hodgen, and, in honor of his memory, the name selected for the organization is "The Hodgen Club."

The St. Louis College for Practitioners has just issued the announcement for its second year. It is claimed by its officers that this was the first college in the United States organized expressly for medical practitioners. Some of the members of the faculty are men of real merit and ability, but it is generally thought that these excellent men are associated, to their disadvantage, with others who are more shrewd and less scrupulous. Considerable talk has been caused by the fact that in the announcement there is a list of honorary members of the "College Association" in which appear the names of the deans of both the prominent regular medical schools, the St. Louis and the Missouri Medical Colleges, their titles as deans being given in full. It is a shrewd plan on the part of the officers of the College for Practitioners to give the impression that it is indorsed by the faculties of these other institutions. Inasmuch as this is not the case, it is expected that the gentlemen will decline the honorary membership which has been conferred upon them. (It is said that in one case the election to honorary membership was accepted, and that in the other a letter declining the same was sent after the Announcement of the College for Practitioners was out.)

Speaking of unprofessional advertising, I think the St. Louis Medical Society will have some cases of infringement of the code of ethics to take in hand at an early date. In the morning "Globe-Democrat," the leading daily paper, an advertisement occupying a third of a page has appeared, calling attention to a combination of coca and tobacco, under the name of coca-plug, stating that "coca is a great nerve tonic, and, when combined with tobacco, it counteracts the injurious effect of the nicotine upon the system, which facts are certified to by the highest medical authority." In this advertisement are included certificates from six prominent practitioners to the effect that the combination of tobacco and coca would be less injurious to the system than tobacco alone.

Certainly, if it was unprofessional for prominent New York physicians to give testimonials as to the value of Hunyadi János and Apollinaris waters, it is none the less so for St. Louis physicians to give certificates for publication in the daily papers as to the value of such a combination as that referred to.

The St. Louis Medical Society has advertised itself pretty thoroughly to the country by its action in regard to the resolution offered by Dr. Pollak at the meeting of the American Medical Association, and there is a good opportunity now to support the code of ethics in a practical manner by calling its members to account for such unprofessional certificates.
THE HYDROCHLORIC ACID OF GASTRIC DIGESTION.

The presence of free hydrochloric acid in the stomach during the process of gastric digestion is well known, and its absence in certain morbid conditions has of late years been looked upon by some German writers as of great importance. In a recent number of the "Progrès médical" Dr. E. Voght gives an interesting résumé of the views put forth by these writers.

Dr. von den Velden has tested the contents of the stomach, withdrawn during digestion by means of a Kussmaul's pump, using various reagents for the detection of free hydrochloric acid. Of these different reagents, tropeoline was found to give the best results, being a yellow substance which turns red in the presence of a mineral acid, but in which the organic acids cause no change of color.

In the case of a patient with typhoid fever, von den Velden found that the acid was absent during the whole course of the disease, but that it reappeared during convalescence. In cases of simple dilatation of the stomach the acid was never found wanting, but in those of carcinoma its presence could never be detected. The absence of the acid can not be due to debility or a cachexia, it is argued, for it persists even after the patient is much improved, and those who are in the highest degree marasmic still preserve the acid, provided they are not cancerous. And no chemical action of cancer juice can be at the bottom of a lack of the acid, for all the eight cases observed were examples of non-ulcerated scirrhus. In one instance von den Velden founded a diagnosis of cancer on the absence of the acid, in spite of the lack of any other symptom; and the autopsy proved him to have been right. On the other hand, in a case where all the symptoms pointed to cancer he denied its existence on the strength of finding the acid, and in this case, too, he was proved to be correct. In a case of cancer of the liver, without involvement of the stomach, the acid was found to be present.

Further researches by von den Velden have shown that the saliva which reaches the stomach mingled with the food acts upon the starch only when there is no free hydrochloric acid present, so that, as the acid appears in an hour or an hour and a half after eating, we may distinguish two periods of gastric digestion—one in which the saliva continues to act, and the other in which peptones are formed in large amounts.

These conclusions have been criticised violently by Ewald, who maintains that the action of the reagent may be disturbed by the presence of albuminates, blood, etc.; that in many cases of carcinoma the hydrochloric acid reaction is preserved; and that the two periods of gastric digestion have no existence, the diastatic action being only diminished, and not suppressed, when the gastric juice becomes acid. Von den Velden retorts that Ewald's chemicals (the tropeoline, etc.) were not pure, and that he did not attribute a specific action to carcinoma, but was simply seeking to ascertain in what particular cases the free acid was absent.

Dr. Edinger, having observed that the acid was absent in two cases of amyloid degeneration of the gastric mucous membrane, is disposed to attribute the fact to the existence of an endarteritis obliterans of the arteries of the mucous membrane. Proceeding on an idea of Ránauer's, he has devised an ingenious and advantageous substitute for Kussmaul's pump. A little piece of sponge, inclosed in a gelatin capsule, is swallowed by the patient, a thread having been attached to it. At the end of half an hour the sponge is withdrawn. By this time the capsule has been dissolved, and it suffices to press out the juice contained in the sponge, and test it with tropeoline.

Dr. Uffelmann, who experimented on a person with a gastric fistula, prefers methyl violet as a test for the free acid, and proposes a process based on the employment of the coloring matter of red wine. Edinger objects to this, however, and clings to the tropeoline. In nine febrile patients, Sassesky has observed that the acid disappeared when the fever was accompanied with indigestion.

It is evident that a wide and promising field for investigation has been opened by these experimenters, and it seems likely that the sponge and gelatin device may facilitate further research.

ARTIFICIAL IMPREGNATION.

We doubt if it will finally be recorded otherwise than as to the credit of the medical profession that the feeling of curiosity with which it has looked upon the experiments that have been made from time to time in artificial impregnation has always been associated with an under-current of disapproval. A pointed confirmation of our doubt is to be found in certain judicial proceedings that have lately taken place in France.

It seems that a Bordeaux physician, one Dr. de Lajartre, had advertised somewhat pompously in the newspapers that he was in possession of a peculiar and infallible means of overcoming sterility. In consequence, one Madame A. was induced to give him a method a trial. The doctor performed an "operation" upon her, but not only did it fail to accomplish the object in view, but it gave rise to a pelvic disease, if Madame A.'s account is to be credited. For these reasons, the lady and her husband declined to pay the doctor's fee, 1,500 francs. To account for his failure, and at the same time to strengthen his title to the fee, the doctor maintained that conception had really taken place, but that the lady herself willfully took measures to produce an abortion.

The matter became a public scandal, and was at last brought into court, de Lajartre having sued for his fee, and the husband and wife setting up a counter-claim for damages, founded partly on the derangement of health alleged to have been caused by the doctor's procedures, and partly on the detriment to the reputation of the pair due to his having bruited the facts about.
These circumstances were brought out in the trial of the case. De Lajartre not only lost his suit, but was compelled to pay all the costs. The judge's decision was coupled with a rebuke of the doctor's ways, and with a decided expression of opinion that such experiments as he had made use of ought not, in the interest of public morals, to be shifted from the domain of science to that of every-day life.

The justice of the decision is scarcely less evident than the propriety of the remarks with which its delivery was accompanied. This, we take it, will be conceded by the great majority of our readers, but the interesting question arises as to M. de Lajartre's status in the French profession. If his conduct is not quackery of the vilest sort, we fail to comprehend the meaning of the term; and, if his career is allowed to continue, we shall eventually begin to doubt the efficiency of the laws governing medical practice in France, and to question if "Lyon medical" might not profitably devote to the consideration of such matters a medium of the space it lately allowed one of its correspondents, a M. Poncet, in which to enlarge upon his discovery that Americans do not eat, but simply stuff themselves.

THE ILLINOIS STATE BOARD OF HEALTH.

By the board's latest publication, entitled "Medical Education and the Regulation of the Practice of Medicine in the United States and Canada," we learn with much satisfaction that there are no signs of its receding from the stand it has taken in the matter of the "good standing" of medical colleges. A list is given of twenty-four institutions which the board declines to recognize, and it is stated that there are several others concerning the status of which the board has not yet been called upon to decide. It is suggested, however—and herein lies the specific pledge that the board will not recede from its position—that the standing of any medical college may be readily determined, for the purposes of the Illinois Medical Practice Act, by comparing its curriculum and requirements with the schedule set forth by the board some time ago, which schedule is now published again; and the hint is given that students intending to practice in Illinois will do well to make the comparison for themselves if they wish to avoid an examination by the board.

It is further stated that the Illinois requirements have been adopted by the Missouri State Board of Health, and that they will soon be adopted by the Minnesota State Board of Medical Examiners. There are several other States, notably that of West Virginia, in which tantamount requirements are in force, and it is continually growing more and more intolerable that the older and more populous States of the east can not be shamed into a like policy.

THE AMERICAN ACADEMY OF MEDICINE.

Elsewhere in this number of the journal will be found an abstract of the proceedings of the Academy at its eighth annual meeting, held in New York on Tuesday and Wednesday of this week. It will be seen that several well-known members of the profession were in attendance, and that some of the papers read were of more than ordinary importance. The meeting must be classed as one of the most successful in the short history of the Academy, not only for these reasons, but because among the gentlemen newly admitted to membership there were some who will undoubtedly add an element of positive strength to the organization.

The particular aim of the Academy, as many of our readers are doubtless aware, is to raise the standard of medical education in this country, and thus far the most noticeable feature in its plan for attaining that end has been to restrict its membership to those who have an academic degree. In so doing, the Academy concentrates its energies on the single point of preliminary education. By reason of that fixity of purpose, it ought to be able to accomplish something tangible before many more years have passed. It seems to us that there are two ways in which the Academy might have set about its work: one by dwelling on the advantages of the sort of preliminary education it favors, and the other by devoting itself to the task of bringing out a class of papers and discussions that should, by their manifest superiority to ordinary society work, demonstrate the strength of its doctrine without directly alluding to it. It has chosen the former course. Whether it would not, even now, be the part of wisdom for it to shift to the latter is a question that, it seems to us, may fairly arise in view of the slight impression it has thus far made upon the profession.

MINOR PARAGRAPHS.

THE HEMERALOPHIA OF THE TROPICS.

Under the term "essential hemeralopia," M. Fontan has described, in the "Receuil d'ophtalmologie," a visual trouble, characterized mainly by nocturnal amblyopia, which has generally been considered as independent of any permanent and definite disease of the fundus of the eye. He excludes from consideration the hemeralopia which is symptomatic of retinitis pigmentosa, and also that which sometimes appears in certain forms of papillary atrophy and chronic choroiditis. This nocturnal amblyopia is met with as an epidemic in groups of cases or in isolated cases in tropical countries. As regards its aetiology, he thinks that sudden alterations in the degree of illumination are more likely to act as an exciting cause than a continuous bright light. Any debilitating influence and certain general morbid diseases—such as paludism and melanemia—act as predisposing causes. There is no intimate connection between scurvy and this affection. The paludal influence is met with at every step in nautical or tropical hemeralopia.

The form of hemeralopia in question is accompanied by an habitual dilatation of the pupil, a diminution of the range of accommodation, sometimes a concentric limitation of the visual field, dyschromatopsia, and certain ophthalmoscopic lesions which are almost constant. The paresis of accommodation is analogous to senile presbyopia, but its cause is not to be sought for in loss of elasticity of the lens, but in weakness of the ciliary muscle. The limitation of the visual field is by no means constant. Among the ophthalmoscopic lesions, the most marked is the white, amnic aspect of the papilla and its immediate surroundings. The veins are large, engorged, and of a violet or chocolate color. The arteries are bifid, and often invisible. The circum-papillary serous effusion appears like a thin, pale-rose or whitish cloud, semi-transparent, and of ill-defined limits, which rarely surrounds the papilla entirely. These changes all
DYSENTERY IN BUFFALO.

An editorial writer in the "Medicinisch-chirurgisches Correspondenz-Blatt," a monthly journal published in Buffalo, states that dysentery in endemic in East Buffalo, where there is no systematic drainage. Out of about fifty cases, the writer has had no death is an adult or in children past the tender age. He admits that the disease may be unusually mild, but avers that every case has been typical. The treatment he has employed is as follows: At first a powder is given containing from twelve to fourteen grains of calomel, half a grain of resin of podophyllum, a tenth of a grain of morphine, and four grains of sugar. After four or five evacuations have been produced, the patient is to take, every three hours, a pill containing a sixth of a grain of opium, two grains of salicylic acid, a quarter of a grain of acetate of lead, and a grain of powdered ipecac—taking twelve pills in all. If this does not succeed, both the powder and the pills are repeated. The statement is made that no other measures were found to be of service.

THE AMERICAN CLIMATOLOGICAL ASSOCIATION.

We lately mentioned a movement for the organization of a society for the study of climatology in its relations to medicine. We now learn that, at a meeting held on the 25th of September, an association was formed under the name that heads this article, and that it was determined that its objects should be the study of diseases of the respiratory organs, together with the influence of climate thereon. The following-named gentlemen were elected officers: Dr. Alfred L. Loomis, of New York, President; Dr. Frederick I. Knight, of Boston, First Vice-President; Dr. W. H. Geddings, of Aiken, S. C., Second Vice-President; and Dr. James B. Walker, of Philadelphia, Secretary and Treasurer. We are informed that it is intended to hold the first annual meeting in Washington at about the time of the meeting of the American Medical Association. Forty gentlemen in different parts of the country are said to have accepted membership.

COPPER AS A PREVENTIVE OF CHOLERA.

It seems that M. Burq was mistaken when he lately supported his theory of the preventive action of copper against cholera by citing certain alleged observations by M. Vulpin in India and China, to the effect that the army officers serving in those countries found the metal an effectual protection. M. Vulpin states that he had never even heard of its being resort to for that purpose until he read an article in a secular paper crediting him with the experience alluded to. He regards the notion as chimerical, but sees no objection to a cautious use of copper for the purpose of settling the question.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 9, 1883:

YELLOW FEVER.—During the week news has been received of terrible ravages by the disease in various parts of Mexico, and refugees are arriving in New Mexico. All danger to San Francisco from the steamer that lately arrived there with yellow-fever patients on board is thought to have ceased, and most of the passengers have been allowed to land. Several doubtful cases are reported from Brewton, Ala., where two deaths have occurred, but the opinion prevails among the physicians of the locality that the affection is hemorrhagic malarial fever, and the President of the Pensacola Board of Health assures the Surgeon-General of the Marine-Hospital Service that there is no yellow fever at Brewton. Several cases supposed to be yellow fever have appeared at Torre Annunciata, near Naples.

ST. BARTHOLOMEW'S HOSPITAL, LONDON.—Dr. Norman Moore has been elected an assistant physician.

CHOLERA IN IRELAND.—A correspondent of the "Lancet" reports what he considers to be genuine cases of Asiatic cholera as having recently been observed at Sligo.

AN ATTACK ON A PHYSICIAN.—M. Rochard, medical inspector-general in the French navy, was recently shot in the chest by an unknown assailant while returning to his house in Paris from a call at the department. At last accounts, he was reported to be doing well.

DISEASES OF DOMESTIC ANIMALS.—Infectious pleuro-pneumonia is reported to have broken out among the cattle of Lehigh County, Pa.

DIPHTHERIA IN AN INFANT ASYLUM.—Several cases of diphtheria having lately occurred in the country branch of the New York Infant Asylum, at Mount Vernon, the East Chester Board of Health proposes to investigate the sanitary condition of the premises.

INSANITARY SCHOOL-HOUSES.—A complaint having been made of the unwholesome condition of grammar school No. 69, in West Fifty-fourth Street, an official of the Board of Health has reported that the drainage is radically defective, both in the traps and in the air-inlets. The proper recommendations have been made. Like defects of plumbing have been found in grammar school No. 32, in West Thirty-fifth Street.

THE GARFIELD MEMORIAL HOSPITAL.—It is announced that work was actually begun on the buildings last week.

"FORT MIT DEM ESZLÖFFEL" is the cry of a writer in the "Deutsche Medizin-Zeitung" pleading for the use of the metric system.

THE "MEDICAL WORLD" is the title of a new weekly journal published in Philadelphia. It is edited by C. F. Taylor, M. D. The first number, dated September 27, 1883, is accompanied by a lithographic portrait of Professor Austin Flint, Sr., in the form of a supplement.

THE SISTERS' HOSPITAL, BUFFALO.—Dr. W. S. Tremaine, of the army, professor of surgery in the Medical Department of the University of Niagara, has been appointed surgeon to the hospital, and will hold two clinics each week.

OBITUARY NOTES.

SHERIDAN-GENERAL CRANE, OF THE ARMY.—A brief dispatch from Washington, received on Wednesday, conveyed the sad information that the Surgeon-General died in Washington on the morning of that day. Subsequent dispatches to the

LETTERS TO THE EDITOR.

THE PROPOSED AMENDMENTS TO THE CONSTITUTION AND BY-LAWS OF THE ACADEMY OF MEDICINE.

To the Editor of the New York Medical Journal:

Sir: The postal-card recently issued to the members of the New York Academy of Medicine by the "Council of the Organization for upholding the National Code of Medical Ethics," etc., deserves a little careful examination. It contains statements that appear to me to be hardly justified by the facts. It says: "The proposed amendments, were they adopted, would eliminate from the constitution and by-laws everything relating to ethics, and surrender the Academy to those who advocate the abolition of all ethical codes.

This is a mistake, as the amendments contain a provision by means of which the council of the Academy can inquire into any alleged misconduct on the part of its Fellows. Ethical improprieties may thus at any time be made the occasion for discipline in the same manner as other offenses.

"The Academy would thereby be deprived of the right of representation in the American Medical Association, and of affiliation with other medical organizations out of the State of New York."

The first part of this is correct; but, inasmuch as the Academy is not in affiliation with "other organizations out of the State," I fail to see the pertinence of the allusion. "The code has never been made a subject of discussion in the Academy." It is perfectly correct to say that the American code has never been discussed on its merits in the Academy. Those opposed to this code have heretofore carefully avoided the introduction of any measure calculated to interfere in any way with the scientific prosperity of that body. The old-code party have also refrained from discussing the merits of that instrument, probably because they were aware that the result of such a discussion would be adverse to their views.

The postal-card states that "the resolutions presented and adopted at the last [spring] meeting of the Academy laid for their object the prevention of any future discussion relating to the code." I fail to see how the resolutions of last spring were expected to accomplish that end. Their sole effect was to influence the future membership of the Academy, so as to render it impossible for any except those in accord with the then majority to become members. No matter how eminent a man's scientific attainments, the Committee on Admissions would not be able to report favorably on his candidature. The resolutions in question could not, of course, prevent any of the existing members of the Academy from bringing up a discussion of the code. The only way to prevent that would be for the council of the Academy to copy the example of the council of the American Medical Association, and exclude from the meetings all members except those who are in favor of the Academy's present code, and who would agree not to change their minds on the subject.

The natural effect of the "resolutions" would be to excite a spirit of retaliation, and those opposed to them would have little difficulty in preventing the admission to fellowship of all who were supporters of the old code. How long the Academy would continue to flourish and prosper while such a state of affairs lasted may be readily estimated. I believe that last year the expenses of the Academy exceeded its income. If for several years to come additions to the fellowship were prevented by either or both parties, the remaining Fellows, in gradually decreasing numbers, would be obliged to pay increasing assessments in order to maintain the institution on its present footing.

The writer, and perhaps others, would regard as paying a pretty high price for the privilege of representation in the American Medical Association. The Academy is undoubtedly in an unfortunate position at the present time, and the practical question appears to be whether it is more desirable to sacrifice the American Medical Association or to sacrifice the Academy. Those who care more for the former than for the latter will oppose the passage of Dr. Barker's amendments, while those who believe that the interests of the profession of this city will be best subserved by harmony and prosperity in the Academy will support the amendments.

Academician.

NEW YORK, October 8, 1883.

NEW YORK PATHOLOGICAL SOCIETY.

A sted meeting was held September 26, 1883, Dr. G. F. Shirady, President, in the chair.

ABDOMINAL ANEURYSM.—Dr. Elliot presented the specimen, which had been removed from a man, thirty-seven years of age, first seen by him at the New York Hospital in July last. Eighteen months previously he began to suffer from pain in the lumbar region, also extending in the direction of the ureter to the testicle, and along the sciatic nerve. There was a history of alcoholism, but not of syphilis. No symptom of visceral disease could be discovered. The patient suddenly died, and, on post-mortem examination, rupture of a sacculated aneurysm of the abdominal aorta, and pressing upon the tenth, eleventh, and twelfth dorsal vertebra, was found to have taken place. The vertebrae were considerably eroded. The size of the aneurysm was about that of a hen's egg. The arterial walls immediately above and below the aneurysm, and elsewhere, and the different viscera, were healthy. Death took place about an hour after the rupture.
Dr. Van Gieson had once ventured a diagnosis of abdominal aneurysm by exclusion in a case in which no other symptoms could be obtained except those present in Dr. Elliot's case, the man being in other respects in perfect health, and the final result proved the diagnosis to be correct.

A Phthisical Lung, the Seat of Perforation.—Dr. Heizeman presented a specimen from the body of a patient who had died of acute phthisis of two months' duration. At the post-mortem examination the diaphragm was found greatly depressed by air which had entered through a perforation in the lower portion of the right lung. A valve-like action seemed to have allowed of the entrance, but not of the return, of the inspired air through the opening. The abdominal viscera immediately assumed their normal position after puncture of the diaphragm with escape of the confined air.

Splenic Infarction Followed by Abscess.—Dr. Heizeman also presented a specimen from the body of a patient twenty-one years of age, who entered Mt. Sinai Hospital last spring, suffering from occasional chilly sensations followed by irregular febrile movement. There were swelling and tenderness in the left hypochondrium. The patient progressively emaciated, and pus and a certain amount of blood were passed with the urine. The specimen of perinephritic abscess was made, and recently an exploratory incision removed about three pints of bloody pus. The patient's general condition was very low; he gradually sank, and died two days after the operation. At the post-mortem examination, infarctions of the spleen were found, and in its substance a large abscess. The kidneys were the seat of chronic nephritis, which had been one source of error in diagnosis. Vascular lesions were made out during life, and verified after death. With regard to treatment, Dr. Heizeman said we were as much justified in cutting down upon an abscess of the spleen as of the liver. He agreed with Dr. Van Gieson, who said that he would not regard pus in the urine as of much diagnostic value in perinephritic abscess. Splenic abscess seemed to be of rare occurrence; in a conversation with Dr. Delafield, the latter had stated that he had seen but three or four cases. The termination had been by perforation, with emptying of the abscess contents into the peritoneal cavity, giving rise to peritonitis.

Dr. J. Lewis Smith had once seen a case of perinephritic abscess in a child, in which for a time albumin existed in the urine. A fistulous connection took place between the abscess and the intestine. A cure was effected by operative interference and the use of a carbolic wash.

Carcinoma of the Stomach and Liver.—Dr. Ferguson presented a specimen from the body of a woman aged sixty. The symptoms of carcinomatous disease existed about eighteen months, giving rise to pain and vomiting. Just before death blood was vomited, and also passed from the rectum. She died in collapse. Extensive cancerous degeneration of the liver and of the stomach was found, and death had arisen from the opening of a large artery at the cephalic end of the stomach. The nodules were found composed largely of small round and eobdial cells. There were also a few nodules in the kidneys.

Umbilical Phlebitis.—Dr. J. Lewis Smith presented a specimen from the body of a male child eight months old. Dr. Smith saw the patient only occasionally. At birth the child appeared to be well developed, but within a few days showed febrile movement, and afterward multiple abscesses developed in the scalp and other portions of the body, apparently due to a septicaemic process. At about the second month a swelling appeared near the umbilicus, which was opened by the house physician, and bile was discharged. This opening healed, and afterward, up to the time of death, bile was discharged from the umbilicus. Inflammatiun of the left testicle at one time existed, but was recovered from. At the post-mortem examination an abscess about as large as a walnut was found in the liver, communicating with the umbilical vein, through which the discharge of bile had taken place. The vein showed signs of inflammation. The gall-bladder and ducts were normal. One of the abscesses over the occipital bone had involved the bone and the dura mater beneath. Such cases were very rare.

With regard to multiple abscess due to septic poisoning, Dr. Ferguson mentioned a case in which they seemed to have had their origin in vaccination performed three months previously, and continued eighteen months, when death took place after a fall causing dislocation and pressure of the odontoid process upon the medulla. Abscesses were also found in the brain, and contained numerous bacilli of tuberculosis.

AMERICAN ACADEMY OF MEDICINE.

The eighth annual meeting was held in the parlors of the New York Academy of Medicine, Tuesday and Wednesday, October 9 and 10, 1883, the President, Dr. Henry O. Mavoy, of Boston, in the chair.

First Day—Afternoon Session.

The meeting was opened with a prayer by Dr. Traill Green, of Easton, Pa.

The Late Dr. George M. Beard.—Dr. A. D. Rockwell, of New York, read a graceful and interesting sketch of the life of the late Dr. Beard.

The Value of an Acquaintance with Botany as a Preliminary to the Study of Medicine.—Dr. Benjamin Lee, of Philadelphia, read a paper with this title, in which he deplored the present low requirements for the admission of students to medical colleges, and the omission of accessory studies from the college curriculum, especially that of botany. He gave an account of the labors of the early professors in the Medical Department of the University of Pennsylvania in this field of teaching, and spoke of the capability of botanical study to enrich our materia medica. Reference was then made to the bibliography of botany in the United States, especially the works of Barton, Bigelow, and Carson. Some of the medicinal plants indigenous to America were described for the first time, he said, in a work by Hughes, published so early as the sixteenth century, "at the Green Dragon, outside Temple Bar," London. Of late years the development of our native vegetable materia medica had been left almost entirely to the efforts of the manufacturing pharmacists. An excellent opportunity for the study of the flora was offered the practitioner in the rural districts. Dr. Lee sought to impress upon the Academy the necessity of insisting upon the study of botany as one of the requirements for the admission of students to our medical colleges. If it were not studied before the medical course was entered upon, its pursuit would not be likely to be taken up afterward. Steps were now being taken by the Medical Society of the State of Pennsylvania to make an examination in botany a condition for admission as a medical student in that State.

The Imperfection of Technical Studies as a Means of Mental Culture.—Dr. Traill Green read a paper in which he remarked that certain eminent persons, mentioning President Elliot, Dr. Charles Francis Adams, Jr., and others, had been widely reported as holding that a classical education was unnecessary in the practical pursuits of life and in the practice of medicine. Extensive quotations were made from the writings of these gentlemen, however, going to show that their views were quite the contrary. Mr. Adams had stated in an address that a knowledge of English and Latin should always be required of a person entering on a course of professional
study, together with that of a third language, ancient or modern, at the option of the student. In his introductory address at the opening of the present course of the Medical Department of the University of the City of New York, Dr. Knapp, professor of ophthalmology, had laid stress on the importance of a broad, general, and classical education before beginning the study of medicine. The paper was an earnest appeal for higher general education in the medical profession.

Is it Fair? A Study of the Comparative Political Position of the Medical Profession of the United States.—In a paper with this title, Dr. Charles McIntire, Jr., of Easton, Pa., compared the requirements for the practice of law and of medicine in different localities, together with the influence of members of the two professions with the community and politically, showing that the influence of the two was in proportion to their general culture.

Higher Medical Education.—Dr. Albert L. Gibson, of the navy, read a paper on this topic. To show the need of a higher education in general on the part of American physicians, he gave amusing examples of the inability of some of them to spell words in common use. For instance, one gentleman, writing for information with regard to admission into the medical corps of the navy, signed his letter "respectively yours," and addressed it "to — of the Naval Medical Bord." The Army Medical Board, the State Board of Health of West Virginia, and other examining boards had met with many instances of a like nature, and, of course, also with examples of great lack of knowledge pertaining to the special calling of medicine. Of all the applicants for admission to the medical corps of the navy during the last twenty years, only thirty-two per cent. had been found acceptable. Dr. Gibson showed the necessity of the study of Latin and Greek, surgical anatomy, chemistry, botany, and other branches, a knowledge of which was not generally made a condition for granting the degree of doctor in medicine; the need of a four years course in medical colleges; of power on the part of the colleges to grant the degree of bachelor under certain restrictions to graduates of three years' standing; and of the establishment of disinterested boards of examiners for degrees. He made some interesting points founded on the data given in the Students' Number of the "New York Medical Journal," and referred to the "gag-rule" enforced by the American Medical Association at its recent meeting, giving it as his belief that the distinction between the regular and the irregular practitioner should be based upon actual qualification, rather than on zeal in denouncing the sects.

Evening Session.

The Recent Advances of Sanitary Science; the Relations of Micro-organisms to Disease.—This was the title of the annual address by the President, Dr. Henry O. Mardy, of Boston. The address was an able exposition of the germ theory of the development of disease, and of the importance of sanitation based upon our present knowledge of the part possibly played by minute organisms in health and in disease. It was illustrated with micro-photographs projected on a screen.

Second Day.

Election of Officers.—The following-named gentlemen were elected officers for the ensuing year: President, Dr. Benjamin Lee, of Philadelphia; Vice-Presidents, Dr. Albert L. Gibson, of the Navy, Dr. Nathan Allen, of Lowell, Mass., Dr. George F. Shady and Dr. Edward J. Beringham, of New York; Secretary and Treasurer, Dr. Richard J. Dengison, of Philadelphia; Assistant Secretary, Dr. Charles McIntire, Jr., of Easton, Pa.

It was voted to hold the next meeting in Baltimore.

The discussion of the papers read at the first day's session was then taken up, and was opened by Dr. L. S. Pilcher, of Brooklyn, who deprecated the importance that had been attached to the study of the dead languages in the movement to make it a prerequisite to admission to a medical college. Had such a requirement been in force in former times, he said, the profession would have been deprived of Hunter, Cooper, Paré, Velpeau, and Sydenham. The speaker then introduced a paper.

The Relations of Medical Journalism to Higher Medical Education in America was the title of Dr. Pilcher's paper, and in it he dwelt upon the influence of medical journals in elevating the standard of medical knowledge by giving expression to the scientific work of the profession.

Dr. Steiner thought Dr. Pilcher was out of order in expressing the sentiments he had expressed before a body whose avowed object was to elevate the character of the profession.

Dr. Hunt, of Boston, by invitation, joined in the discussion, and spoke of John Hunter's saying that an academic course would have made an old woman of him. Why did he say that? Simply because the college course was four years of play, chiefly with Latin and Greek, the smattering of which that was thus acquired being of no practical benefit whatever. It had been of no use to him (Dr. Hunt), and, judging from the papers he had listened to at this meeting, it had been of little use to the members of the Academy. What was wanted was original work in the special department concerned, viz., medicine.

Dr. Gibson remarked that Hunter and the other great men alluded to by Dr. Pilcher had gone through a course of training equivalent to a college course, and that was all the Academy contended for.

Dr. Hunt retorted that the Academy would not accept such an equivalent as a qualification for membership.

Dr. Pilcher closed the discussion with the remark that he thought the Academy could not afford to stifle the expression of views that might be at variance with those of some of the older members.

The Milk Supply in Large Cities.—Dr. J. Cheston Mours, of Philadelphia, read a paper in which he referred specially to the milk supply of Philadelphia, and recommended a special method of transporting milk.

The Exact Value of the Electrolytic Method was the title of a paper read by Dr. A. D. Rockwell, of New York, in which he stated that the success of the treatment in malignant growths was trifling, although the size of the tumor was almost always reduced and the pain was decidedly relieved. Material relief was generally given in intramural fibrous tumors of the uterus when inaccessible to the knife. Electrolysis might be considered a specific for erectile and small cystic tumors, and, with proper care, a scar could be avoided. Relief was sometimes given in cases of goitre. Superfluous hairs could be permanently eradicated, and many cases of urethral stricture were much benefited. More experience was needed, however, to establish the exact value of the method in the latter affection.

A report was submitted by the Committee on the Laws of Medical Practice, Dr. Dengison and Dr. Mardy.

The Importance of Cleanliness in Surgical Operations.—Dr. R. S. Sutton, of Pittsburg, Pa., having sent a paper with this title, it was read by Dr. McIntire.

[Dr. Sutton read a paper on this subject at the recent meeting of the American Gynecological Society, an abstract of which will be found in the journal for September 22d, p. 328.]

Some Thoughts on Vaccination was the title of the concluding paper, by Dr. Lewis P. Bush, of Wilmington, Del. The author advocated compulsory vaccination, at least among the pupils in the public schools.
NEW YORK SOCIETY OF GERMAN PHYSICIANS.

A stated meeting was held May 29, 1883, Dr. Emil Rosenberg in the chair.

Tracheotomy.—Dr. H. J. Boller presented a little boy on whom he had performed tracheotomy in the early part of last January for membranous gout. He still wore the tube, because he could not breathe without it. Whether this was due to the presence of exuberant granulations near the wound, or to paralysis of the vocal cords, the doctor could not decide.

Dr. A. Jacobi said that if there was any difficulty in removing the tracheotomy-tube after the lapse of a reasonable space of time, it was commonly caused by exuberant granulations situated in the upper angle of the wound. For this reason he makes it a rule to always cauterize the wound with lunar cautery, beginning from the fifth day. In some rare instances the difficulty was with other changes in the larynx, with paralysis of the vocal cords, or with cicatricial contractions. In some cases he had succeeded in removing the cannula during sleep where it had not been practicable to do so while the child was awake, which proved that the trouble was only an account of the little patient's fears.

Dr. B. Schaarau remarked that the granulations were sometimes situated so high that they could not be seen at all. He remembered a case, of which he and Dr. H. F. Galeke had had charge some years ago, where the excrescences could only be reached by a probe, the end of which had been dipped in molten nitrate of silver. Where the presence of these growths was doubtful, it should be observed whether the dyspncea arising from the removal of the tube increased or not after some time. If the first was the case, the presence of granulations could be assumed as certain. The increase of the difficulty of breathing was due to their increasing in size by venous congestion.

Dr. A. G. Gerstner mentioned a case of tracheotomy for diphtheria which he had seen together with Dr. George Degner. The tube had been removed a short time after the operation, and the wound had promptly healed. A few months afterward dyspncea again set in, this time caused by granulations, necessitating secondary tracheotomy. The case ultimately proved fatal. He said that polypoid growths occurred, not only at the upper angle of the wound, but sometimes also below it. He recalled a case where growths thus situated impaired respiration while the tube was still in situ, and had to be removed by cauterization.

Dr. A. Jacobi said that in the great majority of cases the polypi grew from the upper angle of the wound. This circumstance proved that it was not the pressure of the tube that caused them to sprout, but the diphtheritic process itself.

Dr. Gerstner called attention to the scars which occasionally were found to occupy the posterior wall of the trachea after the operation in question. This wall was apt to put forward in the form of a fold. The fold, being subject to pressure by the tube became the seat of superficial necrosis, followed by the formation of a scar.

Absence of the Uterus.—Dr. R. Tauszky presented an Irish girl, twenty-four years old, who had consulted him for amenorrhea. Upon examination, he found a scanty growth of hair upon the pubes, and above it two tumors of the size and consistence of testicles. The vagina was one inch and a half long, and did not lead to a uterus, nor could this organ be detected by the finger introduced into the rectum.

Dr. B. Schaarau, who examined the girl, also failed to find a womb. He thought that the two tumors above the pubes were hernial protrusions. What constituted the hernia could not be made out.

Abdominal Tumor.—Dr. R. Tauszky also presented a woman, thirty-seven years of age, with a tumor of the abdomen, corresponding in size to the uterus in the sixth or seventh month of pregnancy. She had been married for four years, but never had any children. The swelling began a year ago. The menstruation was normal. The probe could be introduced into the uterus to the depth of four inches. Dr. Tauszky thought that it was either a subperitoneal fibroid of the womb, or an ovarian cyst. He had refrained from making an exploratory puncture on account of the danger of peritonitis, which was known to have followed tapping of ovarian cysts in some instances.

Peritonitis from Intestinal Perforation.—Dr. A. Seibert showed a portion of the intestines of a young man, nineteen years old, who had died under the following circumstances: He had never been seriously sick before his fatal illness, and there was especially no history of typhoid fever. He had, however, been subject to constipation, often going five or six days without a movement of his bowels. His last sickness began by his being suddenly attacked by severe pain in the abdomen while at work. He then had not had a stool for five days. He was obliged to go home, where he was seen by Dr. L. Bopp, his family physician, who diagnosed periappendicitis. The next day collapse set in, and the patient died. Dr. Seibert made the autopsy. There was purulent peritonitis, but no typanites. The vermiform appendix was missing, and a large ulcer occupied the place of its orifice. The ileo-cecal valve was remarkably narrow. It showed no electrical hardness, however, and for this reason Dr. Seibert considered it to be a case of congenital stricture of the valve. It explained the constipated habit of the patient.

Dr. A. G. Gerstner drew attention to the fact that there was no dilatation of the intestinal tube above the seat of the stricture.

Congenital Malformation of the Brain.—Dr. E. C. Spitzka presented the brain of the child from which other specimens illustrating congenital malformations had been shown to the society at the previous meeting by Dr. Boldt. The left hemisphere of the cerebrum was considerably larger than the right. The central fissure on the hypertrophied side was not well developed and could hardly be recognized. The island of Reil of the same side scarcely showed any convolutions, while the latter were well developed upon the corresponding part of the other hemisphere. The left cerebellar hemisphere was also larger than its fellow. Dr. Spitzka said that in cases of asymmetry of the cerebral and cerebellar hemispheres the asymmetry, as a rule, was found to be homonymous. The course of the fibers between the normal cerebrum and cerebellum being crossed, one would expect the opposite to be the rule. Dr. Spitzka also drew attention to a remarkable heterotopy of the medullary substance at the base of the left cerebellar hemisphere. There it displaced the cortical substance and protruded in the shape of a nodulated tumor.

Athetoma of the Aorta and the Arteries of the Brain.—Dr. H. J. Boldt presented several specimens with the following history: Mrs. M. A., aged forty-four, married, very corpulent, had been suffering from occasional attacks of headache for years. On May 10, 1883, she was taken suddenly with a feeling of prostration. Two days afterward, early in the morning, she felt a burning pain in her face, with vertigo, nausea, and vomiting. She sat down on a chair. After fifteen minutes she attempted to rise, but found that she could not move. Dr. Boldt saw her at 9.10 a.m. There was left-sided hemiplegia and hemi-anesthesia, also ptosis and paralysis of the facial nerve of the same side. The pupils were equal, and responsive to light. The tongue deviated to the right. The mental faculties were uninjured. At 9.29 a.m. she vomited, and complained of chilliness. This was followed by a feeling of heat and formi-
cution in the extremities of the right side. The left half of her forehead was covered with perspiration. At 9.30 A.M. there was a voluntary discharge from the bladder. She began to have some difficulty in speaking, as well as in swallowing. Temperature in the rectum 99.4°, in the axilla 89.2. Pulse 84, full on the right side, weak and dicrotic on the left. She complained of severe headache. At 9.50 A.M. she complained of chilliness in her right hand. Answered questions by monosyllables only. At 10 A.M. vomited again, and had another chill. At 11.45 A.M. she became unconscious. Her pupils were then contracted. The urine was voided by catheter, and was found to contain albumin. At 1.30 P.M. the pupils began to dilate. She died at 4.20 P.M. At the autopsy the vessels of the brain were found to be atheromatous, especially the vertebral arteries. There was an enormous hemorrhage in the pons which extended into the fourth and into the left lateral ventricle. The heart was the seat of fatty degeneration. The aorta was atheromatous. There was also slight fatty degeneration of the pyramids of the kidneys.

Cancer of the Liver, Duodenum, Lungs, and Vertebrae.—Dr. Boldt also presented specimens of cancer of the liver, the duodenum, the lungs, and the vertebrae, with the following history: Mr. D. B., aged forty-nine. About thirty years ago he received a heavy blow with a piece of wood in the region of the lower cervical and the upper dorsal vertebrae. He fell unconscious, and remained so for several hours. He was unable to do any work for a month. Three years ago he suffered from violent pains in his right shoulder and in the region of the right side of the cervical and upper dorsal vertebrae, which prevented him from lying on this side. After lasting for six weeks, the pains subsided again. In the early part of December, 1882, he had an attack of diarrhea which was accompanied by severe pain in the abdomen. Toward the end of the same month he was attacked by lacunating pains referred to the manubrium of the sternum and to the neighboring intercostal spaces. Two weeks later he complained of pains in the lower cervical vertebrae, radiating into the subscapular, median, and ulnar nerves of the right side. During the month of April these pains extended down as far as the third lumbar vertebra. On April 15th lacunating pains appeared in the left gastrocnemius muscle, and the left foot became oedematous. There was obstinate constipation. April 20th, complained of pain in the right leg and in the posterior portion of the plantar aspect of the left foot, May 8th, paralysis of right hand, with sensibility preserved. May 12th, vomited, without nausea. Strength failing rapidly. A nodulated tumor could be felt in the right hypochondriac region. The idea of an abscess was suggested by a double murmur, which was audible over the course of the abdominal aorta. (Edema of the lungs supervened, and he died on May 15, 1883.)

At the autopsy the liver was found to be enlarged and studded with nodules of carcinoma. The upper portion of the duodenum was degenerated into carcinoma. The lungs contained disseminate masses of this growth. The bodies of the first two dorsal vertebrae, as well as that of the last cervical vertebra, were also transformed into soft carcinomatous tissue, involving the corresponding portion of the spinal meninges. The sheaths of the nerve-trunks originating in that region were thickened.

Dr. Boldt thought that the primary seat of the pseudoplasm had been in the duodenum.

Dr. Jacot thought that the history of the case pointed to the vertebrae as the starting point of the infection.

Blindness following Facial Erysipelas.—Dr. Ernst Schottky related a case of facial erysipelas followed by blindness. It was that of a man, forty years old, who had had tertiary symptoms of syphilis already. The erysipelas began in the pharynx and the nasal cavity, and thence extended over the cheeks and the forehead. The lids became so much swollen that the eyes could not be opened for several days. The eyeballs were protruded. When the eyes could be opened at last, the sight of both was found to be entirely abolished. The pupils were contracted, but subsequently dilated again. Several deep incisions were made into the orbit, but no pus came, nor did they have the least effect upon the eyesight. He had remained completely blind ever since. During his illness he had also shown a peculiar idiosyncrasy against quinine, which drug produced urticaria.

Dr. H. Knapp, who had also attended the patient, reported the result of the ophthalmoscopic examinations which he had made.

OPHTHALMOLOGY.

By CHARLES STEDMAN BULL, M. D.,
LECTURER ON OPHTHALMOLOGY AND OPHTHALMIC SURGERY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO ST. MARY’S FREE HOSPITAL FOR CHILDREN, AND TO THE NEWBURY AND CHILD’S HOSPITAL.

The Elongation and Stretching of the Nasal Nerve.—Abadie (‘Annales d’oculistique,’ May–June, 1883) has an interesting article upon this subject. He cites the case of a lady, aged thirty-five, who ten years before had lost the right eye from some glaucomatous affection. An iridectomy had been done at that period, but the result had been unfavorable. The patient began to have similar symptoms in the left eye, and when Abadie saw her the glaucomatous condition was present. He performed a sclerotomy, but, after a week had elapsed, the pain and increase of tension returned. He then did an iridectomy, but in three weeks all the symptoms returned. He then determined to stretch the nasal nerve. An incision was made perpendicularly to the course of the nerve, extending from the pulley of the superior oblique to the tendons of the orbicular muscle. As soon as the nerve was uncovered it was seized by the forceps, and stretched so vigorously that it broke. The wound was then washed with a solution of boric acid, and a simple dressing applied. The next day all pain had ceased, and in three days the tension was normal, and vision began slowly to improve. Four months later, tension remained normal, and the vision was still improving. Since then Abadie has done this operation eight times, twice in combination with sclerotomy in cases of congenital hydropthalmus, and with encouraging results. Care must be taken in making the incision in order to avoid cutting the nerve before it is laid bare. The results furnished by the stretching or laceration of the nasal nerve in glaucoma, if confirmed in the future, will furnish food for reflection upon the nature of this singular affection. An attentive study of the pathogenetic conditions in which it arises has always led Abadie to maintain that, of all the theories offered, that of irritation of the eiliary nerves, first advanced by Donders, was still the most satisfactory. Recently the uncontesteable success obtained by sclerotomy seems to favor the ideas of Wecker of the impermeability of the channels of filtration of the anterior segment of the eye. But this hypothesis of obliteration of the channels of filtration seems now to be in danger of being overthrown by the very recent researches with fluorescein, undertaken by Pfuiiger. The manner of penetration of this substance into the cornea shows that the channel of nutrition advances from before backward through the medium
REPORTS ON THE PROGRESS OF MEDICINE.

of the circum-corneal blood-vessels. The stretching or laceration of the nasal nerve seems to be well adapted to various cases, and, like the operation of iridectomy, is capable of combating very different pathological conditions. Abahle prefers laceration of the nerve to simple stretching, for the following reason: The nasal nerve is very delicate, and hence if we desire to exert a traction which is efficacious, and which will really modify the nervous conductivity, a laceration is really necessary. He seizes the nerve with a thin, smooth forceps, and draws it out; as it elongates, he seizes it with another pair of forceps, and thus he keeps on stretching it till it ruptures.

Excessive Unilateral Strabismus.—Abahle ("Archives d'ophtalmologie," May–June, 1883) describes his method of operating for the correction of excessive one-sided strabismus as follows: He makes a cut incision in the conjunctiva at the corneal margin, with the concavity toward the muscle, and sufficiently extended upward and downward to admit of arranging two conjunctival flaps, which he calls bulbary flaps, above and below the horizontal diameter of the cornea, and which serve for fixing the suture-points. As soon as this incision has been made, the lips of the conjunctival wound gap, and the flap on the side of the commissure, called commissural flap, recedes, and from this he cuts off a portion about two millimetres in thickness. In this manner the region of the sclerosing, upon which the tendinous graft is to be made, becomes uncovered, and the advancement of the muscle is only limited by the border of the cornea itself; whereas, if the conjunctiva were detached only at a certain distance from the corneal margin, the muscular graft might be interfered with by a portion of the scleral conjunctiva near the margin of the cornea. As soon as the sutures are in place, and the tendons of the muscles have been detached, the eye is ready for the advancement, and the eyeball is turned in and brought toward the muscle, to be advanced by seizing it with two pairs of forceps above and below the vertical diameter of the cornea, and turning the eye toward the commissure; it is then held in this position by an assistant until the sutures are introduced and tied in the ordinary way. After the sutures have been tied, there should be a little over-effect, to bring about a good result. The sutures should be allowed to remain for four or five days.

Sympathetic Inflammation of the Eye.—Ayres ("Arch. f. Augenheilk.," xii, 4) has an interesting paper based upon three carefully observed cases. They are a direct contribution to the question of the transmission of sympathetic inflammation, and show that the irascibility of the optic and ciliary nerves excites sympathetic irritation and plastic iritis, and that neuritis is connected with sympathetic serous iritis. The first case was one of enucleation of a stump after papophthalmitis, in which sympathetic inflammation broke out one year later, and was cured by excision of the optic nerve. The second case was sympathetic ophtalmia following an injury to the fellow-eye, which was cured by the prolonged and continuous employment of warm poultices and other means. The third case was sympathetic inflammation following a rupture of the sclera, which was also cured by the prolonged and continuous application of warm poultices. In this case, as soon as the media cleared up, an optic neuritis was plainly visible, and, as soon as this inflammation yielded to treatment, the vision improved, and was ultimately restored nearly to the normal standard. Plastic iritis and neuritis were in this case certainly connected together.

The Elongation of the External Nasal Nerve.—Badal ("Annales d'oculistique," May–June, 1883) recurs to the subject of the treatment of ciliary neuralgia by elongation of the external nasal nerve, on which he had previously written. He thinks that the clinical facts hitherto observed are in favor of this method of treatment. The operation has succeeded in several cases in which both sclerotomy and iridectomy have failed. His manner of performing the operation is as follows: After dividing the skin and muscular layer with a bistoury, he dissects away with two strabismus hooks the subjacent cellular tissue, and then, scraping along the periosteum from below upward with one of the hooks, he pulls out the vascular-nervous bundle. The vessels are then separated from the nerve, in order to avoid any unnecessary hemorrhage, and the nerve is then stretched as far as may be necessary.

The Vortex and the Nuclear Arch of the Human Lens.—Becker ("Arch. of Ophthalmology," xii, 2) has a very careful and interesting paper based upon the examinations of a one-cell entirely meridional section of a lens, with the adjoining layers, taken from the eye of a prematurely born infant, which died during birth. The lens was imbedded in an albumin-glycerine mass, and sections cut with Thomas's large microtome, which were hardly more than 0.01 mm. in thickness, through the entire lens. These sections furnished very accurate measurements of the dimensions of the lens. The transition from the anterior to the posterior surface being very abrupt, the form of the entire lens, in spite of the different curvature of the two surfaces, is more spherical than that of the adult. The capsule varies much in thickness, the average at the anterior pole being 0.008 mm., and at the periphery 0.01 mm. In the equatorial region, shortly before the epithelial cells are placed obliquely toward the capsules, the thickness of the capsule is diminished to 0.0059 mm., and opposite the vortex to 0.0047 mm. Farther back, at a point still within the insertion of the zonule, the capsule increases rapidly in thickness up to 0.024 mm. The dimensions of the epithelial cells and their insertion at the inner surface of the capsule change with the locality. In the region of the anterior pole they are short hexagonal columns, with a diameter of 0.01 mm. at the base. The almost spherical nucleus lies in the center of the cell. Toward the equator, where the capsule becomes thinner, the cells slightly increase in diameter, and the nucleus occupies the end toward the interior of the lens. The increase in length of the fibers at the vortex of the lens affects especially that part of the cells which lies nearest the capsule. The nuclei of the cells at the vortex do not differ in size from the nuclei of the anterior epithelium, but they are more elliptical in shape, and are placed vertically to the axis of the lens. Therefore, seen from the surface, the nuclei must appear smaller and nearer together, since the cells become at the same time smaller. As soon as the cells of the vortex begin to be elongated at their anterior end, the elongation takes place much more rapidly than the increase at the posterior end, so that the nucleus soon comes to lie in the center of the fiber. This more rapid increase at the anterior end continues for some time, until gradually the posterior end increases more, and the nuclei then take their place at about the anterior third of the fiber. This arrangement causes the nuclei of the nuclear zone to form at first an arch with the convexity backward, which later passes over into an arch with its convexity forward. For this double arch, in which the nuclei are arranged in a curved line which has been called nuclear zone, Becker proposes the name of nuclear arch. The nuclei at the vortex become more and more elliptical, and at the same time increase in size. At first they show a bright and uniform staining, but farther back the contents of the nuclei become separated into isolated granules, separated by a transparent substance. The vortex and nuclear arch of the human lens vary considerably according to age. The number of cells, which are elongated at the base only, decreases with age. The portion of the nuclear arch which is convex posteriorly contains fewer nuclei. In the same manner the number of those fibers which do not reach the radii of the star figure decreases with age, but they do not disappear entirely.
A CASE OF ECTOPIA OF THE EYEBALL CAUSED BY OSTEOPHITIS OF THE ORBITAL ROOF, WITH CONSECUTIVE PERNATORY OF THE SUPERIOR ORBITAL REGION.—Birnbacher (“Arch. f. Augenheilk.,” xii, 4) reports a case of this nature in a young man, aged seventeen, who had suffered from hydrocephalus in infancy. When the patient was first seen, on April 12, 1881, the right eye protruded, but there was no limitation of motion, vision was normal, and the fundus was healthy. In the following September the upper orbital margin was found thickened. On February 10, 1882, while the patient was blowing his nose, there suddenly appeared a tumor under the right eyebrow, which during the night disappeared. This appearance can still be produced by an act of the same nature, and shows a smooth surface, distinct limitations, and is elastic. The percussion note over the tumor was tympanitic. On March 14th an exploratory incision with a Pravaz needle and syringe met with considerable resistance, and gave exit only to air, and the tumor immediately became very much smaller. On April 2d an incision was made parallel to and just below the margin of the eyeball through skin and subcutaneous cellular tissue, from the external orbital angle nearly to the upper border of the lacrimal sac. The periosteum was then divided for the same length, and dissected up from the bone for a distance of 3 mm. in breadth. This opened into a cavity, which, besides air, contained two large partitions and one small portion of a reddish-gray, spongy bone, which jutted downward toward the eyeball. They arose from a fine, spongy mass of bone which formed the roof of the orbit. They extended 2 cm. deep into the orbit, and represented combs or ridges, over which the periosteum of the orbital roof was stretched, being in contact with bone only along their lower free margins. These combs or ridges thus projected into the cavity like stalactites. These three combs were removed with the chisel. Behind them the periosteum was found covered with small, hard, bony plates with sharp ridges, and these were also removed by the chisel, as were also numerous spongy, bony excrescences from the roof of the orbit. No actual incised frontal sinuses could be found, nor could a probe be passed through the spongy bone of the orbit into the nasal cavities. After the cavity had been washed out, the eyeball could be replaced in the orbit. The incision in the periosteum was then united by carbolized catgut sutures, and a drainage-tube placed at its inner angle. The external wound was then closed by silk interstices as far as the drainage-tube, and the whole dressed with Lister's dressing. The patient made a good recovery.

INVESTIGATIONS INTO THE RAPIDITY OF RETINAL REACTIONS.—Charpentier (“Arch. de physiologie,” May 15, 1883), in a lengthy article, proposes to elucidate the following points: 1. To determine the retardation of visual reactions in direct vision and in several eccentric directions of the visual field. 2. To exercise during a certain number of experiments the direct vision and a fixed eccentric point of the visual field. 3. To determine the influence of this exercise upon the duration of the reaction of the two points in question. 4. To determine in what degree the exercise of a definite point of the retina may influence other retinal points more or less distant, as well as the other unexercised eye. His experiments have led him to conclude that irritation of the eccentric parts of the retina in the normal state does not admit of as rapid reactions as in direct vision, but that exercise diminishes in great measure this inferiority. It is not difficult to believe that a very prolonged exercise would render all the regions of the retina almost equally perceptible, and that obstacles might eventually be avoided with the same rapidity by all parts of the visual field. We know that the influence of this habit or exercise is exerted in great part through the medium of an encephalic center, which unites the median part of one retina with the lateral part of the other, and which seems to be modified in its entirety by the irritation of a limited point of one of the hemispheres of the retina which communicate with it.

A CASE OF PULSATING EXOPHTHALMUS; LIGATION OF THE LEFT COMMON CAROTID; DEATH.—Coggin (“Arch. of Ophthalmology,” xii, 2) reports a case of this nature in a woman aged sixty-six. She first complained of noise in the left ear in February, 1882, which was supposed to be due to chronic catarrh of both middle ears, for which she was treated, but with no result. About the middle of April she complained of loss of sight in the left eye. There were slight convergence and some protrusion of the eye, incipient cataract, but no change in the fundus. On May 8th pulsation of eyeball was visible and recognized by palpation. The external rectus was paralyzed. Through the stethoscope, placed over the eye, a loud bruit was heard, which ceased on pressing the left common carotid, as did also the noise in the head. Some relief was gained by a pressure bandage over the eye, and tincture of veratrum viride in doses gradually increased to five minimis every hour. Digital pressure on the carotid was not tolerated longer than seven minutes. On June 1st the left common carotid was ligated in the upper part; no bruit could afterward be detected with the stethoscope, and the eyeball receded somewhat. The patient died, hemiplegic on the right side, on the fifth day. At the autopsy the temporal parietal and occipital lobes of the left hemisphere of the brain were found softened and friable. The venous sinuses were normal. The ophthalamic vein was larger than usual. There was no aneurysm of the ophthalamic artery. On exposing the carotid artery in the course through the temporal and sphenoid bones, a marked aneurysmal dilatation of the cavernous portion was revealed, due to fatty degeneration.

THE PROPHYLAXIS OF PULMONARY CONJUNCTIVITIS IN NEW-BORN INFANTS.—Credé (“Archiv für Gynakologie,” xxi, 2) publishes a third article on this very important subject, the first two having appeared in Volumes XVII and XVIII of the same journal. The means he employs are absolutely simple and entirely devoid of danger, and the results unexpectedly favorable. He gives a brief summary of the observations made during the last thirteen years in the Leipsic Lying-in Hospital. During these thirteen years there were 4,657 living children born in the hospital, and of these 318 suffered from paroxysmal conjunctivitis, or 7.8 per cent. He began his prophylactic treatment on June 1, 1880, and in the seventh months of 1889 there was one case in 211 births, or 0.49 per cent., but this case should not be reckoned, as the child’s eyes, from an oversight, were not disinfected. In 1881 there was one case in 400 births, or 0.25 per cent; but in this case the conjunctivitis began on the ninth day, probably by infection with the lobal discharge. In 1882 there were two cases in 418 births, or 0.49 per cent. In the first three months of 1883 there were 131 births and no case of ophthalmia. Most obstetricians and ophthalmologists at present believe that the ophthalmia of new-born infants is almost exclusively caused by contact with the secretion of the vaginal mucous membrane during parturition. This view, of course, prevails only in regard to those cases which begin within the first five days after birth. Credé holds that the normal secretion of the vaginal mucous membrane can only produce a simple catarrhal inflammation of the conjunctiva, and that a specific gonorrhoea of the conjunctiva can never be produced in an infant without there being a specific gonorrhoea of the vaginal passage. If, then, we assume that the contact of the child’s eyes with a genital secretion which contains specific poisonous germs produces the blenorrhoea, then the danger of this infection is the greater the longer the contact lasts. It is not always possible to demonstrate a gonorrhoea in the vagina of all parturient women examined. The duration of the stage of incubation is still in an unsettled state, the data being as yet insufficient to formulate any decided
state. Credé now employs the prophylactic treatment in all children, without exception, immediately after birth. Vagi-
nal injections are employed daily in all women approaching their confinement. As soon as the umbilical cord has been tied and cut, and the child has been bathed, the eyes are washed with ordinary water, and then the lids are slightly opened and a single drop of a two-per-cent. solution of silver nitrate dropped, by means of a glass rod or tube, into the eye; it may be directly on the cornea. No unpleasant consequences have ever been seen to follow, though slight conjunctival hyperemia and swelling and a slight secretion have often been seen; but these symptoms all disappear without any treatment in from one to two days. In most children there is no reaction. By this method of treat-
ment he has reduced the percentage of cases of ophthalmia neonatorum from 10 to 0.2.

Granular Ophthalma and Jequirity.—Deneffe ("Recueil d'ophthalmologie," May, 1883) gives the result of his experience with the use of jequirity in the treatment of granular conjuncti-
vitis with or without pannus. He has tried the two solutions recommended by Wecker, and has not found that one is superior to the other. He does not think that the patients should be kept in a darkened room, as advised by Wecker, for he has seen the inflammation caused by the jequirity infusion develop just as violently in the light as in a darkened room; and, when it was not developed in the eyes of a patient when exposed to the light, the confinement of the same patient to a darkened room did not exert any influence in developing it. The pain which accompanies the inflammation is sometimes very violent, and he has occasionally seen patches of erysipelas-like inflammation invade the face and neck. From a therapeutical point of view, the jequirity infusion gave no results. After a violent in-
flammation, which was renewed after several weeks, there was no amelioration in the granulations. None of the cases treated in the prescribed way by jequirity at the Ghent clinic showed any amelioration whatever. The drug proved absolutely useless in the treatment of pannus, while in one case it changed a vascu-
lar keratitis into a pannus crassus, which subsequently had to be treated by purulent inoculation; and in another it probably produced perforation of the cornea. Deneffe thinks that the granulations spoken of by Moura Brazil, as produced by pur-
ulent conjunctivitis, are papillary granulations; the hypertrophy of the papillae succeeds the conjunctivitis, and the formation of transitory inflammation produced by jequirity easily causes this hypertrophy. True trachoma, or engorgement of the lymphoid cells, is not the result of inflammation of the conjunctiva, and has nothing in common with hypertrophy of the papillae. True trachoma is not influenced by jequirity inflammation.

Contribution to the Literature of the Semi-Deaussion of the Optic-nerve Fibers in the Optic Chiasm of Man.—Deutschmann ("Archiv für Ophthalmologie," xxix, i) gives the results of his examination of the eyes of a deceased inmate of the local lunatic asylum, one of whose eyes had been lost forty years before, and the other one was intact. He found atrophy of the optic nerve on the injured side and atrophy of both optic tracts. The degeneration of the optic nerve close to the chiasm was not complete, and it was partial in both tracts, being more pronounced in the tract on the opposite side. The most marked atrophy was in the optic nerve on the injured side in the inner, upper, and supero-temporal segments, and less marked in the lower and infero-temporal segments. The most marked degeneration was on the inner side of the left optic tract.

Cerebral Abscess with Bilateral Choked Disc: Basilar Menin gitus and Perineuritis and Descending Interstitial Optic Neuritis.—Deutschmann ("Arch. für Ophthalmologie," xxxi, i) reports a case of this nature occurring in a boy aged nine and a half years. He regards the perineuritis and optic neuritis as the direct result of the meningitis which accompa-
nied the cerebral abscess. The exudation which distended the intravascular space arose from the perineuritis, and was of inflamma-
tory origin, as there was no drop of the ventricles present. The fact that the inflammatory process was most marked at the ocular end of the optic nerve does not militate against the de-
sending nature of the lesion.

The Treatment of Detachment of the Retina by Iridec-
tomy.—Dransart ("Annales d'oculistique," May–June, 1880) ad-
vises a return to the method of iridectomy in certain cases of
detachment of the retina. He admits that pilocarpine cures cer-
tain cases, but the cure of detached retina is one of the great-
est desiderata of medical science. The treatment by galva-
opuncture has not fulfilled the brilliant hopes to which it at first gave rise. In a patient with anterior synechia, seen some years ago, with loss of vision and severe neuralgic pain on the same side, the ophthalmoscope showed an enormous detachment of the retinal. He made a large iridectomy upward, with the re-
sult of causing a cessation of the pain and a restoration of the vision. A second ophthalmoscopic examination showed that the retina had become reattached throughout. He has since then performed an iridectomy in cases of detached retina where the patients would consent to it. Three were cases of old de-
tachment, in which the result was relatively successful. In two cases of recent detachment the success was complete, vision being restored in all its integrity. After the operation the pa-
tient is kept in bed, with a compressive bandage, and with the very moderate use of pilocarpine (four to five injections for each patient).

Unicocular Reflex Iridoplegia, Associated with Nerosis of the Orbital Roof on the Same Side, and with Double Optic Neuritis.—Eales ("Ophthalmic Review," August, 1883) reports a case of this nature in a man aged twenty-eight. On ad-
imission to the hospital, September 4, 1882, he complained of continuous headache, with frequent delirium and double optic neuritis. There was a fluctuating swelling above and on the outer side of the right eye. Three years previously he had con-
tracted syphilis. In October, 1881, he received a blow over the right temple, and had suffered ever since with almost continu-
ous headache, but had had no vomiting. Laterly a swelling had formed over the right eye. When Eales saw the patient on September 6, 1882, he was suffering from continuous mattering delirium, and was only roused with great difficulty to reply to questions, his answers being for the most part incoherent. He complained of severe pain in the head. There were great swelling, redness, and heat of the upper lid on the right side, most marked just below the external angle of the orbit, between it and the eyeball, presenting distinct fluctuation. The eyeball was not much displaced or protruded, but movement upward was limited. There was well-marked double papillitis of equal intensity in the two eyes. A free incision was made into the swelling under the carbolie spray, and an ounce and a half of hot pus was evacuated. On introducing the finger into the wound, an area of necrosed bone, as large as a shilling, was felt just within the external angle of the frontal bone, in the roof of the orbit, and apparently not extending very far back. The wound was dressed antiseptically, a drainage-tube being inserted. The patient was taking large doses of potassium iodide and mercuric bichloride, and under this treatment he grew better and was discharged. On May 12, 1883, Eales saw him again, and found the following condition: He was sluggish in comprehending questions, his speech was thick, and his bear-
ing defective in the left ear. From a sinus over the external angle of the right orbit a piece of necrosed bone projected, but there was scarcely any discharge from the sinus. The external angle of the frontal bone and adjoining superciliary ridge ap-
REPORTS ON THE PROGRESS OF MEDICINE.

peared to be absent. There was no trace of the previous papillitis, except a few whitish streaks in the immediate vicinity of the disc and vessels. $V = \frac{14}{11}$. The field of vision was normal for colors. There was slight limitation of motion upward in the right eye. Accommodation was good with either eye up to five inches, but convergence was not maintained, the left eye deviating outward. The right pupil was fixed in a state midway between dilatation and contraction, and did not respond to light, but contracted readily during convergence. On June 14, 1883, he was seized suddenly with loss of power on the right side, accompanied by stiffness and inability to speak, which lasted an hour or so, but he did not lose consciousness. When his speech returned, he could not be understood for several hours. His muscular power was considerably less in the right hand than in the left. These conditions have since remained unaltered.

The most interesting point in the case to Eales was the iridoplegia; first, because of its being uniocular; second, because of its occurrence in a syphilitic male; and third, because of its association with optic neuritis and cerebral disease, and not with primary optic atrophy and spinal disease, as we usually find it in locomotor ataxy and general paralysis.

**Left Hemilateral Atrophy of the Face.**—Eperon ("Archives d'ophtalmologie," May-June, 1883) reports a case of facial trophic-neurosis in a man aged forty-one. The left orbital cavity was much more pronounced at its upper part than in the normal state, and the left eye much more sunken. The left cheek was without any whiskers, and markedly diminished in volume. The nose, mouth, tongue, and uvula were turned to the left side. The two lips were divided into two unequal parts by an apparently cicatricial furrow. The chin was furrowed and thrown toward the left. The left ear was slightly atrophied, and the hearing on this side slightly impaired. The patient had been healthy up to nine years of age, when he had an attack of measles. Six months later a tumor appeared under the angle of the jaw on the left side, which disappeared at the end of six weeks, and from this period dated the left unilateral atrophy of the face. In the left eye there was a hypermetropia of three dioptres (+D 3), a very pale optic disc, circumscribed spots in the region of the macula, and atrophy of the choroidal pigment. In the right eye there was a hypermetropia of D 0.5, and a normal fundus. Eperon thinks that the history of this case is a striking confirmation of the theory that hypermetropia is the result of an arrest of development of the eyeball. The arrest of development of the left side of the face, with its cavities and organs, was most pronounced. The right side presented a normal development and an almost emmetropic eye; the left side showed a considerable diminution of all the dimensions and a hypermetropic eye.

**Sarcoma of the Internal Region of the Left Eyelid; Extirpation; Autoplastic.**—Eperon ("Archives d’ophtalmologie," May-June, 1883) reports a case of this nature occurring in a woman aged thirty-two. The tumor occupied the internal angle of the left eye, the bridge of the nose, and a part of the cheek, and had grown rapidly in the space of six months, so as to completely obscure the interpalpebral aperture. The tumor measured 32 mm. in height, was firm, slightly elastic, and easily movable under the skin. It was removed entire by an incision made about a centimetre around its margin, and extending down to the bone all round. The incision began on a level with the inner canthus, about 3 mm. below the palpebral border, the latter being left intact. It then extended vertically downward, ran round the lower part of the tumor, ascended along the side and bridge of the nose, and ended just below the inner end of the eyebrow. To fill in the somewhat irregularly shaped cavity left by the removal of this mass of tissue, Landolt dissected out a flap of thecezoid form in the in-
compression of the left carotid was maintained by the patient
with a compressor made of a wooden knitting-needle, with its
head protected by a firm pad. Compression was kept up by
the patient for two minutes at a time every quarter of an hour.
Compression was begun on September 30th, and was kept up,
with but slight interruptions, until December 21st. The large
vessel at the inferior inner angle had ceased to pulsate, the
sclerotic injection had passed away, a few large and tortuous
conjunctival veins ramifying over its surface standing out in
bold relief. There was no pulsation to be felt at any part of
the orbit, the patient was free from pain, and no bruit could be
detected. There was an old blood-clot at the bottom of the
anterior chamber, and the tension of the eyeball had increased
to T+3, and with no perception of light.

Hemeralopia and Xerophthalmia from Disturbances of
Nutrition.—Gouvea ("Archiv für Ophthalmologie," xxix, 1) has
found that in all the cases of xerophthalmia due to disturbances
of nutrition which he has observed, hemeralopia always preceded,
by a shorter or longer period, every xerotic change in the con-
junctiva; it accompanied this disease, and in the advanced stages
of xerophthalmia it became a real amblyopia. In all cases this
hemeralopia was accompanied by a more or less marked condition
of anemia, which was caused sometimes by an insufficient nutri-
tion or by an exclusively vegetable diet; sometimes by the presen-
tce of anchylostoma duodenale in the intestinal canal; some-
times by hemorrhages; sometimes by long-continued febrile dis-
orders; but in all the cases the patients had been more or less
exposed to the action of the sun's rays or of some other bright light.
He found that the hemeralopia sometimes appeared epidemically
in a large number of persons. The blinding by bright light he re-
gards as the exciting cause of the hemeralopia. In the beginning
of the hemeralopia the conjunctiva is almost bloodless, but after-
ward shows no trace of any blood-vessels. Near the corneal
margin it becomes of a dark color, and loses its brilliancy and
lubricity. The next symptom is the development of a froth like
substance which is attached to the more exposed portions of the
ocular conjunctiva, and to the conjunctival margin of the cornea
if there is any raw surface here. The mucous membrane becomes
dryer, and finally assumes the skin-like appearance which von
Graefe described as an acute xerosis. In this state the sensibility
of the cornea is almost lost; and at this period there is observed
for the first time a subconjunctival and circum-corneal venous
injection, accompanied by photophobia and lachrymation, and
followed by a diffuse opacity of the cornea, which, beginning at
the margin, spreads over the entire cornea. Afterward, pale-red,
flattened follicles are developed in the conjunctival fornix; the
frothy substance increases so that it forms actual scales on both
sides of the cornea, and even upon it. The xerosis extends over
the entire ocular conjunctiva, the subconjunctival veins become
more injected, and the sclera assumes a dark-blue color. In
view of all these symptoms, Gouvea proposes for this disease the
name of xerophthalmia cachectica. The treatment must be par-
ticularly directed toward improving the depressed general con-
dition of the patient. Locally, Gouvea recommends steam baths
of 40° centigrade for the cornea, several times a day, and the
eyes are to be kept bandaged in the intervals.

The Action of Continuous Electric Currents Applied in
the Neighborhood of the Brain, and the Results which
They Produce, especially on the Eye.—Grandmont ("Recueil
don'ophthalmologie," July, 1883) has been making some experi-
ments upon the action of the galvanic current upon the brain
and eye, and his method of procedure is as follows: The elec-
trons of his battery consist of discs of coke, covered with chamois-skin.
The negative pole is placed above the orbit over the course of the supra-orbital nerve or near it. The positive
pole is placed on the neck behind the angle of the jaw, nearly
in the direction of the superior cervical ganglion. He avoids
producing phosphines by keeping the electrodes immovable.
The current is allowed to pass for four or five minutes, not
longer. Grandmont found it very difficult to determine wheth-
er, during the passage of the current, there was any augmenta-
tion or contraction of the vessels of the fundus. He also found
it fully as difficult to determine whether any contraction of the
pupil took place. To facilitate these observations, he devised
what he calls an ocular thermometer, which measures mathe-
umatically the modifications obtained in experimentation on
the eye. It consists of a shallow plate or basin, so curved as to
fit accurately into the lower conjunctival cul-de-sac without
causing the patient any pain. The stem or pedicle is divided
into tenths of a degree. By this instrument he has discovered
that, after the application of the continuous current, the ocular
temperature has been lowered from two to six tenths of a
degree. At the moment of the passage of or of the interruption
of the current, phosphences are also seen, and these subjective
sensations are the more luminous the less the retina is altered.
In cases of long-continued amaurosis, even a very pale sensation
of light can scarcely be expected.

The Representation of the Limits of the Visual Field.
—Hilbert ("Arch. f. Augenheilk.," xii, 4) has been investigat-
ing the various means at our disposal for representing the
limits of the field of vision, and comes to the following conclu-
sions: 1. The visual field marked out upon the blackboard is
the most useful for the practical man. 2. An entirely correct
idea of the configuration of the visual field can only be obtained
when a Scherk's perimeter is employed. 3. The visual fields
registered by the perimeter-schemes or tables are distortions.
4. The angles belonging to the visual fields presented by the
blackboard may easily be reckoned or calculated. 5. A visual
field marked out by angular measurements may easily be con-
structed as a surface-projection. 6. The position of the macula
lutea belongs in the center of the visual field.

Foreign Bodies Encapsulated in the Background of the
Eye, with Maintenance of Good Vision.—Knapp ("Archiv
für Augenheilkunde," xii, 3) reviews the twelve cases of this
kind hitherto reported, and adds one of his own, in which the
cornea, iris, lens, and vitreous were perforated by a fragment
of iron, which became partially encapsulated in the retina, with
one end lying free in the vitreous. There was a circumscribed
scotoma, with vision of §3. In all the cases but one the size of
the foreign body was not above 2 mm. in diameter. In all but
two of the cases the foreign body was either iron or steel.
In all, the inflammatory reaction was but slight. The lesions in
the fundus were circumscribed lacerations of the retina and choroid,
and hemorrhages resulted in circumscribed thickening of the
retina and circumscribed pigmentation and atrophy of the
choroid. The functional disturbances consisted first in darken-
ing of the visual field, later in a permanent scotoma which was
larger than the site of the foreign body. The central visual
acuity was more or less well preserved in all the cases.

A Case of Traumatic Pulsating Exophthalmics Partial-
ly Cured by Ligature of the Common Carotid; totally
Cured by Extirpation of the Aneurysmal Varix of the
Orbit.—Knapp ("Arch. of Ophthalmology," xii, 2) reports a
case of this kind in a woman aged forty-eight. As the result of
a blow on the left temple seven years before, she had com-
plete left-sided facial paralysis, which had never disappeared.
Soon after the injury the eyelids were swollen, and the eye
protruded so that the lids could not be closed, but the sight
was good. In the course of some months she heard a throbbing,whirring noise in her head. Four years after, the latter the
vision of the left eye began to fail. When Knapp first saw her
the protrusion of the eye was forward and downward, and the

---

422 REPORTS ON THE PROGRESS OF MEDICINE.

[ N. Y. Med. Jour.,

---
lids could not be closed over it. Motility was limited in all directions. Lens opaque, but perception and projection of light good. Lids blue-red, and greatly swollen. Lids, temple, forehead, nose, and upper parts of cheek pervaded by a dense network of tortuous and dilated blood-vessels, varying in size from that of a thin straw to that of a large quill, and all pulsating visibly. The skin was swollen and red, and the facial paralysis still marked. With the stethoscope, aneurysmal whirring was heard wherever the blood-vessels were distended. The same bruit was audible and well-pronounced in the mastoid and temporal regions. A diagnosis of traumatic pulsating exophthalmus, due to arteriovenous communication in the left cavernous sinus, after a rupture of the internal carotid, was made. Dr. H. B. Sands tied the left common carotid artery on November 29, 1880, a calibrated catgut ligature being applied to the artery just above the omohyoid muscle. Immediately after the operation a faint systolic murmur was heard over the eyeball, and forty-eight hours later feeble pulsation was detected in the vessels above the orbit. In the course of a year the swollen vessels of the face gradually diminished in size and disappeared. During the summer of 1882 the orbital part of the disease took a new start, and the eyeball protruded so much that the lids could not be closed over it. An ulcer developed on the lower part of the cornea, and led to total slough of the cornea. The upper lid was distended by irregular, red, veniform intumescences. Pulsation was felt in all parts of the tumor, and a distinct aneurysmal bruit was heard over the whole tumor. Knapp first exploded the eyeball, and then found the whole orbit and adjacent region filled with an irregular, pulsating mass, and he then determined to remove the tumor as a whole after enlarging the palpebral fissure toward the temple by an incision; the large blood-vessels in the upper part of the tumor were carefully dissected from the overlying skin. At the orbital margin the vascular mass was found to press directly against the bony walls, but was separated from the periorbitum by a thin layer of connective tissue. Dissection here was carried on carefully with strabismus scissors and the finger. Deeper in the orbit the connection between the tumor and orbital wall was looser. Penetrating in this way from the outer-upper corner of the orbit toward the apex, it was found that near the apex the tumor contracted into a single resistant, pulsating vessel, about as thick as the little finger. When the whole tumor was separated from its surroundings, a ligature was placed round the pedicle as near the apex of the orbit as possible, and the pedicle was then divided. The patient made a slow but good recovery, and eight months later there was no return of the noise in the head or of the pulsation.

(To be concluded.)

Therapeutical Notes.—Acetate of Morphine Hypodermically for Seizures.—Mr. Philip Vinson, Surgeon to the Concord Royal Mail Service ("British Medical Journal," August 18, 1888) reports a case in which three-minim doses of liquor gelatini fluid, U. S. P., given every four hours, caused, within twenty-four hours, diplopia and dizziness of sight, and also paresis—complete of the left eyelid, partial of the right. The drug had been given, together with a quinine mixture, for severe neuralgia of the face. The neuralgia was speedily cured, and the diplopa and ptosis were relieved within twenty-four hours by a simple quinine mixture.

The Direct Action of Ethyl (Common) Alcohol upon the Heart.—Dr. H. Newell Martin, of Baltimore, Professor of Biology in the Johns Hopkins University, in a paper read before the Medical and Chirurgical Faculty of Maryland ("Maryland Medical Journal," September 6, 1883), detailed the results of his experimental investigations on the direct action of ethyl alcohol upon the heart. Professor Martin found that half a fluidounce of absolute alcohol, diluted with nearly two ounces of water, given in one dose to a human subject who had been a total abstainer, caused no quickening of the pulse. The dose was, however, sufficiently large to cause dizziness. On the other hand, a little sweetened water occasional in the same subject (who supposed he was taking alcohol) an almost immediate increase of four beats in the pulse rate. This increase the experimenter attributed, however, more to the muscular exertion made in taking the liquid than to any other except psychical causes. Numerous other experiments were made upon dogs, to determine the direct and immediate action of alcohol upon the heart, both as to the rate of pulsation and as to the amount of work done in any given time. In order to eliminate the indirect action of the alcohol—the effect that would be reflected from the central nervous system—the heart and lungs of the animal were isolated from the rest of the body. Uniform respiration was kept up artificially. The heart was fed by defibrinated blood previously obtained from other dogs, constant pressure being secured by Marliotte bottles. Certain of these bottles held oxygenating blood containing a definite known percentage of alcohol. The blood in other bottles was free from alcohol. Certain stop-cocks made it possible to connect any of the bottles at will. The apparatus recorded the pulse rate and the arterial pressure automatically. Furthermore, the amount of blood pumped during any given period of time could be easily calculated. The two sorts of blood, one free from and the other containing alcohol, were alternately supplied for the supply of the heart. To avoid ascribing the alcohol any results that might be due to independent enforcement of the heart, all experiments in which the heart did not recover from the action of the alcohol were rejected.

It was found that alcohol, in proportions not directly poisonous, did not affect the rate of pulsation. Blood containing one eighth per cent. of volume of absolute alcohol did not affect the amount of work done. Blood containing one fourth per cent. of volume of absolute alcohol almost invariably diminished markedly the work done. Blood containing one half per cent. always diminished it, and might so reduce the amount pumped by the left ventricle that it was not sufficient to supply the coronary arteries. (One fourth per cent. of the blood of a man of 150 pounds weight would be about 0.46 of an ounce. This amount of alcohol is less than that contained in many a single drink of whiskey or brandy.)

The alcohol, in Professor Martin’s opinion, did not act on the heart as it flowed through its cavities, but only when it reached the muscular and nervous tissues of the organ supplied by the coronary arteries and their ramifications. It was found that, if the pericardial sac was cut away, blood containing one half per cent. of alcohol had little or no effect on the work done, even by the same heart that had been markedly influenced by blood containing the same percentage of alcohol before the pericardium was removed. It was found, furthermore, that, under the influence of alcoholic blood, the ventricles did not contract completely. Even at the height of the systole, the heart nearly or quite filled the pericardial sac. There was, therefore, little room for further expansion during diastole, unless the surrounding sac was cut away. These facts led to the conclusion that the direct action of the alcohol upon the muscular fibers of the heart was more at first to diminish their tone and elasticity than their contractile power. The diminution of work was manifestly due to the disadvantage under which a flabby muscle must act when it has not room for its full play in contraction and relaxation. However, blood containing one fourth to one half per cent. of alcohol will in time decrease the work done, and finally reduce it to zero, even with the pericardium removed. One per cent. of alcohol will produce the same result more speedily. Exactly how the alcohol acts on the ultimate muscular fibers of the heart, Pro-
Professor Martin does not attempt to say. As alcoholic blood holds its oxygen more firmly, and, therefore, yields it less readily to the tissues, and as the heart in the previous experiments assumed an asphyliated appearance, it is probable that at least part of the deleterious action of the alcohol is due to the deprivation of oxygen it causes.

Further experiments showed that, if given by the stomach, a much larger percentage of alcohol was required to influence the blood pressure perceptibly. Either the absorption was so slow that the heart-poisoning limit was not at any moment reached, or, more probably, the alcohol was detained by the liver or other organs, and held back from the heart. One fourth cent. introduced, in a saline solution, into the jugular vein caused a temporary lowering of blood pressure; but the effect scarcely lasted longer than the brief period during which it was immediately coursing through the vessels of the heart itself. The blood coagulated with its alcohol before it was returned to the heart, to such an extent, at least, that not enough was left to produce distinct results.

Professor Martin made no attempt to study the chronic action of alcohol, deeming that a pathological rather than a physiological question.

Cold Alcohol as an Anaesthetic; its Value in the Treatment of Burns and Scalds of the Extremities.—Dr. Roger Keys, of Philadelphia ("Medical Bulletin," September, 1883), has found that alcohol at between 47° and 55° F. possesses decided anaesthetic properties. The pain of burns and scalds of the extremities is speedily and entirely removed by immersing the parts in alcohol of this temperature. If this treatment be pursued in time, the formation of blisters can be prevented. The temperature of the alcohol is to be kept within the "anaesthetic range" by means of ice and a thermometer. The immersion is to be continued until the pain is bearable on its discontinuance. The alcohol retains its anaesthetic properties even when diluted to twenty-five per cent. Dr. Keys discovered these facts some years ago when trying to relieve the pain he was suffering from burns on his own hands. He had for years successfully treated burns and scalds of the extremities with cold alcohol. He advocates the same treatment in the case of more extensive burns of the body and trunk, believing it affords the best means of averting death. [If "cold alcohol" really has anaesthetic properties, what limits its use in fevers, contusions, and injuries of the hands and feet, and, indeed, in all painful affections of the extremities?]

EFFECT OF METALLIC POISONS ON THE SPINAL CORD.—The affections of the nervous system produced by contamination with certain metals, as lead and molybdenum, have been studied more extensively clinically than pathologically, and even yet it may be held to be undermined whether the action of the poison is upon the peripheral or the central apparatus. Dr. Popow has recently put on record the results of an anatomical investigation upon animals (chiefly dogs) poisoned by arsenic, lead, and mercuric, respectively (Virchow's "Archiv," 39, Heft 2), and in most cases he was careful to administer the poisons in varying quantities, so as to contrast the effects of acute and chronic poisoning. The general result of his inquiry goes to show that marked changes of an inflammatory character occur in the spinal cord, both in the grey and white matter, under all these conditions. In acute arsenical poisoning the spinal cord was softened, the gray matter especially being reddened and swollen; there was proliferation of the nuclei of the blood-vessels, and an oedema of a peculiar hyaloid substance. The nerve-cells were swollen, their processes shrunken, and their protoplasm granular or vacuolated, while in the white columns the axon cylinders showed irregular thickenings. In chronic poisoning it was difficult to discriminate between the two portions of the cord, the divided surface having a yellowish-red color throughout; the walls of the vessels were thickened; the nerve-cells vacuolated, or shrunken and pigmented; while free pigment masses, representing traces of hemor- rhage, occurred throughout the sections. In other words, there is, in poisoning by arsenic, a central myelitis at first, and later a diffuse myelitis. Very similar changes were found in the spinal cord after poisoning by lead—namely, exudation from blood-vessels; a general affection of the nerve-cells, beginning as cloudy swelling, and passing into atrophy and pigmentation; and inflammatory swelling of the axon cylinders.

In mercurial poisoning, the early changes consist of hyperemia of membranes and of the cord, followed by hemorrhages, inflammatory exudation, and changes in the nerve-substance hardly differing from those seen in the other two cases. In each instance the peripheral nerves and the nerve-roots showed no alteration; so that the conclusion is that the paralysis, spasm, etc., characteristic of the toxic effects of these metals depend upon a central rather than a peripheral disturbance, all the degenerative changes described as occurring in nerves and muscles being strictly desmopathetic. —Lanecet.

HOMOEOPATHY.—In answer to a correspondent, who had proposed a test of homoeopathy in one of the London hospitals, the "Lancet" says: "Our correspondent does not seem to be aware that homoeopathy scarcely exists as understood by Hahnemann. Its most popular exponent in London has published a new doctrine of therapeutics, directly contradicting Hahnemann's fundamental principle. We published last week the suggestion of a Hahnemannian journal, to drop the word 'homoeopathy' out of existence, as the only means of averting the imminent dissolution of the school. We are quite aware that there is a section of the public that believe in homoeopathy; but they are attended by those who have abandoned all its essential principles while still retaining the name. The argument that homoeopathy only needs a trial is quite untenable. It has been on its trial eighty years—as long, in fact, as vaccination. While vaccination is accepted by the whole world of scientific and rational men, homoeopathy is without a chair in any university of Europe, and it is proposed by its own leaders to drop the very name. The attitude of scientific medicine to it ab initio is thus thoroughly justified. The attempt to take shelter under the name of Dr. Sydney Ringer is now rather a favorite device of homoeopaths. But it will not save either their scientific or their moral position. Dr. Ringer takes medicines as he finds them, and investigates their action in health and disease unhampered by authority, and he does not trade on a name."

A CASE OF DEATH FROM A WASP STING has just occurred in the person of Miss Arkwright, aged fifty-five, of Mark Hall, near Harlow, who died within half an hour after receiving the sting on her little finger. At the inquest it was stated that she fainted almost immediately after being stung, and never recovered consciousness. Dr. Day deplored that death ensued from syncope, produced from excessive pain caused by the wasp sting.—_Mel. Times and Gazette._

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from September 29, 1883, to October 6, 1883.—_Tilton, H. R., Major and Surgeon. Assigned to duty as Post Surgeon at Fort Wayne, Michigan. Par. 4, S. O. 183, Department of the East, September 28, 1883._—_Bcheenin, Louis, Captain and Assistant Surgeon. Relieved from duty at Fort Columba, New York Harbor, and assigned to duty at Fort Wads- worth, New York. Par. 5, S. O. 183, Department of the East, September 28, 1883._

NAVY INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending October 6, 1883.—_Sergeon F. L. DuBois, detached from Naval Rendezvous, Philadelphia, and ordered as member of the Medical Examining Board, Philadelphia._—_Reid, Lt., Passed Assistant Surgeon Charles W. Rush, detached from the Naval Hospital, New York, and ordered to the receiving ship Colorado, New York._—_Rondeau, Lt., Passed Assistant Surgeon M. D. Jones, detached from the Naval Hospital, Washington, D. C., and ordered to the Naval Hospital, New York._—_Miller, Lt., Passed Assistant Surgeon Richard Ashbridge, detached from the Naval Academy, and ordered to the United States steamer Swatara._

SOCIETY MEETINGS FOR THE COMING WEEK.—_Monday, October 15th: Medico-chirurgical Society of German Physicians._—_Tuesday, October 16th: New York Obstetrical Society (private)._—_Wednesday, October 17th: Northwestern Medical and Surgical Society (private)._—_Thursday, October 18th: New Jersey Academy of Medicine (Newark)._—_Friday, October 19th: New York Academy of Medicine._
Puerperal Haemorrhage, - Accidental Haemorrhage. — Haemorrhage from Lacerations of the Genital Canal.

Placentae Praevia. — Obstetric Haemorrhage. — Haemorrhage from Placenta Prævia.

Gentlemen: When you meet with a case of placenta praevia you must, in the first place, bear in mind that delivery can not be accomplished without a previous dilatation of the cervix, and, second, that the cervix can not dilate without causing a separation of the placenta, and, third, that separation of the placenta can not take place without haemorrhage. The subject for us to consider, therefore, is, how we can control the haemorrhage and get the cervix dilated as rapidly as possible.

Now, there is one thing I want to say in regard to the danger in these cases. Suppose you recognize the existence of placenta praevia during the early months of pregnancy—that is to say, before the seventh month. If the labor is terminated within this period, the prognosis for the mother is favorable, and the dangers are next to nothing, but after the seventh month they increase very rapidly. The prognosis for the child is always very doubtful.

If you are called to a patient who is having a haemorrhage, and, upon examination, you discover a placenta praevia, and you know that she is in the last months of pregnancy, some of the books tell you that your best plan of treatment is to put the patient on her back and keep her quiet in bed, and give her cool drinks and opium, and apply ice to the vulva, and so on, and then do nothing more but wait, and let your patient alone until labor-pains set in, and then you should be on hand to stand by her and render whatever assistance is necessary. This waiting plan is advocated for the sake of the child, and to allow time for overcoming the rigidity of the cervix, and so for these two reasons you are recommended to temporize, and let the woman go on to the end of pregnancy.

But there are some reasons why this plan is not expedient, even in the interest of the child. If the haemorrhage first comes on between the twenty-eighth and thirty-second week, the chances are that you have to deal with a placenta prævia centralis, and the chances of saving the child’s life in a placenta prævia centralis are in any case too small to allow of the least consideration. The haemorrhages in such a case are apt to be repeated, and so, even if the child escapes one, it may be killed by the second or third. There is, therefore, no excuse for temporizing here. But, if the hemorrhage comes on after the thirty-second week, if labor is induced and delivery then accomplished, the chances of saving the child’s life will be better than by letting the pregnancy go on, when the mother and child will both be subjected to the danger of a profuse haemorrhage coming on at some time when you are absent, and it may prove fatal before you can be summoned. For the safety of the mother, all experience is in favor of inducing premature labor, and the results of this treatment are much better than where the pregnancy is allowed to go on until labor sets in spontaneously. In the latter case the mortality is from one third to one fifth. But, out of seventy-four cases where labor has been induced at the first appearance of haemorrhage, the women have survived in seventy. Sixteen died sooner or later, four during labor, and the rest in the week following. Foreboding dilatation of the cervix was employed here. The induction of premature labor therefore seems to be advisable if the diagnosis can be made out clearly. You should not let the case go on, for fear of accident while you are away, while if you immediately induce premature labor you can stand by and watch the progress of your case from the beginning to the end. The trouble is, if you wait, that haemorrhage may come on and you may not be called in until it is too late to save the patient.

But suppose haemorrhage does occur while you are at hand, what shall you do? In the first place, you will be governed by whether the child is alive or dead, and further by the extent of the placental attachment, the length and condition of the cervix, the character of the pains, and the condition of the child, if alive. If you find the cervix long, narrow, and undilated, then introduce into the vagina a tampon, so as to completely fill it up. You may use any soft material for this purpose, and you should pack it in so as to crowd the cervix well up against the placenta, and in this way labor-pains are excited, and the blood is pressed out and coagulates between the cervix and placenta, and so prevents further bleeding. If you have the materials at hand, take pieces of cotton and soak them in water to which have been added carboh acid and glycerin, and then pack these very tightly into the vagina. Some prefer to use a rubber bag in the vagina, filled with cold water. While this is a useful appliance, it is rarely seen in this country, and you probably would not come across one when you wanted it, and so you will be obliged to use old linen or cotton rags, such as you can find in the house, to pack into the vagina. Keep a tampon in the vagina as long as the cervix remains long and narrow. But as soon as it is dilated so that you can introduce a Barnes dilator, this will be better; it will check the haemorrhage just the same as the vaginal tampon, and it will also stimulate the uterine to contract, and dilate the cervix. Three desirable ends are accomplished by this Barnes bag. It stops the haemorrhage, hastens dilatation of the cervix, and induces contractions of the uterine. When the cervix has so far dilated that the bag no longer fills it well, then inject more water so as to enlarge it, and repeat this as often as necessary. In this way you may expect, in a large proportion of cases, to dilate the cervix in a very short time. As the cervix dilates from above downward, by the time the os externum has reached the size of the top of a wine-glass the os internum is all dilated, and it is said you may then pro-
ceed to extract the child. But I have found that death occurs in a great many cases from rupture of the uterus from forcible dilatation of the cervix, and so I think it is best not to be in too much of a hurry to deliver, but wait until the cervix is fully expanded throughout. After dilating the cervix, the next thing to do is to rupture the membranes, provided the head presents, and then the head comes down and blocks up the lower uterine segment; and, if the placenta is now detached, the head presses against the cervical walls and so checks the haemorrhage. As you rupture the membranes, it is well to have an assistant press down with his hands through the anterior abdominal wall, so as to push the head down into the lower orifice of the uterus. In these cases it is proper to give ergot. The induction of uterine contractions in placenta praevia by means of ergot is exceedingly difficult to obtain. But, if you can bring them on thus, it is an advantage so far as the safety of the mother is concerned, and the safety of the child is not to be considered here. The induction of uterine contractions is a very good way to check the haemorrhage; and so after you have carried out the other indications of tamponing the vagina, introducing a Barnes dilator and rupturing the membranes, and forcing the head down into the lower cervical orifice, you should not hesitate to use ergot and then allow the labor to go on. If it does not follow a natural course, you can then put on the forceps and deliver. But, if, after the rupture of the membranes, there is no descent of the head, and the pains are feeble and the haemorrhage continues, you cannot wait longer, but should pass your hand up through the cervix and into the uterus, and so get hold of an extremity and bring the child down, and then the pressure of its body acts as a tampon, and checks the haemorrhage.

Now, the case I have supposed so far is one where the placenta is attached to the margin, or only to a slight extent over the cervix uteri—that is, what is called a marginal or a partial form of placenta praevia. When, however, you have a case of complete attachment of the placenta over the cervix, or a placenta centralis, there is not much chance for delay. If you find, upon examination, that it has an extensive adhesion about the os, the first thing to do is to sweep your finger around and detach the placenta from the lower uterine segment, for then the uterus retracts and the haemorrhage ceases. This treatment was first inaugurated by Simpson, of Edinburgh, who showed that, if the placenta were loosen from its attachments, the haemorrhage would cease, or be only slight. He introduced his hand into the uterus and removed the placenta entire in some cases, and the haemorrhage ceased at once. The uterus generally contracts after the placenta is expelled, but before this the haemorrhage is apt to continue. It has not been found best in practice to introduce the whole hand so as to completely detach the placenta, but rather, after the cervix has begun to dilate, it is advised generally to pass half or the whole of the hand into the vagina and then insinuate two fingers between the cervix and the placenta, and strip off the placenta to the extent of about two inches and a half all round. Of course, after this procedure there will be some haemorrhage from the torn vessels, but this will be kept within moderate limits by the retraction of the uterine walls, and this can be still further facilitated by introducing a Barnes dilator, which not only stretches the cervix, but at the same time acts as a tampon, and also as a haemostatic, if filled with ice-water. As soon as the cervix is dilated to a point where you can introduce the whole hand into the uterus, pass it up between the placenta and cervix; or, if this is impossible, then pass it directly through the body of the placenta, and seize a foot and deliver by the operation of turning. If the child happens to be in the transverse position, or with the head downward, then get an assistant to manipulate through the abdominal walls and push the child around until the breech and knees are brought as nearly in relation to the cervix uteri as possible, then rupture the membranes and catch hold of a knee and bring down the extremity, and so tampon the cervix with the child’s body and arrest further haemorrhage. All the preliminary tamponing of the vagina and cervix presupposes that the membranes are yet intact, for otherwise this measure would be of no use, because then you would get an internal haemorrhage into the uterine cavity, and this would be more speedily fatal than leaving the patient alone.

When you have a partial placenta praevia, detach that portion covering the os and bring it down against the cervical wall, and then compress it between a Barnes dilator and the cervix; the pressure stops the haemorrhage from the open mouths of the vessels, and you thus convert the case into a placenta praevia laterata. After the cervix is dilated, proceed as before.

After the child is extracted, the next thing is to see that the haemorrhage does not return. It is well, therefore, to have at hand some persulphate of iron and cotton in small swabs, and then, if the haemorrhage continues, introduce a speculum, catch hold of the cervix, drag it down with a pair of forceps, dip a piece of the cotton into the persulphate of iron, and rub the bleeding mouths of the vessels over with this. Having checked the haemorrhage, you must next look out for septic poisoning, which is very apt to occur now, for large soft plugs are liable to form in the mouths of the uterine vessels, and these act as sponges to soak up septic material from the decomposing lochia. So you must guard against this accident by frequent douchings of the vagina with antisepic fluids. So much, then, for placenta praevia.

Accidental Haemorrhage.

Now, it is possible for a haemorrhage to take place from a partial detachment of a placenta which does not occupy the lower zone of the uterus. When haemorrhage occurs from a placenta attached in the lower zone of the uterus, it is called unavoidable haemorrhage; but, if from the upper zone, it is called an accidental haemorrhage. An accidental haemorrhage may result from irregular uterine contractions, from accidents or violence, from straining in moving the bowels, or from mental causes, etc., but often we are unable to determine the cause. The haemorrhage may be at the central portion of the placenta, and then only a partial detachment may take place; but sometimes these haemorrhages are very extensive, and so cause a considerable
amount of detachment. The whole border of the placenta may remain unbroken, or it may give way in some part, and then the blood may dissect its way out and appear externally; or the blood may pass between the uterine walls and the membranes until the membranes rupture, and the blood then passes into the uterine cavity and is confined there, or the head may so block up the lower orifice of the uterus that the blood can not pass out, but will be arrested at the cervix uteri, and in these cases the hemorrhage will not appear externally. This is called concealed hemorrhage.

Internal hemorrhages are generally associated with painful uterine contractions, and an increase in the size of the uterus, and sometimes with a bulging out of a portion of its walls; and with these there will be other symptoms, such as sudden faintness, pallor, a weak pulse, vomiting, and other signs of internal hemorrhage in any part of the body. It is not always easy to distinguish between this condition and rupture of the uterus. But rupture of the uterus rarely occurs until after rupture of the membranes, and not till then does the hemorrhage take place; and after the rupture the uterus, as a rule, diminishes in size; and, finally, when the uterus ruptures, the child usually recedes from the pelvic brim. But none of these things occur in accidental hemorrhage.

The prognosis in these cases is very bad. Out of one hundred and seven cases collected by Goodell, the mother died in one half or more, while the lives of only six of the children were saved. I would make a distinction in the prognosis according to whether the hemorrhage was external or internal, for in the former case the diagnosis is less obscure.

I would now make no difference in the treatment of the two forms, for I believe, in either case, the best plan is to introduce a Barnes dilator. What we want is to induce uterine contractions, for, if the membranes are intact and the uterus is made to contract, the amount of hemorrhage that can occur must be small. The danger is that the blood will fill the relaxed uterus, or the space between it and the membranes, and so cause a bulging out of a part of its walls. But, if the uterus is firmly contracted down upon the ovum, there will be but a small space for the blood to accumulate in. These contractions are induced by the Barnes dilator, and at the same time it aids in dilating the cervix; and, as soon as dilatation is completed and uterine contractions come on, the danger is nearly removed. You should now rupture the membranes, and pass the hand up into the uterine cavity and catch hold of the child's feet; as you extract it an assistant should make compression on the abdominal walls and follow the uterus down, and so check any hemorrhage that might follow from the relaxation of the uterus. You must be careful not to rupture the membranes until the dilatation of the cervix is complete, for, if you do, the blood will continue to collect in the cavity of the uterus, and the danger will be no less than before.

Hemorrhage from Lacerations.

Ruptures of the genital canal, of greater or less extent, occur in nearly every case of labor; but in some cases they are very decided, and require immediate attention. We may have such a rupture of the perineum, or vagina, or vestibule, or cervix, or uterus itself, or of the synchondrosis or the symphysis pubis, or a fracture of any portion of the pelvis. Rupture sometimes takes place in the vestibule or the bulbous portion of the vagina, and in such cases a very profuse bleeding may take place. So, if you have a post-partum hemorrhage, and find the uterus firmly contracted, you can be sure that the blood does not come from the uterus, though you may not know where it is from, and sometimes in these cases it is from the vestibule. In these cases you can not take up the bleeding vessels one by one and tie them, but sometimes injections of cold water or applications of ice will check the bleeding. Some say you can use persulphate of iron here, but this sometimes will not stop the hemorrhage, even after it has been in contact with the bleeding surface for an hour or two; but, as soon as you remove the cloth wet with it, the bleeding starts afresh. In such cases it is best to simply put in one or two deep sutures, extending around the two sides of the laceration, and bring the bleeding points together; this will stop the hemorrhage at once, and with very little pain.

Lacerations of the vagina are not at all uncommon, especially in forceps deliveries where the forceps is put on so that the blades do not fit close to the child's head, but project beyond it and so make deep grooves in the vagina. Sometimes these are so insignificant as not to be noticed, or they produce only slight symptoms, and heal after a short while. If you keep the parts clean and the patient in bed, in many cases she will never know that the injury has existed. But, if the laceration is more extensive and in the upper portion of the vagina, it is a different thing. For, if the tissues in this vicinity are torn to any extent and left to themselves, sloughing will occur, and in this way the peritoneal cavity may be opened and your patient suddenly show signs of collapse, when, upon examination of the parts, you will find that the intestines have come down into the vagina. It is, therefore, a good plan, in all cases of post-partum hemorrhage, to find out where the bleeding comes from, and, if you find it is from the upper portion of the vagina, you had better pull the bleeding point down outside the vulva, and put in a few stitches and bring the edges together. If you do this, the hemorrhage will be but a trivial affair.

Laceration of the cervix in the vaginal portion is of quite common occurrence, either from excessive rigidity of the os, or because the presentation of the child was such that one half of the cervix bulged out and was subjected to too much pressure during delivery. If the laceration of the cervix is not associated with hæmorrhage, your attention will probably not be called to it, and in time it will heal up perfectly. I make it a rule, after the placenta is expelled, to pass my finger up into the vagina, so that I may know how far the cervix is torn, if at all. It is a great deal better to know of a laceration existing than to discover it only after your patient has had a chill, followed by fever, on the third or fourth day after delivery. If the laceration is left alone, the parts will heal, but the edges will not unite, and, if the patient has trouble from this source afterward, the edges will have to be brought together by an operation. If the laceration of the cervix is followed by much hæmorrhage
Original Communications.

ANEURYSM OF THE INTERNAL CAROTID;
LIGATION OF THE
COMMON AND EXTERNAL CAROTID
AND THE
SUPERIOR THYROID ARTERIES,*

By John A. Wyeth, M. D.,
SURGEON TO MOUNT SINAI AND ST. ELIZABETH'S HOSPITALS; PROFESSOR OF
GENERAL AND GENITO-URINARY SURGERY IN THE NEW YORK POLYTECHNIC.

This patient presents herself for treatment on account of
a swelling situated below the left ear, and at the angle of the inferior maxilla. She is sixty years old, a seamstress
by occupation, unmarried, and has had no children. Her
dadier died when she was a child, and she knows nothing of
the cause of his death. Her mother died from the wear
and tear of a long life of poverty, and not from any acute dis-
ease. She has ten brothers and sisters buried, and one sis-
ter living. Six of the deaths occurred in childhood.

From her family history we are led to expect in this
patient a delicate constitution—one which would show earlier
than usual the lesions of the arterial system so common to
advanced age.

She tells us that she has been temperate in her habits of
life in all respects. Taking her word, and she impresses
me as a reliable woman, she has had no serious illness; no
syphilis, no rheumatism, no renal malady, no protracted
fever. Certainly no signs of these disasters are present,
excepting one that is not pathognomonic.

She has had "sick headaches" at various times for many
years. She ceased to menstruate in 1873, ten years ago.
About that time she began to notice an unusual throbbing
in the region now occupied by the tumor, which was accom-
panied by a ringing in the ear of that side. Becoming
accustomed to these conditions, for the next few years she
paid little or no attention to the malady. About four years
ago she began to have a left hemianopia, which has often

seriously interfered with her comfort. Within the last two
years, and especially within the last four months, the swell-
ing has markedly increased, and the pain of the neuralgia
has been commensurate with the growth of the tumor and
pressure upon the neighboring nerves. In this emergency
she consulted my friend Dr. R. C. M. Page, who kindly
directed her to me.

Naturally we expect an aneurysm. As you examine the
tumor, be careful to make no forcible compression; not that
it is painful, but dangerous. Aneurysm in the tract of ar-
teries leading to the brain can not be too carefully handled.
The dislodgment of a coagulum might lead to dangerous and
fatal cerebral embolism.

Massage may be justifiable in aneurysm of the extremi-
ties, where clots may occlude the artery of exit and thus
induce a cure of the disease, but it is a procedure attended
with too great danger in the neck.

The diagnosis of this swelling is by no means easy.
An enlarged tonsil, tumor of the parotid (a frequent seat of
neoplasms), sub-maxillary or cervical abscess, fatty or other
tumor in contact with the arteries, are complications which
we must certainly consider. To the sight the tumor pulsates
with the jump of the carotid. The pulsation of the tumor
is synchronous with the radial pulse and carotid systole.

To the feel it is soft, elastic, and when the pulsation
comes it has a peculiar thrill or tremor. Inserting the finger
in the mouth, the tonsil is felt to be normal, although pro-
jected inward by the swelling. With the finger of the other
hand upon the tumor externally, the expansion of the tumor
with the systole is in both directions. We therefore exclude
a solid growth over the artery or an abscess which would
pulsate in only one direction—that of least resistance. The
exclusion of abscess or other cyst is proved by the aneu-
rysmal thrill. Since we conclude it to be an aneurysm, which
artery is involved? The vertebral, internal carotid, or ex-
ternal carotid, or one of its branches? Aneurysm of the
vertebral artery is extremely rare, and is almost always if not
wholly of traumatic origin. There is a scar just over the
posterior border and upper part of the sterno-mastoid mus-
cle, which suggests a wound, but the patient says it was
cased by a burn in her childhood, and that she is positive
she has never had a penetrating wound of the neck. This is
a strong argument against vertebral aneurysm.

Pressing my thumb firmly upon the common carotid,
which is pushed against the cervical spine, the pulsation in
the aneurysm ceases. If the vertebral were involved, all
the pressure possible at this point would not affect the
pulsation in the tumor, since the transverse processes effectually
protect it from pressure.

The aneurysm belongs, then, to one of the terminal caro-
tids, and since it is deep seated, pulsating more percep-
tively in the pharynx than externally, and since the puls-
ation in the facial is as strong on this as the other side, I
conclude that the internal carotid is involved. I propose
now to tie the internal carotid, if enough sound artery can
be found between the aneurysm and the primitive trunk; if
not, I will tie the common carotid at the crossing of the
omohyoid, the external carotid below the origin of the lin-
gual, and the superior thyroid before it gives off the hyoid.

*This account is given in the words used by me before the surgical
class at the Polyclinic, where the case was made the subject of a clini-
cal lecture.
or mastoid branches. In this way the circulation in the sac will be arrested, excepting that which may occur through the circle of Willis.

Upon exposing the bifurcation of the common carotid and examining the first portion of the internal carotid, I discover that the seat of the aneurysm is in the course of the internal trunk, and that it will not be safe to tie this trunk. I therefore place a large thymolized catgut ligature around the external carotid, one fourth of an inch above the bifurcation and the same distance below the origin of the lingual. When I tighten the ligature, which I shall not do until the common carotid is secured, I do not intend to divide any tunic of the artery, but simply to draw it tight enough to occlude the vessel and hold it so until permanent occlusion results from the inflammation caused by the ligation, which inflammation produces proliferation of the endothelium and other protoplasm-making cells. This process alone leads to occlusion.

The ligature which I pass around the common trunk is the sciatic nerve taken from a calf about two months old. It has been kept one year in five-per-cent. carbolic-acid solution. It is about three millimetres (one eighth of an inch) in thickness. Drawing the loop until pulsation in the tumor ceases, a double knot is made; the two ends of the nerve are then tied with a small catgut, to prevent slipping, cut off, and left in the wound.

The ligature around the external carotid is next tied, and, lastly, that around the superior thyroid. The ends are cut off one fourth of an inch from the knots, and the wound is thoroughly washed with a five-per-cent. carbolic solution; a drainage-tube is inserted, which leads from the deepest to the most dependent point. The wound, with the exception of the lower angle, where the drainage-tube makes its exit, is closed with catgut sutures. Eight or ten layers of carbolized gauze, held in place by a gauze bandage around the head and neck, complete the dressing.

Carbolized, broad, tape-like animal ligatures have lately been introduced into surgery and used with invariable success, the credit of which is due to the distinguished English surgeon, Mr. Richard Barwell. This gentleman has tied a number of the larger arteries with ox-aorta ligatures. I know of no one who has used nerves for ligatures in operating upon human beings excepting myself. I have tied the carotid once before in this manner, and successfully.* One other carotid and one subclavian, with the ox-aorta, complete the record of my experience with the broad animal ligatures. Experiments upon animals with these ligatures have satisfied me that they are reliable and safe.

[Note.—The subsequent history of the case is short. The wound healed quickly, discharging a small quantity of pus through the drainage-tube. The pulsation in the aneurysm ceased entirely on the eighth day after the operation. The patient was able to go out of doors in the fourth week. There were no alarming symptoms developed. No hemorrhage. The aneurysm, which was about one by two inches in diameter, has diminished in size until it is scarcely appreciable. The patient is perfectly well, and has not had a hemiangia since the operation.]

A CONTRIBUTION TO THE TREATMENT OF CLUB-FOOT.

BY CHARLES F. STILLMAN, M. D.,
NEW YORK.

There has been a want in surgery for a light and effective apparatus for weak ankles when associated with inverted feet, for the less severe forms of talipes varus, especially when due to infantile paralysis, and for the after-treatment of such cases as have been subjected to operation. There are three tendencies in the deformity which should be combated by such an instrument in order to render it effective as a curative agent.

These are, 1, adduction, or local inversion at the ankle; 2, supination, or turning under of the foot, the ankle giving way externally; and, 3, contraction of the posterior muscles by which the os calcis is drawn upward, thus forcing the astragalus forward and causing prominence of the metatarsal bones on the dorsum of the foot.

When a case presenting these symptoms comes to the surgeon, it is generally passed over to the instrument-maker, who supplies a simple, heavy, retentive brace (see Fig. 1), with a strip passing up each side, which makes no provision for the first and third symptoms at all, and only partially succeeds in overcoming the second, while its unnecessary weight is detrimental (due to the presence of the extra strip on the inside of the ankle), in paralytic cases especially; or, perhaps, the patient may be provided with a "Hudson" brace (Fig. 2), recommended by Dr. Sayre,* which fulfills the second and third indications partially and the first not at all, and possesses the same demerit of weight.

It would seem, with an elastic strap on each side, that the third indication would be fully met by this brace, but this is to some extent defeated by there being no provision whatever for the production of local eversion of the foot, it being rigidly secured in the median line between the two side-strips. Where any foot is outwardly rotated as far as possible, it is thereby placed in the position in which the origin and insertion of the peronei muscles are most nearly approximated, and in this position the elastic force operates to best advantage in lifting the heel, because, if the foot is held at its extreme outward angle with the leg (extreme

eversion), and is seized under the ball and pushed upward, the metatarsal bones and astragali will be replaced in position, leaving no prominence on the dorsum whatever, and the os calcis will be pushed back by the astragali, thus causing a direct reversal of the process of the deformity; a result which can not be attained if the foot be held in the median line, as by the "Hudson" brace. There should be provision in the brace for outward lateral movement or eversion, as this is necessary for correct physiological treatment. To avoid weight, I use one side-strip instead of two, and that is placed externally, is articulated opposite the ankle, is riveted to the shoe beneath the arch, or to a metal insole if concealment be desired, and attached by two girths to the leg, one just below the knee and the other above the ankle, so that the muscular portion of the leg is not constricted or encumbered (see Fig. 4).

When a side-strip is worn on the inner side of the leg, it is apt to interfere with locomotion, leading to frequent falls, a result to be avoided by having it placed externally only—as in those being described. In order to fulfill the three indications already given, the single side-strip just described is to be fitted with two ratchets and an elastic strap. These ratchets are clamps, as shown in Fig. 3, and were described by me in the New York "Medical Record," as admitting either fixation at any angle or free motion. In this case we use them for fixation in preference to any other ratchet, both for symmetry and for ease of fabrication, the latter being an important item in the expense attending a brace.

One ratchet is to be placed just below the ankle for rotation (see Fig. 4), and allows that part of the brace below it to be thrown out and fixed at any angle with the part above; for when so fixed, and the shoe secured to foot and leg, any inversion tendency is combated by the entire brace, which thus acts as a powerful spring to keep the foot rotated outwardly. The second or pronation ratchet is to be placed where the side-strip passes under the shoe or insole (Fig. 4), and enables the surgeon to entirely prevent any tendency of the foot to turn under, for if the side-strip be clamped by it at an angle of about 45° outward from the foot, and then brought up against the leg, and secured by the girth, the foot will be turned in its long axis so that the patient will walk on the inner instead of the outer side. This effect may be varied by the ratchet in the side-strip, so that the brace may be anything from a simple vertical support to an agent for the production of valgus, so completely does this ratchet place the limb under the control of the surgeon.

The third and last indication is combated by the use of elastic webbing, provided with hooks, passing from an eyelet in the sole opposite the base of the little toe to a point on the side-strip at about the lower girth.

The rubber webbing is preferred to the rubber cord, as used by Sayre, on account of its durability, and because the cord is apt to wear through over the ball of the hook, necessitating frequent renewal.

We thus, by means of this brace, place the foot in a position to properly receive the weight of the body, and, if it is so received, the weight becomes an agent for the permanent cure of the deformity, tending to press the foot into normal shape; but if, instead of being rotated outward, the foot received this weight while inverted, or in the median line, the deformity would be increased.

In many cases it may seem preferable to allow a limited range of lateral movement of the foot, instead of having the eversion fixed by the clamp.

This may be secured by having a loose rotary joint, and attaching a coiled spring to the side-strip, whose power can be regulated by a cog and catch, so that it may be "wound up" to any desired degree of rotary power, thus combating the inversion by a constant elastic force, without impairing support.

By either of these forms of apparatus we can mechanically combat any of the simpler forms of deformity presenting the symptoms detailed in the commencement of the paper; and for the after-treatment of club-foot which has been subjected to operation they fulfill every indication.

The physiological point to which I wish to draw attention is the necessity of rotating the foot outward (extreme eversion) before applying elastic force, if complete reduction of an equino-varus or an equinovarus be desired. Whenever, in these conditions, the os calcis is drawn upward and the astragali projects, it is impossible to apply the upward elastic force advantageously in the median line until the foot is rotated outward, as the partial dislocation of itself prevents the normal degree of movement upward in the ankle joint. The foot should be taken in the hands of the surgeon and forcibly everted, and, after passing the median line, pronated; and it will then be found that the deformity can be relieved with much greater ease. It therefore follows that a brace, to be effective, should contain provision for these movements, and afterward afford fixation in the corrected position while not interfering with the normal
motion of the ankle, and that braces have not been done so in
the past may perhaps be argued as one of the reasons why
so many cases have been relegated to tenotomy, only to have
the relief thus obtained often followed by relapse and an
unsuccessful termination.

FLORENCE HOUSE, EIGHTEENTH STREET AND FOURTH AVENUE.

CASES IN
GENITO-URINARY PRACTICE.

BY H. RAPHAEL, M. D.,
ATTENDING PHYSICIAN FOR DISEASES OF THE GENITO-URINARY ORGANS AND
SYPHILIS, BELLEVUE HOSPITAL, OUT-DOOR DEPARTMENT.

Gonorrhoea with Ulecratior of the Neck of the Bladder, of
Four Months' Duration, cured by Blistersto the Peri-
neum. — Irritability of the Bladder due to a Neu-
rosis.

CASE I. Gonorrhoea with Ulceration of the Neck of the Bladder, of
Four Months' Duration, cured by Blistersto the Peri-
neum.—M. H., aged twenty-eight, single, cashier in a banking-house, had his first sexual inter-
course on December 28, 1881, and another on January 2,
1882. Three days after his second sexual intercourse he
began to feel pain and a burning sensation on urinating.
He immediately applied to his physician, who, on examin-
ing him, told him that it was the commencement of a gonor-
rhoea. The patient took the usual remedies for that dis-
ease, at first alkalies, and, when the inflammatory symptoms
had subsided, injections of sulphate of zinc were ordered.
The discharge soon diminished, but suddenly retention of
urine set in, with intense pain in the perineum, and, on exa-
mination, the physician said it was due to inflammation of
the right seminal vesicle. A consultation with a prominent
specialist in genito-urinary diseases was had, who confirmed
the diagnosis, and recommended a plan of treatment appro-
riate for the complication. The urine had to be drawn
off by the aid of a catheter for several days, the patient
being unable to empty his bladder. He gradually im-
proved, but about February 1st there was a recurrence of
the retention of urine, with pain in the region of the neck
of the bladder and perineum, requiring the use of the ca-
theter three times daily as before, and, upon examination,
his physician found that the left seminal vesicle was now
inflamed and swollen, the right being apparently in a nor-
mal condition. Under treatment directed to this compli-
cation the patient improved somewhat, but on March 20th
he began to suffer from frequent and painful micturition,
requiring him to urinate every forty or forty-five minutes,
the urine at the same time being loaded with pus, mucus,
and some blood, the latter fluid and clotted. The pains
were intense, especially toward the end of urinating, when a
few drops of bloody urine and coagula were expelled, pro-
ducing a flushing of the patient's face from nervous excite-
ment, accompanied by throbbing and heaving of the penis
and whole perineal region. To mitigate these excruciating
pains the patient was obliged to take morphine regularly
every four hours. In the absence of his regular consulting
physician, another eminent specialist was consulted, but
this gentleman was not disposed to agree to the diagnosis
of the first consulting and attending physician; a third
specialist in genito-urinary diseases was called in, and he
pronounced it a case of ulceration of the neck of the blad-
der, for the relief of which the patient was ordered to take
calcium sulphide and to continue the use of the morphine
for the relief of the pain, prognosticating the patient's re-
coverv in about three weeks' time. At the expiration of
that time, however, the patient was still in the same con-
dition, and it was now proposed by his consulting physicians
to perform an operation for the cure of the complaint, the
operation to consist of puncture of the bladder per rectum
and the introduction of a drainage-tube. This operation
the patient refused to submit himself to.

I first saw the patient on May 2, 1882, who had now
been ill for nearly four months, and his condition was as
follows: He was obliged to urinate every forty or forty-five
minutes; each act was preceded, accompanied, and followed
by intense pains, notwithstanding he was under the influence
of morphine, taking ten drops of Magendie's solution regu-
larly every four hours. The urine was thickly loaded with
pus, mucus, and blood, the blood being fluid and clotted;
often long, stringy clots were expelled, followed always by
prolonged throbbing of the penis and perineum, flushing of
the countenance, and general nervous excitation. His gen-
eral condition was poor, his appetite bad, and his sleep
much disturbed by the pain and frequency of micturition.
On examination per rectum I found a tender and painful spot
in the region of the neck of the bladder; there was also
pain on pressure of the bladder over the pubes. The intro-
duction of a gum-elastic bougie caused pain as soon as the
-tip of the instrument entered the membranous portion of
the urethra; the urine was highly alkaline in reaction.
Altogether I felt that there could be no doubt that it was a
case of ulceration of the neck of the bladder. I imme-
diately applied a blister over the patient's entire perineum,
and before it had entirely healed I put on another over the
same spot. The patient was put on a milk diet exclusively,
and I ordered him, in addition, to take carbonate of magne-
sium, with the result of causing the blood to entirely dis-
appear from his urine by the third day after the application
of the first blister. The patient was now able to hold his
water for two hours without inconvenience, and to void it
with but little pain. On the fourth day he gave up taking
morphine, and urinated only every three hours, the urine
being free from blood and containing only a small quantity
of sediment. On the sixth day he was able to hold his water
for four hours, and joined his family at dinner, and in an-
other week he was so far recovered as to be able to start
on an extended trip with one of the members of his firm
for the far West, and since then has enjoyed excellent health.

CASE II. Irritability of the Bladder due to Neuro-
sis.—D. K., merchant, aged thirty-five; married, father of
four children; never had any genito-urinary disease; pale,
and of a nervous temperament. About a year before he
consulted me he began to suffer from inability to hold
his water. At first he could hold his water for about two
hours, but of late he was obliged to empty his bladder every
half-hour; at night he micturated only every two hours. In hot or warm days he could hold his water for a longer period. A careful examination failed to detect either stone in the bladder, hemmorhoids, or any abnormality of the urine. His general condition was quite fair, and, aside from this complaint, he enjoyed pretty fair health. He had been under treatment for this complaint for nearly a year, which, by the advice of his physician, consisted mainly of a dose of morphine night and morning. Upon closer inquiry, the patient stated that he had suffered from sciatica some two years ago. I considered his case as a simple neuritis of the bladder, and gave him three drops of Fowler’s solution and three grains of quinine three times daily for a week, at the end of which time he reported that he was entirely free from his complaint.

Book Notices.

Third Notice.

The third volume begins with a chapter on the Diseases of the Absorptive System, edited by Holmes from the work of the late C. H. Moore. It is short, as such a chapter must necessarily be, and we fail to find any notice of lymphangiecis or lymphangionia. The chapter on Diseases of the Arteries is by the same author, and is equally short, including atheroma, acute arteritis, and occlusion from embolism or thrombosis. The well-known and admirable chapter on Aneurysm, by the editor, covers the next 125 pages of this volume and needs little or no comment. On the questions of treatment which have arisen since the last edition, it has been brought fully up to date.

Diseases of the Veins, originally by the late Mr. Callender, has been thoroughly revised by the editor, and under this heading we find phlebitis, hypertrophy and atrophy, and varicosities. Diseases of the Urinary Organs, Calculus in the Male, Lithotomists, and Calculus in the Female, are all from the pen of Sir H. Thompson, while a general chapter on Urinary Deposits and Calculi, by the late A. Poland, has been rewritten by W. F. Donkin. The kidney is included, and some very valuable matter has been introduced relating to its diseases and the operations of nephrotomy, nephro-lithotomy, and nephrectomy. Among the Diseases of the Bladder we find a special article on Thompson’s method of digital exploration through a perineal incision, and the articles on the prostate and urethra are both very rich in practical matter. The chapters on Lithotomy and Lithotrity embody the full experience of their author.

The two chapters on Venereal Diseases are by Henry Lee, and are quite richly illustrated with colored plates. Besides the ordinary matter found under this head, the author has devoted considerable space to such questions as “primary syphilitic inoculation without ulceration,” lymphatic absorption, inoculation modified by previous disease, twofold inoculation, and the hereditary transmission of the disease.

The Surgical Diseases of Women is from the pen of J. Hutchison, and deals only with the major surgical procedures, such as the operations of hysteroscopy, ovariotomy, the treatment of cancer, and of vesico-vaginal fistula and ruptured perineum. More space is given to Birkett’s article on Diseases of the Breast than to Diseases of Women, and it is correspondingly fuller, several pages being devoted to the anatomy, principles of diagnosis, and general therapeutics before beginning on the diseases proper.

The essay on Diseases of the Male Organs of Generation, by G. M. Humphrey, rewritten by Jacobson, is one of the largest in the book, and one of the most complete. The authors seem to have aimed at omitting nothing relating to the testis, and the result is a most comprehensive and valuable résumé of all our knowledge on this subject compressed into a convenient form for ready reference. The article on Hydrocele is equally complete, and a few pages are given to self-abuse, spermatorrhea, and impotence, with the malignant diseases of the penis.

The chapter on the Thyroid Gland, by Haward, is almost too condensed to be satisfactory. The chapter on Anaesthetics is by Lister, and is divided into three portions, one written in 1861, one in 1870, and one for the present edition. He publishes his own case of death from chloroform, but he holds to the use of that agent still. The article on Minor Surgery has been rewritten by Lyell, who also contributes the following one on Plastic Surgery. This latter is very complete, and the idea of embodying these operations in a separate article seems to be an exceedingly good one. Not only are the operations on the face described and figured in full, but also those on the bladder and penis, the operations for contracted cicatrices, and the best methods of skin-grafting.

The article on Amputation, by Lister, has been supplemented by one on Artificial Limbs by W. Watson Cheyne, in which many ingenious devices are figured; and the work proper closes with the editor’s essay on Excision of Bones and Joints. But, that nothing of any importance might be omitted, an Appendix of more than a hundred pages of fine type has been added, including Surgical Diseases of Children, Congenital Dislocation and Intra-Uterine Fracture, Rickets, Osteotomy at the Hip, Knee, Leg-bones, and Radius, Apneus (Asphyxia). Parasites, Venemous Insects and Reptiles, Surgical Diagnosis, and Regional Surgery, by such men as Holmes, Busk, Harley, Little, and Brodlaust. Some of the most valuable matter in the book is to be found in this appendix. The work closes with forty pages of index.

We have tried thus, in the briefest manner possible, to give the reader a general idea of the contents of this great work, and of the changes to be found in this edition. The length of time required for a mere enumeration of the contents is an indication of the amount of matter to be found in these three thousand pages of closely printed text. When we say that the book in this edition once more steps into the place it occupied twelve years ago, before more recent publications had left it behind, we say all that needs to be said. Holmes’s “Surgery” is still the surgery it was in our student days, when the expense of the five volumes was the only thing which kept every student from owning a copy; and Mr. Holmes has admirably succeeded in the task of bringing the work up to date. It has been our pleasant task during the past few months to welcome several important works of this kind in the columns of this journal. Ashhurst, Gross, Agnew, and Holmes have each seemed all that could be desired as a text-book. To choose between them would be an unnecessary if not a thankless task. All are good—wonderfully good, and should we be asked by the student which to buy, we should simply say buy as many of them as possible. No library is complete without them all, and in them all is contained everything in modern surgery.

Correspondence.

LETTER FROM BOSTON.

The Celebration of the One Hundredth Anniversary of the Foundation of the Medical School of Harvard University, and the Dedication of its New Building.

Boston, October 17, 1883.

In a previous letter a description of the new building of the Harvard Medical School has been given. The exercises of dedication were to have taken place last June, but this arrangement was prevented by the fire which occurred at that time. Now no traces of the accident are visible on the inside, and it takes a close observer to detect any blemish to the substantial exterior, the beauty of the building not being marred in the slightest. The committee of arrangements who had the management of the dedicatory exercises were Dr. J. C. Warren, Dr. H. W. Williams, Dr. J. C. White, Dr. W. L. Richardson, and Dr. W. H. Baker, and it was in great part due to the earnest and hard work of these gentlemen that the exercises were so successfully carried out to-day. About six hundred special invitations were sent out to subscribers to the building fund, and to distinguished people at home and abroad; and a general invitation was given to physicians through the State, though admission was only obtained upon presentation of a ticket to attend the exercises and inspect the building, which was thrown open for the occasion, except the dissecting-rooms, which were closed out of respect to the feelings of the ladies present.

The literary exercises were held in Huntington hall, Institute of Technology building. That portion of the hall directly behind the center of the stage was heavily draped with red plush, which served as a background for the three-quarter portrait of Professor Oliver Wendell Holmes, and the bust of Professor Henry J. Bigelow, which were to be presented to the school.

The order of exercises was as follows: At Huntington hall: Address by the President of the University; oration by Emeritus Professor Oliver Wendell Holmes; presentation of a portrait of Professor Holmes, by Dr. Francis Minot, in behalf of the donors; presentation of a bust of Professor Henry J. Bigelow, by Hon. Samuel A. Green, in behalf of the donors. At the Medical College: Prayer by the Rev. Andrew P. Peabody, D.D.; dedication of the new building to the purposes of medical instruction; Addresses: President Charles W. Eliot, in behalf of the corporation; Professor Henry W. Williams, in behalf of the medical faculty; Henry Lee, Esq., in behalf of the donors; reception of subscribers to the building-fund and invited guests, by the medical faculty; exhibition of the building. President Eliot traced the early history of the school, from the time when Dr. John Warren, Dr. Benjamin Waterhouse, and Dr. Aaron Dexter lectured in the basement of Harvard Hall and in a portion of the little Holden Chapel at Cambridge, down through its gradual growth to the present time, when its corps of instructors numbers forty-seven. He alluded to the admission examination, the advantages of the graded course, and the voluntary fourth year of study.

Then followed Dr. Holmes's address, which was the feature of the day. Never before has Holmes appeared to such advantage. In the course of the address, which was largely historical, he paid a glowing and deserved tribute to the achievements of the emeritus professor of surgery, Dr. Henry J. Bigelow. Another noteworthy feature of the address was the witty way in which the speaker threw ridicule, and at the same time censured, on the present Governor of the State for his exploits in attempting to arouse the wrath of the ignorant and the unthinking against the practical study of anatomy. The serious results to which such a stirring up of the dregs of society might lead were also dwelt upon, the burning of the great Alexandrine Library being held up as a warning.

Dr. Francis Minot, in presenting Professor Holmes's portrait, said:

Many alumni of the school, together with some of its present students, have desired that a permanent memorial of their beloved teacher, Professor Oliver Wendell Holmes, should be placed in the new college building, in token of their gratitude for the great services which he has rendered to many generations of his pupils. By his eminent scientific attainments, his sound method of teaching, his felicity of illustration, and his uniring devotion to all the duties of his chair, he inspired those who were so fortunate as to come under his instruction with the importance of a thorough knowledge of anatomy, the foundation of medical science. In the name of the alumni and students of this college, I have the pleasure of presenting to the medical faculty a portrait of Professor Holmes, to be placed in the college in remembrance of his invaluable services to Harvard University, to the medical profession, and to the community.

The Hon. Samuel A. Green, in behalf of the donors, presented the bust of Professor Bigelow. He said:

The pleasant duty has been assigned me, Mr. President, of presenting to you, as the head of the Corporation of Harvard College, in behalf of his many friends, this animated bust of Professor Henry J. Bigelow. The list of subscribers comprises many names, and includes nearly all the surgeons of the two great hospitals in this city; several gentlemen not belonging to the medical profession, but warm personal friends of Dr. Bigelow; a few ladies who had been his patients; and all the surgical house-pupils who had been connected with the Massachusetts General Hospital during his long term of service at that institution, so far as they could be easily reached by personal application. The bust is given on the condition that it shall be placed permanently in the new surgical lecture-room, which corresponds to the scene of Dr. Bigelow's long labors in the old building. It has been made by the eminent sculptor, Launt Thompson, of New York, and is a most faithful representation of the distinguished surgeon. It outlines with such accuracy and precision the features of his face, and the pose of his head, that nothing is wanted, in the opinion of his friends, to make it a correct likeness.

I need not in this presence of this audience name the various steps by which Dr. Bigelow has reached the high position which is conceded to him as freely and fully in Europe as it is in America; but I can not
CORRESPONDENCE.

Oct. 20, 1883.

forbear an allusion to some of his original researches. His mechanism of the reduction of a discolored fern by manipulation was a great discovery in surgical science, and follows as a simple corollary on the anatomical facts which he has so clearly and minutely demonstrated. His operation of rapid lithotripsy has deprived a painful disease of much of its terror, as well as of its danger. Nor should I overlook on this occasion his quick and ready discernment of the importance of Dr. Morton's demonstration of the use of ether as a safe anæsthetic, which took place at the Massachusetts General Hospital in the autumn of 1846. The discovery of this greatest boon to the human family, since the invention of printing, was fraught with such immense possibilities that the world was slow to realize its magnitude; but by the clear foresight and prudent zeal of Dr. Bigelow, shown in many ways, the day was hastened when its use became well-nigh universal.

Dr. Bigelow has filled the chair of surgery in the Harvard Medical School for thirty-three years, a period of professional instruction that rarely fails to the lot of any teacher, and he now leaves it with the honored title of professor emeritus. During this long term of service he has taught, through his lectures, probably not fewer than eighteen hundred students who have graduated at the Medical School, and, perhaps, seventy-five hundred more who have taken their degrees elsewhere; and by these thousands of physicians, now scattered throughout the land, those of them who survive, Dr. Bigelow is remembered as most eminently a practical teacher. Active in his profession, clear in his instruction, and enthusiastic in his investigations, he always had the happy faculty of imparting to his students a kindred spirit and zeal. Haud inceptus loquor.

At the close of these exercises the invited guests went at once to the new Medical School, where the Rev. A. P. Peabody, D. D., offered the dedicatory prayer, consecrating the building to science, humanity, and charity, to Christian tenderness and love, and to all the ministrances that can enrich humanity.

President Eliot then said: "In behalf of the President and Fellows of Harvard University, and of the Medical School, I declare this building to be devoted to medical science and the art of healing."

After further addresses by Professor Henry W. Williams and Colonel Henry Lee, a reception was given by President Eliot and the faculty to the subscribers to the building fund, and an elaborate collation was served. The floral decorations were numerous and beautiful.

In the evening the medical faculty gave a dinner at Young's to the invited guests.

LETTER FROM WASHINGTON.

The late Surgeon-General Crane.—The Question of his Successor.—The Surgeon-General of the Navy.

Washington, October 13, 1883.

Your issue of this date, which has just reached me, well expresses the sympathy of the medical profession here with their confrères of the army on the occasion of the death of Surgeon-General Crane. I will refrain from enlarging on the circumstances of his last illness; the one central fact that he is now no more is what we have to face. To say his loss is felt with unalloyed regret is something—indeed, very much—more than to utter a graceful sentence. It is not custom and propriety alone that dictate it; it reflects a genuine feeling, and one that is, I believe, universal among those who knew him, as well as among the medical corps of which he was the chief.

That another vacancy has occurred so soon in the office of surgeon-general perhaps stimulates the speculation that is never slow to mingle with our sense of bereavement—the query as to the succession. Even this republican country never falls on such an occasion to catch the spirit of the paradox, le roi est mort, vive le roi! and here in Washington, as everybody knows, not only pure politics, but all that pertains to the administration of the various branches of the public service, is most continually in the minds of the people. It is no wonder, therefore, that, while yet the fact of General Crane's death has scarcely had time to meet with perfect realization, gossip is found to turn upon the question of his successor.

There are several men whose names are high in the list concerning whom it may safely be said that their appointment would prove acceptable to the army, and it is gratifying to observe the general feeling of confidence that no unworthy choice will be made.

Bargaining and corruption have seldom cropped out in the management of our military affairs, and it is felt that in this instance there will be no exception to the rule. Without stopping to discuss the question of whether or not seniority should be rigidly followed in such a matter, it may not be out of place to call attention anew to the good results that have been the consequence of the contrary policy in the case of the navy. Prominent among the men who are named as likely to succeed General Crane are the assistant surgeon-general, Colonel Robert Murray, now on General Hance's staff, and Colonel J. H. Baxter, on duty here as chief medical purveyor. Among the four remaining colonels in the medical corps, the only other whose name I have heard mentioned in this connection is Colonel Charles Sutherland, the present medical director of the Division of the Pacific.

Of all these gentlemen, I hear Colonel Baxter most spoken of, and I am inclined to think that, on the whole, his succession to the office would be most acceptable. Certainly, his high social position would provide a tower of strength to the medical corps in case his appointment should be decided upon. Perhaps such an occurrence would be doubly gratifying to the profession at large, since it would seem like a piece of retributive justice to offset the insult to which he was subjected by the most audacious of the medical men who were in attendance upon the late President Garfield during his last illness, and like a fitting recognition of the manliness displayed by Colonel Baxter in foregoing the satisfaction he might have derived from publishing certain facts that were abundantly verified in regard to the circumstances under which the insult was given.

Turning from the army to the navy, I am reminded, as doubtless few of your readers need be, that Surgeon-General Wales's term is drawing to a close, and that, in all probability, a determined effort will be made by a number of malcontents to defeat his reappointment. It is on every account to be hoped that this opposition will turn out to be as impotent as it is impudent, for no one can deny that the medical corps of the navy has occupied a more creditable position under Dr. Wales's administration than ever before. However, I feel sensible that there is a limit to your indulgence in the matter of space, and I will therefore defer to a subsequent communication what I might say under this head.

Chlorophyll in Animals.—Some biologists have considered that chlorophyll in animals was due to the presence of minute parasitic algae; but this view, entertained by German physiologists, is opposed to various considerations. Chlorophyll has been found in a diffused condition throughout all the tissues, and not merely in the form of little globules, which might be considered as independent organisms. Mr. MacMann read a paper at the British Association in which he defined chlorophyll as that coloring matter or mixture of coloring matters which can be extracted from green leaves by means of alcohol and ether. He had proved that this green coloring matter was present in the intestines of invertebrate animals, and the conclusion at which he arrived was that all the characteristic appearances of vegetable chlorophyll are present in animals, and that such pigments were synthetically built up by and in the bodies of animals. —Lancet.
THE NEW YORK MEDICAL JOURNAL,  
A Weekly Review of Medicine.

Published by D. APPLETON & Co. 
Edited by FRANK P. FOSTER, M.D.

NEW YORK, SATURDAY, OCT. 20, 1883.

A QUARREL OVER THE MANAGEMENT OF A HOSPITAL.

It seems to be fated that in almost every hospital, sooner or later, the board of managers and the medical staff shall fall to quarreling. In most hospitals both these bodies are made up of intelligent and well-meaning men, and there seems to be no a priori reason why they should not work together harmoniously; nevertheless, an occasion for contention seems seldom lacking for any great length of time. While it must be acknowledged that the medical officers of hospitals, anxious to bring every appliance of their art into play in the prime work of healing the sick, are apt to fall into a chronic state of irritation at the prudence which denies them many of the agencies that are expensive—a prudence that they would rather term parsimony, and while it must also be admitted that they occasionally seek to rise above their proper function, and take a hand in the administration; still—and we say it not unkindly of our liability to be charged with partisanship—it is often the lay officials that forget their proper sphere, and for the time being lose sight of the fact that the chief object of the institution is to conduct disease to a favorable issue. The test of this statement is easy of application: at last, one of the two parties to any dispute of this sort has to yield the point. In the first instance, the doctors usually have to give way, because the power is vested in their opponents, but it is no uncommon thing for the latter eventually to confess themselves in the wrong by a reversal or a modification of their first decision. We think it susceptible of demonstration that the latter happens oftener than it fails to happen; and that is our test.

But, common as it is to find the lay power arrayed against the medical service, it is a rarity to encounter such a state of things as seems to obtain at present in the New York Infant Asylum, where, as is stated elsewhere in this issue of the journal, a chronic contention is going on in which manager opposes manager, and doctor opposes doctor. Such a spectacle is not uncommonly presented by institutions that are more or less fraudulent, but for a charity of the standing of the asylum in question it is almost an anomaly. Certainly, no one who feels any interest in the continued usefulness of the institution can fail to appreciate the misfortune that has overtaken it. The situation might, perhaps, be remedied within a reasonable period, were it practicable for outsiders to discern its merits; but the difficulty of doing so is rendered considerable by the fact that among the supporters of each side to the dispute are to be found both managers and medical officers on whose general sagacity, probity, and fair-mindedness the community has been accustomed to rely. We are inclined to think that the problem would be materially simplified if those who, in the present juncture, may be called the opposition would consent to bury what may reasonably be looked upon as a dead issue—namely, the past acts of the President, Mr. Clark Bell. It might be left an open question whether those acts had been not only strained and unusual, but also arbitrary and of the nature of usurpations, as well as whether they were the outcome of mistaken but well-intended zeal, or of some other motive less pardonable—all this, we say, might safely be left to take care of itself in the future, and those who have, perhaps not without reason, felt aggrieved on those points might still rally to the rescue of the institution from the danger it stands in of forfeiting the confidence of the community.

Meantime, the action of the East Chester Board of Health strikes us as supremely absurd. The idea of recommending the Grand Jury to proceed against an institution of this sort simply on account of its death-rate is preposterous. As well might the Government be indicted, were that procedure possible, whenever a regiment is decimated by an epidemic. If there is any element of truth in what the board alleges, the asylum has doubtless recognized the necessity of heeding the moral before now, and legal proceedings should not be thought of until the contrary has been proved to be the case.

THE PORRO OPERATION.

Dr. Robert P. Harris, of Philadelphia, has written voluminously and most instructively on the Ceasarw operation in its various modifications, as well as on a number of operative procedures that have from time to time been substituted for it. In his latest contribution, published in the October number of the "American Journal of the Medical Sciences," he seeks to rescue Porro's operation from the discredit that seems likely to be thrown on it by reason of its being confounded with certain operations that can not properly be regarded as modifications of the proceeding originally carried out by Professor Porro. He mentions no fewer than nine different procedures, as follows: 1. The true Porro operation, in which the stump of the cervix is secured in the abdominal wound. 2. Müller's modification, in which the uterus is drawn out through a long abdominal incision before being opened. 3. Müller's modification, the uterine section being made with a Paquelin's cautery. 4. The Muller modification with the constriction of the cervix effected by Esmarch's method. 5. The Porro operation, with the modification that the stump of the cervix is not secured in the abdominal wound, but is ligated and dropped. 6. Müller's modification intensified, so to speak, the uterus not being opened until after it has been entirely separated, the stump of the cervix being then treated as in Schroeder's method of abdominal myomatomy. 7. The Porro method with the constriction effected after the manner of Esmarch, and the stump dropped. 8. "The Müller ablation; uterus not opened; stump secured in the abdominal wound." 9. Removal of the uterus and ovaries after laparotomy for rupture of the uterus.

Dr. Harris admits that the first four of these procedures may properly be classed as Porro operations, making Müller's modification, the so-called "Porro-Müller operation," a variety; but
he aims at simplicity by reducing the five other operations to three, namely: 1. "Puerperal utero-ovarian amputations with the pedicle dropped in." 2. "Premature ablations of the gravid uterus, the fetus not being viable." 3. "Prévôt's operation," the last in the list of nine. To our mind, the number might be reduced still further to advantage, for, although Dr. Harris urges the distinction, we are unable to see why the fact of the stump being ligated and dropped should take a case out of the field covered by the term Porro's operation. It is argued that the fatality is greater in such cases, and that Porro's method should not be loaded down with their adverse statistics. This plea shows a commendable loyalty to Professor Porro's fame, but it seems to us illogical nevertheless. Moreover, the dropped-stump method may yet come to be the most successful, as has been the case with ovariotomy. While on this point, we can not refrain from the suggestion that some device may yet be hit upon by means of which a constrictor capable of being tightened from time to time shall be led down through the cervical canal and the vagina, thus doing away with the inconveniences of the clamp and the inefficiency of the ordinary ligature.

The two remaining classes—that in which a uterus that happens to contain a fetus is removed for other purposes than as a means of delivery, and that in which it is removed as an incident in laparotomy done on account of rupture of the organ—we should exclude altogether from any connection with Porro's operation. It should be understood that the idea was not original with Porro, for the operation had been done on the lower animals many times before he carried it out on the human subject, but none the less is he entitled to whatever credit may come from any operation that has for its fundamental element the removal of the uterus by any means whatever, and with no matter what modifications in the steps of the procedure, as a supplement to the Cassarean operation. Modifications that time shows to be of advantage should redound to the credit both of their inventors and of Porro, while those that prove useless or injurious will soon be dropped.

SIR ANDREW CLARK AND HIS CRITICS.

Amongs the features of American life that often lead to comment on the part of foreigners is the freedom with which our newspapers speak of individuals, and particularly of those of their affairs with which the public has little if anything to do. But this practice will soon cease to be peculiar to Americans, if any indication may be drawn from an article that lately appeared in the London "World." The article seems to be the eighty-sixth of a series with the general title of "Letters to Eminent Persons," and the particular article we allude to, signed "Kosmos," is addressed to Sir Andrew Clark, Bart., M. D.

It is not long since we chronicled Dr. Clark's elevation to a baronetcry, and on that occasion we quoted from the "Spectator" a remarkable piece of flunkeyism. Quite sharp is the contrast between the "Spectator's" vein and that which pervades the serio-comic homily in the "World"—serious in the liberties taken with a man who, whatever his social and professional distinction, can scarcely be said to be in politics; comic in the ridicule it ingeniously casts on him under the guise of a good-natured analysis of his career. The "Spectator" affirmed that Dr. Clark was "undoubtedly quite at the head of his profession," but it was barren of any more specific commendation than a reminder of the service he had rendered in persuading middle-aged men and women not to over-eat themselves [sic], and in showing them how much less food and wine and tea they ought to take.

"Kosmos" is not so amiable. He imputes Sir Andrew Clark's success to his knowledge of men, bis tact, and his ability to counterfeit omniscience, remarking that the opportunity that made him was the occasion of bis making an ingenious speech at the Mansion House when the cholera broke out in London, in 1866, before a meeting at which Mrs. Gladstone chanced to be present. He takes pains to remind Sir Andrew that he is not by any means a man who has done anything original in medicine, or shown himself to be a great physician; and then, after conceding that he has "played the part of a J. B. Gough or a Salvationist recruiting sergeant among the upper classes," quietly proceeds to knock the props from under whatever claim Dr. Clark may have made, or have allowed to be made in his behalf, to have acted on noble impulses in the matter, by hinting that at a certain period in his life he found it requisite for his own welfare to become a total abstainer, and that at a certain subsequent period he found that he could indulge in wine to some extent without detriment—wherefore he inculcated teetotalism for all the world at first, but afterward became more tolerant.

Whether or not such a sequence of events has really been at the bottom of Dr. Clark's course on the question of strong drink, we are unable to say, but this much we may say, that, if it has, it would betray nothing foreign to a kindly and high-minded man, and that "Kosmos's" dissection of so secondary an aspect of an honorable career is in the highest degree ungenerous, not to say impudent.

DRAM-DRINKING AMONG WOMEN.

Mcron has been said of late years about tippling as indulged in by women of wealth and social position, and, facts force us to admit, with a good deal of reason. Moreover, that women of the criminal or semi-criminal class included drunkenness among their vices has been well enough known. It is something of a surprise, however, to find an intelligent and painstaking observer, and one of the female sex at that, recounting the extent to which, as she infers, the working-women of so enlightened and prosperous a State as Massachusetts take up the habit of dram-drinking early in life, and as the first step in a career of vice if not of crime. And yet such is the purport of an elaborate analytical article in the October number of the "Quarterly Journal of Inebriety," by Lucy M. Hall, M. D., the physician in charge of the Reformatory Prison for Women at Shrewsbury, Mass.

This lady has examined into the facts in the cases of two hundred and four women committed to the prison—one hundred and thirty-two for drunkenness, fifty-six for offenses against
chastity and public order, and sixteen for crimes involving loss of property. As a result of her study of these cases, she comes to the conclusion that the associations into which young women are brought by working together in large numbers in manufactories ("mills") have a special tendency to lead to habits of intemperance. Many a girl, according to her showing, had no other temptation than the example set by some associate; and often one girl with a fondness for beer proved the ruin of numbers of her fellow-laborers.

This is certainly a melancholy picture, for the female mill operatives of Massachusetts are largely recruited from among the agricultural population of the State, a class far removed from any innate propensity to vice. It seems to us quite possible, since the author seems to have relied mainly on the stories told her by the prisoners, that their tales were not unvarnished—in short, that many of them took up habits of intemperance only as a secondary step in a downward career. Many a woman would be tempted to account for her intemperance (a fact she could not deny) by pleading the circumstances alluded to, while she would hesitate to confide to one of her own sex the vice that had preceded it. We are inclined to think, therefore, that the significance of the facts given in the article may not be quite so appalling as it appears to be at first sight.

**MINOR PARAGRAPHS.**

**THE COUNTRY BRANCH OF THE NEW YORK INFANT ASYLUM.**

Last week we alluded to an outbreak of diphtheria in the establishment at Mount Vernon. We are glad to be able to state now that in consequence the visiting medical staff has been strengthened by the appointment of several additional physicians, who, together with the other members of the staff, will visit the house daily during the continuance of the endemic. Our informant adds that the outbreak is now well under control. Nevertheless, the East Chester Board of Health is reported to have censured the managers severely. In addition, two members of the Board of Managers, Mr. Theodore Roosevelt and Mr. T. K. Gibbs, have published a statement setting forth their disapproval of the management of the institution for some months past, and intimating that the President, Mr. Clark Bell, is largely responsible for the unfortunate discord prevailing in the board and among the medical officers.

**CIDER AND ALCOHOLISM.**

At a recent meeting of the Association française pour l'avancement des sciences the fact was brought out that alcoholism was most common in those parts of France in which apples were produced in abundance, and the vine was not cultivated. M. Leudet, of Lyons, explained the fact by stating that the cider was distilled, yielding a spiritious liquor d'un très mauvais goût et probablement toxique. If this is the case, we can only say that our French friends have not yet learned the art of making "apple-jack" as it should be made.

**AN UNFOUNDED IMPUTATION ON THE PRESIDENT OF THE ACADEMY OF MEDICINE.**

In the "Boston Medical and Surgical Journal" for October 11th there appears a report of the meeting of the New York Academy of Medicine, held on the 4th inst. The bias of the writer is very apparent, and one statement ought not to be allowed to pass uncontradicted. Although probably unintentional, it is really a libelous imputation on the President of the Academy, which the writer no doubt will promptly correct. It asserts that, two gentlemen, "whose names had been used without proper authorization, having declined to serve in this capacity, an 'amended notice' became necessary." Both the gentlemen referred to had agreed, one to move and the other to second the amendments, and neither withdrew until after the first notice had been printed.

**THE LATE EGYPTIAN EPIDEMIC.**

Commenting on the report that Dr. Koch had found a cholera bacillus in his investigations in Egypt, the "Tribune" mentions the divided state of medical opinion on the bacillus theory of consumption, and adds: "Moreover, it is now well understood that the disease recently prevailing in Egypt was a local epidemic, and not Asiatic cholera." We should all feel grateful to the "Tribune" for settling the question.

**NEWS ITEMS.**

**INFECTIOUS DISEASES IN NEW YORK.—**We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 16, 1883:

<table>
<thead>
<tr>
<th>DISEASES</th>
<th>Week ending Oct. 9</th>
<th>Week ending Oct. 16</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Cases</td>
<td>Deaths</td>
</tr>
<tr>
<td>Typhoid fever</td>
<td>74</td>
<td>25</td>
</tr>
<tr>
<td>Scarlet fever</td>
<td>42</td>
<td>2</td>
</tr>
<tr>
<td>Cerebro-spinal meningitis</td>
<td>8</td>
<td>6</td>
</tr>
<tr>
<td>Measles</td>
<td>10</td>
<td>5</td>
</tr>
<tr>
<td>Diphtheria</td>
<td>29</td>
<td>4</td>
</tr>
</tbody>
</table>

It is gratifying to note that this table shows a diminishing mortality from all the zymotic diseases except scarlet fever, and a decrease of the number of cases reported even of that disease.

**YELLOW FEVER.—**Pensacola is now reported to be free from the disease, and there is said to have been no recent case among the shipping at Vera Cruz. A surgeon of the Marine-Hospital Service has been ordered to Brestow, Ala., to investigate the alleged outbreak mentioned in our last issue.

**M. Pasteur's CHOLERA COMMISSION has left Egypt to return to Paris.**

**AN UNQUALIFIED PRACTITIONER IN HARLEM.—**An individual named Sebastian Kunzig, living in One Hundred and Fifteenth Street, is under arrest charged with having caused the death of a man to whom he had sold a powder which he alleged to be an infallible cure for malarial disease. The sick man died soon after taking a portion of the powder, and Kunzig is held to await the action of the coroner's jury. There seems to be nothing to show that he has the slightest trace of a medical qualification, and he is, therefore, liable to prosecution even if acquitted of the offense for which he is now held.

**THE NUMBER OF PHYSICIANS IN AMERICA.—**We are informed by the Secretary of the Illinois State Board of Health that, by a typographical transposition on page 175 of the advance sheets of the section on "Medical Education and the Regulation of the Practice of Medicine," issued by the board, the total number of physicians in the United States and Canada was made to read "60,410," instead of 90,410; and the proportion of population to each physician, "900" instead of 600—the figures "6" and "9" having been accidentally transposed.

**ST. VINCENT'S HOSPITAL.—**On Thursday Mr. Lawrence Barrett and the company of the Star Theatre generously gave a
matinée performance of "Richelieu," the profits to be devoted to
furnishing the new wing of the hospital.

The University of Dublin.—Dr. Cunningham has been
made professor of anatomy.

Professor Lister, we learn from the "Lancet," was received
with great enthusiasm on the occasion of a recent visit to Pesth,
the demonstrations including a torchlight procession.

The Medical Society of the County of New York will
hold its annual meeting, for the election of officers, on Monday
evening, the 32d inst., at the hall of the Young Men's Christian
Association, Twenty-third Street and Fourth Avenue.

The Medical Society of the County of Westchester.—
At a meeting held last Tuesday, at Tarrytown, Dr. George J.
Fisher, of Sing Sing, read an exceedingly interesting paper on
Avenzoar.

The New York Obstetrical Society.—The annual election
of officers, held last Tuesday evening, resulted as follows: Presi-
dent, Dr. William M. Polk; First Vice President, Dr. Clement
Cleveland; Second Vice-President, Dr. Paul F. Mundé; Record-
ing Secretary, Dr. Frank P. Foster (re-elected); Corresponding
Secretary, Dr. Emil Noeggerath (re-elected); Treasurer, Dr.
Joseph E. Janvrin; Pathologist, Dr. Henry J. Garrigues (re-
elected); new members of the Committee on Admissions (to
serve two years), Dr. Bache McE. Emmet, Dr. Benjamin F.
Dawson, and Dr. Colin Mackenzie.

The Remains of Harvey were to be removed last Thursday
from their present resting-place, and placed in a sarcophagus at
the Harvey Chapel, provided by the Royal College of Physi-
cians.

A Daily Medical Journal has been started in Paris.

OBITUARY NOTES.

Frederick D. Lente, M. D., of Cold Spring.—Frederick
Divoux Lente, M. D., died at Cold Spring, N. Y., on Thursday
of last week, in the sixtieth year of his age. Dr. Lente was
a native of North Carolina, and received the degree of A. M. from
the University of North Carolina. In medicine, he was gradu-
ated from the Medical Department of the University of the
City of New York, in the class of 1849. After having served on
the house staff of the New York Hospital, he settled in prac-
tice at Cold Spring, where his experience as surgeon to the
West Point Foundry conspired with his great natural ability to
make him known as a surgeon over a wide section of that part
of the State. He soon acquired a large practice, and was
highly esteemed in the community in which he lived. At the
same time he made himself known favorably to the profession
throughout the country by numerous important contributions
to medical literature, many of which were published in this
journal. The more important of the latter were entitled: "Se-
dative Action of Calomel," "Intra-uterine Medication," and
"Treatment of Intermittent Fever by the Hypodermic Injection
of Quinine." The last-mentioned paper reported several hun-
dred cases, and is thought to have been the first publication on
the subject in this country.

Several years since, the state of Dr. Lente's health obliged
him to give up his laborious practice at Cold Spring, and for a
time he resided in New York, where he turned his attention to
gynecology. At one time he held a professorship in that branch
in the Medical Department of the University of the City of
New York, and was one of the assistant surgeons of the Wom-
an's Hospital. His failing health soon compelled him to make
another change, however, and for some years past he has spent
the winter in Florida and the summer at Saratoga. But he was
never idle; whether in Florida or in Saratoga, his professional
services were in request, quite as much at the instance of his
confrères as in consequence of his own exertions.

Dr. Lente was an accomplished therapist, and in every
respect a sagacious practitioner. He was much admired by his
professional brethren for his ingenuity and his fertility of
resource, he was highly esteemed as a consultant, and he was
beloved as a man. We learn that his death was due to cerebro-
spinal meningitis.

Letters to the Editor.

THE TREATMENT OF PULMONARY CONSUMPTION.

To the Editor of the New York Medical Journal:

Sun: Having had ten years of considerable experience in the
treatment of lung diseases, I desire to offer a few remarks on
the management of phthisis, and consumption of the lungs.

Andrew Clark, F. R. C. P., London, pronounces phthisis to be"the
assemblage and progression of symptoms which are due
to an ulcerative or suppurrative destruction of more or less
circumscribed non-inflammtory deposit in the lung." And "it is al-
most an axiom that tubercle per se does not kill. It is accord-
ing to the character of secondary complications that the future
of a case is determined." He divides the disease into "tubercular
phthisis, pulmonary phthisis, and fibroid phthisis.

Professor Niemeyer, of the University of Tübingen, the great
philosopher who died too soon, remarked that "the term tubercul-
ization has been productive of great confusion, and against it I have
long protested." "The treatment of consumption has made
great advance since recognition of the fact that the disease de-
pends, as a rule, upon inflammatory action, and is only now and
then due to neoplasm."

Professor J. Hughes Bennett, of the University of Edinburgh,
the most accomplished of European authorities, in Reynolds's
"System of Medicine," vol. ii, page 113, writes: "It would thus appear
that there is nothing essentially destructive or necessarily fatal
in phthisis, and that in all stages of the disease it may be
checked, and enable the individual to live many years subse-
quent. So far from being considered uniformly or generally fatal, it is admitted that treatment can in a great majority of
cases prolong life, while in many, the number of which is an-
nually increasing, a complete and permanent cure may be effected."

I remember well of having once seen a man enter the exami-
nation-room of Professor Alonzo Clark, of the New York Col-
lege of Physicians and Surgeons. A glance told him the con-
sumptive's tale, and, without a word, this most venerable and
distinguished of American physicians remarked: "As I came up
Broadway, across a house-front I read a sign—Consumption
be cured." Yes, that's so; consumption can be cured; but
whether the individual within at that establishment can cure
it, that's another thing. I can see no reason why incipient
phthisis can not be cured just as well as an ulcer upon the sur-
face of the body."

I desire to draw particular attention not alone to the very
clear and pointed quotations made, but to their very high au-
thority. Bennett, Niemeyer, Andrew and Alonzo Clark, are, in
this class of diseases, with Laennec and Louis, of France, the
most illustrious in the history of medicine.

Notwithstanding the now well-established facts in pathology,
and their clear therapeutic indications, phthisis remains the
pons asinorum of the profession. The modern doctrines are
thoroughly practical, most liberal, wholesome to the under-
standing, and full of hope to the afflicted. In my examinations
in the dead-house, I have seen lungs, as Bennett and others have,
containing many scars, cicatrices that tell the tale of former
loss of tissue. I believe the treatment of consumption to be as
perfect to-day as it will ever be, or need be. But, to get the
best results, treatment must be much more systematic than at
present, and more persistently carried out. The hitherto hope-
less character of the disease has made many careless in its man-
agement. And failure to convince patients of what is really
known and can be done for them has caused many of them to
seek the negative methods of homeopathy, the abomination of
patent medicine, and heartless, venal quacks.

There is too much medication in this disease. Advise patients
upon the laws of physiology and hygiene, and what little medi-
cine is needed, let it be conservative, and let it be mild. A ra-
tional, physiological management of this affection, based upon
the facts of pathology, would indicate nourishment as a matter
of primo importance. Give milk, cream, butter, eggs, olive-oil,
cod-liver oil, mush and milk, bread, and such other articles, light
and digestible, as judgment will permit. Do not derange the
stomach by acids, or sweet sirups for cough. Acids and all cough
sirups disagree, and had better never be given. When occasion
requires, I give pepsin straight, but never any of the proprietary
substitutes. To hold digestion good I consider a great point in
this disease.

I always insist on such kind and amount of exercise as will
suit the case. Especially is open-air exercise to be commended.
Never let a patient over-clothe, so as to make the skin delicate
and impressionable to the least atmospheric change, and, per-
haps, constantly sweaty and debilitating. Apply dry friction
daily to the skin of the whole body until it glows; and, when
the patient can bear them, daily salt-water baths are of great
service. They strengthen the skin, remove the cold-catching
tendency, and stimulate nutrition.

Keep the patient much in the open air, and his apartments
well aired. On general principles, I object to a change of climate
for most cases, because I know it often requires a person to be in
perfect health to stand acclimatization in a distant land. And
some of my acquaintances who have sought health in foreign
lands have died there. To become inured to another climate than
our own is often a severe strain. Give consumptives a dry
house and pure air in their native place, or let them remove a
short way, but seldom to a great distance. I have all my pa-
tients take breathing exercise, in this way: A breath is taken,
deep and full as possible, held as long as possible, and then very
slowly expired; and this is repeated for ten minutes thrice
daily. And, although the proceeding requires great care, I
sometimes use a Politzer inflator to clear the bronchial tubes,
and often follow it with a mild carbolized glycerin spray from a
Mattson continuous nebulizer. I think this does’good in allay-
ing irritation and troublesome cough. It is used with decided
benefit in nasal and laryngeal catarrh, and I think with benefit
in the bronchial catarrh complicating phthisis. Belladonna is
my stand-by in night sweats.

I always examine the spits microscopically to see the pro-
gress of my patient. I take the temperature regularly, in the
mouth as most convenient, to assist me in prognosis and treat-
ment.

RICHARD B. FAulkNER, M. D.

THE MEDICAL CLUBS OF BUFFALO.

306 Franklin Street, Buffalo, N. Y., September 26, 1883.

To the Editor of the New York Medical Journal:

Sir: In your issue of the 15th of September inst. your Buf-

dalo correspondent closes his letter as follows: “One of the

medical clubs of the city, I hear, has passed a resolution that
its members shall only call each other in consultation. It might
well be named the Medical Trades-Union.” There are, so far
as I know, but two medical clubs in Buffalo. I am a member
of one of them—The Medical Union; and, so far as that or-
ganization is concerned, the statement of your correspondent is
entirely without foundation. Perhaps he can himself answer for
the other club, as he is, “I hear,” a member of it.

W. W. POTTER.

THE JEFFERSON MEDICAL COLLEGE.

PHILADELPHIA, October 12, 1883.

To the Editor of the New York Medical Journal:

Sir: In your issue of this date appears a letter from your
Philadelphia correspondent containing two erroneous state-
ments. The first is, “the students, thus far, at Jefferson are less
numerous than last year.” The other is, “owing to the differ-
ent system of lecturing, the class is later in getting together.”
Both statements are comparisons with the state of fact at the
University of Pennsylvania. It affords us pleasure to hear from
your correspondent any facts creditable to the university. He
could not be expected to praise Jefferson, but certainly it is his
duty to assure himself of the correctness of any statements made
about this college in a letter to your journal.

Very truly,

ROBERTS BARTHOLOW, M. D., Dean.

* * It happens that the author of the letter complained of
is an alumnus of the Jefferson Medical College, and a gentleman
far above the suspicion of entertaining an animus against that
institution, even if it were not his alma mater.

THE NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held October 18, 1883, the President,
FORDYCE BARKER, M. D., LL. D., in the chair.

The report of the librarian having been read by Dr. E. Dar-
winn Hudson, and accepted, the President announced the special
order of business for the evening to be the continuation of the
consideration, in Committee of the Whole, of the amendments
to the constitution and by-laws proposed at the last meeting.

IN COMMITTEE OF THE WHOLE, Dr. Ellsworth Eliot in the
chair.—Dr. AUSTIN FLINT, Jr., said that he did not wish to ob-
struct or oppose the discussion of these proposed amendments
in Committee of the Whole, but thought, as he had said at the
last meeting, that there was no necessity or reason for their
discussion, either in Committee of the Whole or before the Acad-
emy. He had not been able to see any reason why a scientific
paper was not prepared for the last meeting—it might have
been done under the notice that was sent out. The remarks
made at the last meeting by the gentleman who moved the
amendments [Dr. Edward J. Keyes], and by the gentleman who
seconded them [Dr. Alfred L. Loonis], he believed then, and he
believed now; were not in order, because properly there was
nothing before the Academy. He repeated that he was not
now speaking in opposition to the course of the meeting, but
the spokesman of a certain number of Fellows of the Academy who
believed that the interests of the Acad-
exy could best be served by maintaining its present by-laws in
regard to the matter of ethics, and who were unal-
terably opposed to the amendments in toto. The plain in-
tention of the proposed amendments was to eliminate from its constitution and by-laws everything relating to ethics; the result of their adoption would inevitably be to deprive the Academy of all disciplinary power, to do away with its right of representation in other societies, and to reduce it to the rank of certain organizations, such, for instance, as the Medical and Surgical Society and other societies, which, while they doubtless did good work, did not stand before the profession in the attitude to which this Academy aspired, and which it had always hitherto maintained. It was useless to discuss the amendments, for every one in favor of the old code would vote against them, and no amount of eloquence would convince those who opposed that code. The ethical question was what he supposed the supporters of the amendments had chiefly in view, and he did not imagine that they laid much stress on those of the amendments which did not affect the matter of ethics; nevertheless, as a matter of some importance, he wished to call attention to the detriment that might ensue to the Academy by reducing the quorum in the Council, as that measure would increase the power and the responsibility of a few individuals—it would make it possible for three individuals to dispose of matters of the utmost importance. At the last meeting he had, for the sake of regularity, made his motion that the amendments should take the usual course, and had protested against any amendment of that motion; but the President's ruling had been against him. He hoped that the rulings tonight would be different. This was the first time in the history of the Academy that any proposed amendments to the constitution or by-laws had been brought before the Academy without having first been submitted to the Council; and never before had a recommendation by the Council failed to be agreed to. In this instance the Council's recommendation has not even been accepted or acted upon in any manner. The idea that the amendments could possibly secure a three-fourths vote was ridiculous. Discussion was therefore useless, and he moved that the committee now rise. Seconded.

The President ruled that the motion was not debatable.

Dr. D. B. St. John Roosa appealed from the decision of the President, and, the appeal having been seconded, the sense of the meeting was taken, and the President's ruling was sustained.

The motion to rise was then put and carried.

The President then resumed the chair.

Report of the Committee of the Whole.—The chairman of the committee reported that the committee had sat and risen. The President ruled that the chairman of the committee had not properly reported the action of the committee, since he had not reported the resolution adopted by the committee at its previous session [see the journal for October 6th, page 388].

Dr. Flint, Jr., appealed from this decision, and the President's decision was sustained.

At the request of the President, Dr. Wesley M. Carpenter, Secretary of the Committee of the Whole, then read an extract from the minutes of the committee's session, including the resolution alluded to.

Dr. Flint, Jr., moved that the report of the Committee of the Whole be laid on the table. Seconded.

Dr. Roosa and four other Fellows called for the ayes and nays.

The President announced that the register would be used in calling the ayes and nays.

Dr. Flint, Jr., objected, and stated that the ayes and nays ought to called from the roll.

The President repeated his ruling.

Dr. S. S. Purple remarked that, with the exception of the meeting before the last, this was the first instance in which the register had been used for calling the ayes and nays.

Dr. Flint, Jr., asked to have his protest entered on the minutes, and appealed from the ruling of the President.

The President's ruling was sustained.

Dr. Flint, Jr., called for a division.

The President appointed Dr. Henry D. Nicoll and Dr. Charles Carroll Lee tellers, who reported that the President's ruling was sustained by a vote of 88 to 84.

The President then announced that opportunity would now be offered for those who had not signed the register to do so before the vote was taken.

The vote on the question of laying the committee's report on the table was then taken, and was declared lost by a vote of 102 to 115.

Dr. Alfred L. Loomis moved that, when the vote on the adoption of the amendments as they now stood before the Academy was taken, it be taken by ballot. Seconded and carried.

Dr. Loomis then moved that the meeting now proceed to the ballot. Seconded.

Dr. Acstix Flint, Sr., moved, as an amendment to Dr. Loomis's motion, that the amendments be indefinitely postponed. Seconded.

On this amendment Dr. Flint, Jr., and four others called for the ayes and nays.

The ayes and nays having been taken, the amendment was declared lost by a vote of 94 to 117.

Dr. Loomis then moved that the meeting now proceed to ballot on the adoption of the amendments. Seconded and carried.

The President appointed Dr. Henry D. Nicoll and Dr. Daniel Lewis tellers.

The vote on the adoption of the amendments, as declared by the tellers, was as follows: Ayes, 121; nays, 92. The amendments were therefore declared lost, a three-fourths vote being necessary for their adoption.

Having declared the vote, the President said:

I beg the indulgence of the Academy only for a few moments. Duty and honor demand that every member of an organization like this Academy, with its high scientific aims and joint stock property necessary to make those aims attainable, should cheerfully yield to the will of the majority. No one can doubt that it was with pain and regret that I announced the failure of a three-fourths vote to adopt the amendments, which I regarded as most important for the future of the Academy. Having given my reasons for this belief in a letter addressed to every Fellow, and having at the last meeting still further explained my views, but having failed to convince a sufficient number to secure their adoption, I bow to the decision. No one can assert that I have sought to secure my end by personal influence or personal solicitation. I have felt that this matter should be left to the intelligence and judgment of such a class of men as constitute this Academy, unbiased by passion or partisan feeling. I am well aware that it demands a higher tone of principle, and a more noble magnanimity, to cheerfully acquiesce in the will of a minority, but I now earnestly beg of all to forget, so far as this Academy is concerned, all past controversies—many of which, I am convinced, are not so much difference as to principles as differences in regard to details—and that all should unite in earnest work for this Academy in its high endeavors to advance medical science, to support and increase this important library, for which so much has been done in the past by most liberal benefactors, and to keep up the Journal and circulating departments. For my own part, I can only promise for the future what I have sought to give in the past—my best efforts in this direction, not only while I have the honor to hold my present position, but ever after.

Dr. Loomis said that, to prevent any repetition of the con-
tention that had lateiy disturbed the harmonious working of the Academy, he would move to rescind the following preambles and resolutions adopted by the Academy at its meeting in April last:

Whereas, The New York Academy of Medicine adopted in its by-laws, as its standard of medical ethics, the Code of Ethics of the American Medical Association; and

Whereas, Each newly elected member of the Academy is required to sign its constitution and by-laws; be it

Resolved, That the Committee on Admissions is hereby instructed to report to the Academy for election as resident Fellows no physician who is known to the committee to be in opposition to the code of the Academy, and who, as a consequence, can not consistently sign the by-laws of the Academy.

Resolved, That these instructions to the Committee on Admissions be continued in force until the American Medical Association shall have modified or repealed its code of ethics, and such modification and repeal shall have been adopted by the Academy, or until the Academy shall have modified or repealed its by-laws referring to medical ethics.

The motion having been seconded by Dr. Roosa, Dr. Loomis supported it by urging that we were not here to-night to vote on the matter of codes of ethics, but to decide upon measures involving the welfare of the Academy. Therefore, he urged that we should all unite to repair the damage that the passage of the resolutions had inflicted. Otherwise there might be a division of the profession in this city—there might be two Academies—which God forbid! The resolutions adopted last spring had acted as fire-brands, and to-night a majority had virtually repudiated them.

Dr. E. C. Harwood handed in a written personal explanation of his having declined to vote on Dr. Flint, Jr.'s, resolutions last spring. For his course on that occasion he had been charged with cowardice, inconsistency, etc. His reason for declining to vote on that occasion had been that he construed the resolutions as subversive of the action previously taken by the Academy on motion of Dr. Flint, Sr.

Dr. Flint, Jr., maintained that Dr. Loomis's motion was out of order, the action of the Academy last spring having been such as not to admit of reversal. The President ruled that Dr. Loomis's motion was in order, because there was a difference between rescinding and reconsidering.

Dr. Flint, Jr., appealed from the President's decision, and referred to the rules of order.

On appeal, the President's ruling was sustained.

Dr. Roosa spoke in favor of Dr. Loomis's motion, alleging that the action taken last spring had been taken in a packed meeting, the excuse for packing the meeting being that the anti-old code party had packed the meeting of the State society, at which the new code was adopted, which latter action he entirely denied. The action taken by the Academy last spring had not been justified by anything done by the anti-old-code party.

Dr. C. A. Agnew favored Dr. Loomis's motion, stating that the action of the Academy last spring was in violation of those portions of the constitution and by-laws appertaining to the requirements for admission to fellowship. It was, therefore, in the nature of an amendment, and, due notice not having been given, it was null and void. The meeting had been packed by means of a secret notice sent to those favorable to the resolutions, of which notice he now had a copy in his possession. [Tremendous applause.]

Dr. Flint, Jr., stated that he was quite willing, for his part, that certain Fellows of the Academy who offered their resignation at the meeting last spring should now be allowed to withdraw their resignation; but he thought it no more than decent that those gentlemen should ask the privilege.

Dr. Agnew, in reply, read the following from Art. VII: "Sec. 3. No resignation shall be valid until accepted by the Academy."

A motion was then made to adjourn. Seconded and lost.

Dr. Henry G. Piffard moved the previous question. Seconded and carried unanimously.

Dr. Loomis's motion was then put and carried.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held September 13, 1885, the President, Dr. Tyson, in the chair.

A VERY LARGE ULCER OF THE STOMACH WITH UNUSUAL FEATURES.—A specimen was presented by Dr. Charles W. Dukes, who said: The specimen came from the body of a patient of Dr. Edward L. Anderson, who had had Dr. J. H. Musser see her in consultation during life, and who asked my assistance in making the post-mortem examination because of Dr. Musser's temporary absence from the city. To the clinical notes of Dr. Anderson and my notes of the autopsy Dr. Musser will no doubt add his own impressions of the case, which has appeared to me to be of singular interest and instructiveness. The following are Dr. Anderson's notes:

Mrs. M., aged thirty-five years, the mother of five children, one of whom died of stricture of the pyloric or cardiac end of the stomach.

Both her parents died before their twentieth year.

May 12, 1883.—At my first visit she was confined to bed, and stated that since the birth of her last child she had not been well, having more or less dyspepsia, and growing steadily worse for the last six months. She complained of a constant burning pain in the region of the stomach which nothing seemed to relieve. She vomited daily, sometimes immediately after a meal, but often not until evening, when it seemed to her all the food she had taken during the day would be ejected. The matter vomited was intensely sour, dark, and frothy, having the appearance of yeast. There was always pain after vomiting, and at all times there were irregular pains over the abdomen. She was anemic, emaciated, and had a weak but regular pulse. Upon physical exploration, I could find no tumor. Her heart and lungs were normal, and, as I afterward learned, the urine likewise. The abdomen was resonant. She was placed on a milk diet, with pepin and ten drops of sulphuric acid every three hours. She took two quarts of milk daily, and did not vomit until the 23d of May—a period of ten days. On this day she vomited but a small quantity of food. May 23d, the period of her menstruation (though not menstruating from April until the time of her death), she ate a richer for supper on her own responsibility. This indiscretion brought on an attack of vomiting and sufficient prostration to occasion considerable alarm to her family, and cause them to send for me. I found her much exhausted, only able to speak in monosyllables, with the pulse 104 and the respiration 40. She complained of intiue burning pain in the stomach. External heat and sulphuric acid internally gave relief. This was the first time I was able to see the vomiting matter, and I found it to be digested blood, about two quarts in amount. Dr. J. H. Musser kindly examined the material microscopically, and found blood-corpuscles, pus globules, and epithelial cells. I was told she had vomited similar material prior to my first visit. The vomiting was repeated on May 25th, 26th, 27th, and 28th, and several times there were free hemorrhages. She was treated with bismuth and carbonate acid, with enemata of milk, whisky, and eggs, and injections of cod-liver oil. Hemorrhage occurred again on June 6th, 7th, and 8th. On June 10th Dr. J. H. Musser saw the case in consultation. He thought he detected a tumor. We came to no positive diagnosis, but wavered between carcinoma and ulcer. It was only when the patient was placed in the knee-elbow position that a tumor could be felt, and this a little to the right of the median line. The treatment was changed to one drop of tincture of hematin every twenty minutes, and a pill containing a quarter of a grain of oxide of silver three times daily. June 17th and 18th hemorrhages again occurred, but from this time until her death, about six weeks later, there were no more hemorrhages, also little inclination to vomit, and very
be noticed that he was jaundiced, and that there was a lump (or swelling) in his abdomen. Upon admission to the hospital he was much emaciated, and very febrile. Skin and conjunctiva intensely jaundiced, of a deep saffron hue. There was marked bulging noticed in the right hypochondriac and epigastric regions. The tumor, which could be plainly felt through the thin abdominal wall, was found to extend four inches below the xiphoid cartilage and two inches to the left of the linea alba. The mass occupying the right hypochondriac region was found to be distinctly nodulated, and very hard. Some of the nodules appeared to be umbilicated. The patient presented a markedly cachectic appearance; tongue thickly coated with a dirty yellowish-brown fur; his bowels were constipated, and there was anorexia. Purgation failed to influence the size of the tumor. The patient complained of insomnia, but did not seem to suffer much. Mental action was sluggish. He became rapidly weaker, and for fully a week before his death, it was noticed that his extremities were very cold, and quite three days before death his pulse had become so weak as to be almost imperceptible. Death finally occurred on August 15th.

The post-mortem examination was necessarily a hasty one, as the body was removed from the hospital within two hours of the patient’s death. The new growth appeared to involve, however, only the liver and the pancreas. The common bile duct was completely occluded by a hard nodular mass which had its apparent origin in the pancreas. Above the occlusion the cystic duct and the gall bladder were distended with dark olive-green bile. The liver weighed five pounds six and a half ounces. Sections of the organ showed complete infiltration with cancer nodules, and little or no normal hepatic tissue could be seen. The spleen was markedly atrophic, weighing one ounce and a half. The kidneys were deeply stained with bile and seemed somewhat contracted. The heart was very small, and its muscular tissue flabby.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held October 4, 1883, the President, R. A. Cleeman, M. D., in the chair.

Cesarean Hysterectomy.—Dr. W. H. Parish reported a case of what is known as the Porro-Müller operation, and showed the specimens, consisting of the uterus, a portion of the abdominal wall (showing the wound united, with the stump of the cervix at its lower angle), and the external genitals, together with the mons Veneris, the vagina, and the bladder. The ureters were found entirely free.

Sallie Smith, a deformed dwarf, applied for admission to the Philadelphia Hospital in April, 1883. One of the internes placed her among the pauper women of the out-wards of the almshouse. There all the conditions surrounding the dwarf were such as to contribute to her physical deterioration. The women in that portion of the institution are unduly crowded, the ventilation is entirely inadequate, and the food of a character unfit for a pregnant woman. Her presence in those wards was unknown to any of the visiting obstetricians of the hospital until June 15th, when Pauline Root, M. D., one of the internes, ascertaining her pregnancy and her surroundings, conveyed the information to me. I at once had her transferred to the obstetric wards, where she was specially provided for, and her condition carefully investigated. She was a native of Philadelphia. She was unable to give her age—although dwarfs usually appear to be older than they actually are, yet, from what could be learned of her past life, from evident aterhonia of her blood-vessels, and from her appearance, I concluded that she must be over forty years of age. Her parents were poor, were born in Ireland, and died in this city during her early infancy. She had been told that her father died of heart disease, and her mother of insanity at the menopause. She did not know how or by whom she was cared for during her early childhood. She attributed her deformities to a fall supposed to have been received when she was a very small child. She was unable to walk until she was seven years of age. Her occupation, from the time she was first able to work, had been that of a house servant. Menstruation began at sixteen years, continued at the usual periods, but rather profusely, until the begin-
PROCEEDINGS
concluded but, the yet I and

The tubes were imperfect, and inulin was added to the disease of the kidneys, to which I shall again refer. She was pregnant for the first time. The date of the last menstruation was given by her differently at different times. At one time she gave the 1st of October, at another time the middle of October, as the date when menstruation last ceased. She felt movement of the child about the middle of February, though she was also uncertain in reference to the date. The fundus uteri reached nearly to the umbilicus, and I concluded that the full period of pregnancy would be about the 10th or 15th of July. She was fifty-one inches high, the head small, mind sluggish, and memory defective; yet she was not an imbecile. The clavicles and bones of the upper extremities, though small, presented no special deformities; they did not show the usual rachitic incurvations. The right thorax was very prominent posteriorly and laterally; the left thorax markedly depressed posteriorly and laterally. Both lungs, but more especially the left one, were greatly encreased upon by the deformed thoracical walls. The heart was displaced upward and to the left, its apex being on a level with and external to the left nipple. Pulse 86, of good volume, but intermittent. Bowels moved daily; urination frequent. Urine contained one quarter albumin, and also granular and hyaline tubecasts. The eyelids were slightly edematous, but edema was not recognizable in any other part of the body. The patient complained of frequently recurring frontal headache. At times things seemed darkened to her, and deep spots appeared before the eyes. She had never experienced convulsions, but occasionally had slight fainting attacks.

The vertebral column was markedly curved. The upper third of the dorsal region was slightly convex posteriorly, the lower two thirds markedly convex posteriorly, and also decided convex to the right. The lumbar portion was convex anteriorly and to the left. A left anterior lumbar convexity, compensating for a right posterior convexity of the dorsal region. In the crest position, the lower ribs and the crests of the ilia seemed in contact, and the left iliac crest about one inch higher than the right. Posteriorly there was a deep depression at the sacro-vertebral articulation, and the posterior-superior spines were unduly approximated. Externally examined, the sacrum, in its upper two thirds, seemed directed nearly horizontally backward. External measurements with a pelvimeter showed about fifteen centimetres, or six inches, between the posterior surface of the top of the sacrum and the anterior surface of the top of the symphys pubis. Normally this measurement is about eight inches. Deducting three inches from the external conjugate of six inches would have made the internal or true conjugate three inches. The distance between the anterior-superior spines was measured two and a quarter inches, or ten centimetres, the normal being ten and a quarter inches. Between the widest portion of the crests of the ilia the distance was a little less than that between the anterior-spines—that is, a little less than ten inches, the normal being eleven and one half inches. The measurement between the crests being less than that between the spines, indicated the pelvis to be rachitistic, though it will be seen that the pelvis was not the more usual, typical rachitistic one. The external measurements did not indicate decided transverse narrowing of the true pelvis, though internal manual examination did show decided transverse narrowing. Repeated internal examination showed the promontory to be jagging forward, and the anterior surface of the sacrum to be nearly straight, and directed almost horizontally backward. The symphys pubis was correspondingly inclined downward and backward. The oblique conjugate measured three and one fourth inches, the depth of the symphys pubis one and a half inch; hence, according to Lusk, deducting three fourths of an inch from the oblique conjugate, I estimated the true conjugate to be two and a half inches. The transverse diameter of the superior strait was evidently considerably shortened, but I could not satisfactorily determine the degree of the shortening. The antero-posterior diameter of the excavation was taken to be less than the corresponding diameter of the superior strait, and all the measurements of the outlet less than the corresponding ones of the superior strait. The pelvis was diagnosed to be a generally contracted one, with proportionally greater diminution of the conjugates, and the general contraction increasing from above downward, so as to produce a somewhat funnel-shaped pelvis. The vaginal canal was narrow, the os uteri high up, and the uterine fundus markedly tilted forward. The abdomen was remarkably pendulous.

When the patient first came under our observation, pregnancy seemed to have reached about the end of the ninth lunar month, according to the most probable interpretation of the symptoms, and of the information she gave. The question arose, Would it be best to produce a premature labor at the end of the ninth month, with a generally contracted pelvis, and a true conjugate of two and three quarters inches? I decided that, should a premature labor be attempted under such circumstances, craniotomy, or some other similarly dangerous operation, would be eventually necessitated, and that the dangers of such operation would be increased by the addition of those incident to the production of premature labor. Delivery with forceps, or by podalic version, seemed out of the question. There was a choice between craniotomy, symphysotomy, Cesarean operation gastro-elytrotomy, and the Porro operation. In such a pelvis, craniotomy would have been difficult and tardy, and has been shown, especially by Parry, to be attended with a mortality of mothers too large to compete with abdominal section. I did not prefer the Cesarean operation, because of its excessive mortality to mothers in European hospitals; and because, of the six Cesarean operations performed in hospitals in this country, all were fatal to the mothers. A condition almost essential to recovery after Cesarean operation is rarely met, with, even after normal deliveries, in hospitals. I refer to sufficient retraction of the uterus. A flabby uterus after a Cesarean operation leads to blood poisoning and to general peritonitis. The experience of many hospitals, as also a priori reasoning, would make the Cesarean operation of very questionable justification in hospitals, especially in large maternities, and more decidedly still in general hospitals. The Philadelphia Hospital is not only a general hospital, but is also part of a large almshouse. Gastro-elytrotomy and symphysotomy have given good results in the hands of a few operators, the former especially in America, the latter in Europe; but both operations have been performed with comparative infrequency, and the question of their respective merits cannot be determined by the very limited number thus far performed. I do not desire to discuss in extenso here the general question of the relative value of the different operations performed for the relief of advanced pregnancy in very small pelvises. Among the considerations inducing me to adopt the Porro operation, with Müller's modification, were, the smaller mortality to mothers attending this operation in hospitals, and the opportunity it allows the operator of selecting daylight, and of securing the needed assistants.

The patient was placed under the influence of quinine, of Basham's mixture, and of a mixture of the compound lahaline and of a mixture of the compound lahaline and of a mixture of the compound lahaline. Wooden underwear and proper diet were secured for her. She was isolated from all lying-in women. Her condition did not improve, however, as the time for operation approached; but, on the reverse, a persistent edema of the face, more troublesome headache, and more marked diurnal turberence of vision, with an increasing quantity of albumin in the urine—all pointed to steadily increasing uraemia. The time chosen for the operation was what was supposed to be the end of the thirty-eighth week of pregnancy. A large, well-lighted, well-ventilated room in the Children's Asylum, remote from the obstetric wards, and one that had for years been used as a private parlor, was selected in which to operate, and in which the patient was to remain after the operation. This room was adorned of curtains, carpets, and furniture; its walls and floor were thoroughly scrubbed with carbolic water. The room was then refurnished with chair, table, and a new bed. In short, every means was resorted to improve, as far as possible, the unfavorable conditions incident to so large an institution as the Philadelphia Almshouse.

The members of the obstetric staff had agreed with me in the diagnosis of the patient's deformities, and also as to the propriety of the performance of a Porro-Müller operation. The patient was also kindly examined prior to the operation by Dr. Albert H. Smith, Dr,
Robert P. Harris, Dr. M. O’Hara, and Anna Broomall, M. D. After receiving a full explanation of the nature of the operation, the patient gave her entire consent. The operation was performed on June 30, 1883, with the assistance of Dr. Duer, Dr. Keating, Dr. Musser, Dr. Stryker, Dr. Montgomery, Clara Marshall, M. D., and Dr. Berean, all members of the surgical staff of the hospital, also with the assistance of Dr. McLoughlin, warden of the hospital. There were present Dr. S. D. and Dr. S. W. Gross, Dr. Ellwood Wilson, Dr. J. L. Lulow, Dr. Albert H. Smith, Anna Broomall, M. D., Dr. J. H. Brinton, Hannah Crossdale, M. D., and other physicians.

On the morning of the operation the room was carbolized with the spray, but the latter was not used during the operation. All instruments were kept in a two-per-cent. carbolized solution, and Listerism, minus the spray over the patient, was observed in the different details. On the morning of the operation the patient received a general bath, and the bowels were moved by enema. A half-hour before the operation she received two ounces of whisky. Dr. Joseph Hearn, one of the surgeons of the hospital, and an experienced anesthetist, kindly administered ether during the operation. After etherization the bladder was emptied with the catheter. An incision was then made in the median line of the abdomen seven inches in length, extending from two inches above the symphysis pubis to about one inch above the umbilicus, passing to the left of the umbilicus. The slight bleeding from the lips of the abdominal incision was controlled by artery compressors before opening into the peritoneal cavity. The absence of intestine from in front of the uterus was ascertained by percussion before making the incision. The uterus was easily raised from the abdominal cavity.

Owing to the anterior lumbar curve and to the length of the incision, it was impossible to completely prevent the escape of intestines. After the uterus had been turned out, a protector, made of two layers of flannel, with an intervening layer of protective silk, was placed over the abdomen, the object being to avoid chilling, and to prevent the escape of blood and other fluids into the peritoneal cavity. This protector, when used, was wrong from a warm carbolized solution.

The next step was to place around the cervix the wire of an écaraseur, and to constrict the tissues in its grasp to such an extent as to stop all circulation of blood through the uterus without cutting through the peritoneum. This step required speed, care, and judgment. The liability of a loop of intestine or of omentum to be caught by the constricting wire had to be carefully guarded against. Immediately that sufficient constriction had been secured, a short incision was made with a pointed bistoury through the antero-uterine wall down to the placenta, for the placenta proved to be attached anteriorly. The incision was then rapidly extended, from near the neck to the fundus, with a probe-pointed bistoury, guided by two fingers of the left hand introduced into the incision. The blood pent up in the uterus by the constricting wire escaped freely, but did not enter the abdominal cavity. The incision passed to the external surface of, but not through, the placenta. The hand was immediately introduced into the uterus through the exposed membranes at the fundus, and the child quickly turned out, the placenta being in this manoeuvre detached in main from the uterus. The cord was promptly tied and cut, and the child handed to Dr. Keating. It was asphyxiated when delivered, and presented a very unpromising appearance. It, however, quickly breathed, and cried under the efforts of Dr. Keating at resuscitation. The rapid resuscitation was effected by alternately dipping the child in basins of hot and of cold water. After removing the infant, the uterus, with both ovaries and both tubes, was amputated a half-inch above the constricting wire; this point was about at the internal os. It was then seen that the wire had completely controlled the circulation, and not a drop of blood escaped from the stump of the uterus. The next step consisted in passing oblquely through the stump two steel pins five inches in length, one above the other below the wire. After this a strong carbolized silken cord was passed around the stump, in the line of the wire, and partly tightened. The wire was then cut and removed, and the silk cord then very firmly tightened and securely tied. Special care was given to the tightening of this cord and to the tying of a secure knot. The ends of the pins rested laterally on the abdominal walls, and under the ends, on each side, was placed a piece of sheet-lead. The stump was thus secured outside of the abdominal cavity, and rested at the lower angle of the wound. New carbolized sponges on handles were introduced into the peritoneal cavity, down into Douglas’s pouch, but the entire cavity was free from blood or other fluid. The abdominal wound was then closed by deep and superficial silver sutures. The deep ones were introduced so as to include the peritoneum. During the introduction of the deep sutures, flat carbolized sponges were introduced beneath the incision, so as to catch what oozing might occur from the needle punctures. The external portion of the uterine stump was brushed over with carbolic acid, and then invested with lint saturated with carbolized oil. A strip, two inches wide, of dry carbolized lint was placed on the incision; over this a few strips of rubber adhesive plaster were applied transversely; over these a thick layer of carbolized cotton, and over all a flannel binder. The patient was put to bed, and surrounded with pans of hot water. Dr. Montgomery took charge of the patient’s general condition during the operation, and administered during its performance four hypodermic syringesfuls of whisky. He reports that the time taken up in the operation, from the beginning of the abdominal incision until its complete closure, occupied forty minutes. During the operation the pulse ranged from 100 to 128, the greater frequency being during the making of the incision in the abdominal wall, and was probably due to impeded respiration. The constriction of the cervix had no appreciable effect upon the pulse. Soon after being put to bed, the pulse was 122, but in two hours was 108 per minute, and of good volume. The respirations during the anaesthesia became disturbed and imperfect, producing considerable cyanosis, and probably causing increased frequency of the heart’s action.

The patient rallied well, as was shown by return to consciousness, by bodily warmth, and a fair pulse. For about sixteen hours her condition seemed very favorable, excepting that the kidneys had ceased to act. At the end of twenty-three hours there was marked change for the worse; the mind wandering, pulse 140, temperature 100° F. An inspection of the dressing at that time showed some oozing from the stump—perhaps six ounces—but it had then stopped. An additional ligature was placed around the stump, and one of the uterine arteries was separately ligated; the other could not be found; the stump was also brushed over with Monsel’s solution. There was no subsequent oozing. That there should have been any loss of blood in this manner was a surprise to me, as the original ligature was so very firmly tightened and secured, and had for a number of hours after reaction so perfectly controlled all bleeding. There was marked atresia of the vessels of the stump, as was revealed post mortem. After the twenty-third hour the patient grew progressively worse, became uncontrollable and delirious, had convulsive manifestations, and died in coma. There was no vomiting until twenty-six hours after the operation, and it recurred only once. She experienced but slight pain, and sulphate of morphine was given in small quantity—one fourth of a grain hypodermically; soon after the operation; again, one sixth of a grain at the end of eleven hours—and subsequently about the thirty-sixth hour, because of the great jaundice and the difficulty of keeping the patient in bed. The morphine was given hypodermically by Dr. McLoughlin in such small amount that the coma could not have been due to it. Eight hours after being put to bed the urine was drawn with the catheter. Subsequently the catheter was introduced at different intervals, but on each occasion the bladder was empty, and it was also found empty at the post-mortem examination. Only three ounces of urine were secreted after the operation. The patient survived forty-two hours.

Dr. John Gillespie made a careful analysis and microscopic examination of the urine secreted after the operation, with the following report:

The specimen of urine from the woman upon whom the modified Forro operation was performed, was examined, with the following result: The specific gravity was 1.023; reaction decidedly acid. The urine was of a dirty, yellowish-brown color, and contained a large amount of albumin (much more than one third). The amount of urea contained in the urine received by me was 10.5 grains for the entire amount. Therefore, if only three ounces of urine were excreted in forty-two hours, the total amount of urea excreted would be about fifteen grains. The sediment contained granular, hyaline, and epithelial casts, renal and bladder epithelium, and granular detritus and blood-corpuscles.
Dr. Wile, the acting pathologist of the hospital, conducted the autopsies, and I extract the following from the pathologist's records: On opening abdominal cavity several slight adhesions were found between the visceral and parietal peritoneum in the region of the surgical incision. Blood-vessels around inflenion markedly congested. No exudation or other evidences of general peritonitis. Stomach and intestines distended with gas; spleen small, atrophic. Left kidney: Considerable displacement, found between sixth and seventh ribs. Somewhat lobular, on surface pe-sized cyst, which extends somewhat into the cortical substance of kidney. Cortex reduced, the seat of parenchymatous, solid, interstitial change. Right kidney: Position normal; shape altered, considerable flattening on upper surface; hilus very marked; capsule adherent, seat of parenchymatous change. Both kidneys in state of contraction. Pelvis: One ounce of bloody serum in Douglas's pouch. Peritoneal and subperitoneal tissue the seat of considerable edema. Veins around vagina enlarged. Cervix uteri virginal; orifice round. Liver enlarged; fatty. Thorax: On the left upper anterior side, pleura adherent. Heart: Left side firmly contracted; right relaxed. Right auricle and ventricle seat of a firmly adherent chicken-fat clot. Left ventricle contained small amount of dark, slightly coagulated blood. Left ventricle markedly hypertrophied. Mitral valve, slight thickening. Papillary muscle considerably hypertrophical. Langs: Hypostatic congestion; oedematous. Cause of death: Heart-ecl.

*Report of Histological Appearance of Kidney, by H. Wile, M. D.*

The blood-vessels are for the most part coagulated, filled with corpuscles, and surrounded by a growth of connective tissue. The uriniferous tubules are found filled with cellular and granular debris. Some contain pigment, the result of slight hemorrhages. The epithelium lining of the tubes is granular, and in some places in a state of proliferation, indicating a catarrhal process. The growth of connective tissue between the tubules and about the Malphigian bodies is more marked in some places than in others, and the interstitial process may be regarded as fairly established. A careful measurement was made by Dr. S. D. Lazarus and myself after the pelvis viscera had been removed, with the following result:

**Superior strait:**
- Conjugate: 3 inches.
- Transverse: 4 "
- Right oblique: 3½ "
- Left oblique: 4 "
- Oblique conjugate: 3½ "
- Depth of symphysis: 1½ "
- Obstetrical conjugate: 3½ "

**Excavation:**
- Conjugate: 2½ "
- Transverse: 4 "

Upper four sacral vertebra directed horizontally backward; lower portion of sacrum and coccyx curved sharply forward.

**Inferior strait:**
- Conjugate: 2½ inches.
- Oblique: 3½ "
- Transverse: 3½ "

A perpendicular to the plane of the superior strait is nearly horizontal, striking the abdominal wall about midway between umbilicus and top of symphysis. A perpendicular to the plane of the inferior strait would strike the upper part of the third sacral vertebra.

The death of the dwarf must be attributed chiefly to the existence of interstitial and parenchymatous nephritis. She had rallied from the shock of the operation. There was no peritonitis, excepting in the immediate vicinity of the incision. It was too early for septic poisoning to produce death, and there were no indications that such had occurred. The loss of blood had been trifling, and death occurred too soon to be attributable to exhaustion from this cause. The acute and almost complete suppression of urine, the symptoms after the operation, the symptoms prior to the operation, and the results of examination of the urine and of the kidneys after death, all pointed to the diased kidneys as the cause of the fatal result to the mother. It is well to note that union had occurred throughout the entire extent of the abdominal wound. There were adhesions between the small intestines and the parietal peritoneum along the line of incision. The latter fact is of interest, viewed in the light of death in a few instances after laparotomy being attributed to strangulation of the bowel, due to constriction inflammatory bands. The child was of small size, and died at the end of three weeks, of inanition.

Dr. R. P. Harris remarked that this was the only Porro operation that had been complicated by diseased kidneys. The case was an unfavorable one in consequence of this complication. The albuminous character of the urine was supposed to be due to mechanical interference by the enlarged womb, but, unfortunately, this was not so. The bad habits of the patient had led to a general disease of the arteries as well as of the kidneys. The former were atheromatous. The Porro-Müller operation had been performed thirty-four times; the unmodified Porro, eighty-two times; total, one hundred and sixteen cases, of which forty-eight per cent. had been successful in saving the lives of the mothers. When the pedicle or stump was dropped, it ceased to be a Porro operation. Of thirteen cases in which the stump had been dropped, eleven have been fatal. Dr. Godson was now writing a full history of this operation, including the many experiments which had been made on animals to determine the best method for each step of the operation and the causes of death. Dr. Porro had saved four out of five patients in his own hospitals. In the Milan Hospital nine were saved out of twelve. In Germany the success has been poor, but in Austria better.

Dr. O'Hara asked why the Porro operation should be modified when it had been so successful in the hands of the originator.

Dr. Harris: Dr. Müller was called upon to operate in a case in which the fetus had been dead for some time and was putrid, the uterus being distended with gas. To prevent any septic matter finding its way into the abdominal cavity, he enlarged the abdominal incision, lifted the uterine out of the abdomen, and used cloths around it and over the wound before incising the uterus. This patient recovered. The mortality this year has been very slight.

Dr. E. E. Montgomery had been associated with Dr. Parish in this case, as one of the hospital staff, and at first thought the patient should be allowed to go on to full term before operating, and that Cesarean section or laparo-elytrotonomy, as practiced by Dr. T. G. Thomas, should be the form of operation selected; but Cesarean section had been very fatal in large hospitals, doubtless because it was generally a last resort after the patient has been long hours in labor, and for that reason was dangerous. But, if a large drainage-tube was passed through, entering at the abdominal incision and coming out of the vagina, and a constant flow of antiseptic was kept up, a good condition might be secured. During the operation a few modifications suggested themselves. One of these was to divide the cervix uteri by a V-shaped incision, the peritoneal surfaces being united over the wound, a flat Peaslee drainage-tube being introduced, and the stump dropped. Dr. Harris had told him that Schroeder had tried this, and that it had been done twice by another operator, once successfully. He thought the wire of the cesarean passed around the cervix before removing the child was a source of danger to the latter, besides being likely to embrace a loop of intestine.

Dr. Harris, in criticising the plan of dropping the stump, called attention to the fact that the portion of uterus embraced in the ligature was not a pedicle; it was a stump, and would continue to contract, and oozing of blood, or even profuse hemorhage, was fiable to occur. It had been found impossible to prevent this by any form of ligature that had been tried. If
the stumps was dropped, this hemorrhage or oozing would take place into the abdomen and would be a certain cause of death. Dr. Isaac E. Taylor came near success, but his patient died from thrombosis on the twenty-sixth day, during an attack of phlegmasia alba dolens. It would be very desirable to avoid the dragging on the abdominal wound.

Dr. Montgomery gave a short résumé of the cases treated by dropped stump, and the causes of death in them.

Dr. Parish remarked that the disease of the kidneys was undoubtedly the cause of death, the implanting of the acute condition caused by pregnancy upon the previous chronic disease. He also spoke of the possible deleterious effect of the other upon the system laboring under such a condition of the kidneys. It made the administration of ether in such cases a very serious matter.

Extra-uterine Pregnancy.—Dr. Parish also exhibited specimens from a case of this sort, and made some remarks upon the history of the case. He had attended the patient in her first labor, seven years ago. She was a brunette, of very restless and active habits and disposition, and was quite uncontrollable. She was up and about her house a few days after her labor, and the result was subinvolution, which persisted until her death; during the interval she had passed out of his care and had been subjected to local treatment, including the use of sponge tents. There had developed pelvic inflammation, and afterward she was troubled with frequent micturition and dysmenorrhea. She afterward came under his care again for treatment of these troubles, and on one occasion he had applied leeches to the cervix and given her positive orders not to leave her bed; but festivities were going on, and she went down and assisted in making ice-cream and cake, and also in eating them. This indiscipline was followed by a second metritis. He afterward treated her for the dysmenorrhea by numerous minute punctures of the cervix, the application of tincture of iodoine, and the introduction of a sponge tent. The next period was not so painful, and the second was missed. He told her she was probably pregnant, but two weeks later a slight show occurred, and, fearing an abortion, he advised rest in bed. She refused an examination, and would not be quiet: the flow continued, but did not increase, but there was pain in the pelvis in addition. Eleven days after the flow commenced a sudden attack of intense pain occurred; the patient was completely prostrated, and was carried up stairs. As he was not at home, Dr. O'Hara was called in and used morphine hypodermically. He found, on examination, a mass in the posterior part of the pelvis; the uterus was pushed forward against the pubes. He diagnosed rupture of a Fallopian pregnancy cyst and internal haemorrhage, and gave opiates to relieve the intense pain. The pallor and exhaustion became more pronounced, and death occurred thirty hours after the first symptom. Other physicians who saw the patient did not agree with Dr. Parish in his diagnosis. The autopsy revealed no recent peritonitis; there was blood in the pelvic and abdominal cavities, which had escaped from a ruptured cyst of the Fallopian tube. The foetuses exhibited was found in the pelvic cavity. The position of the cyst was such that it would have been an easy operation to open the abdomen and ligate and remove the cyst, and empty and cleanse the pelvic cavity. The Fallopian tube involved was dilated except at the uterine extremity. The other tube was oculated at the fibratracted extremity; inflammatory bands deranged the relations of the different pelvic organs. We had here the history of inflammatory processes changing the epithelial linings and the relations of the Fallopian tubes to the uterus and ovaries as predisposing causes of extra-uterine pregnancy.

Dr. Harris remarked that the hemorrhage after conception, the peculiar location of the pain, and the pallor, made the diagnosis an easy one. He had had one patient that recovered spontaneously. The operation suggested by Dr. Parish had been performed once successfully. Dr. T. G. Thomas once made the diagnosis and wished to operate, but the husband, a physician, differed in opinion and would not consent; that patient lived sixty hours after the accident. Dr. Playfair in his book advised the operation.

Dr. O'Hara had seen the case early, but could not make such a diagnosis; he saw no sign of internal hemorrhage then. He thought of peritonitis or cellulitis; there had been no history of a cast of the uterus. He did not see how a positive diagnosis of extra-uterine pregnancy could have been made at that time. The patient was certainly going to die, and he would approve of an exploratory operation.

Dr. Parish remarked that Dr. O'Hara was perhaps right. He (Dr. Parish) was the only physician present who looked at the case in that light, all the others disagreeing and giving their reasons. If this diagnosis of a probable extra-uterine perforation had been made early, before the accident, then, when the acute symptoms supervened, a quick diagnosis could have been made as to the cause of the pain. He described a fold of peritoneum found behind the uterus, and, as the clot had the appearance of different ages, portions being yellow, he suggested that an extra-peritoneal hemorrhage had first occurred under this fold, perhaps ten days before the intra-peritoneal hemorrhage which was the cause of death.

W. H. H. Githens, M. D., Secretary.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A stated meeting was held May 12, 1883, Dr. T. M. Mar-ke Chairman.

A Case of Spinal Disease Pursuing a Somewhat Unusual Course.—Dr. Francis Delafield reported a case as follows: The woman was a hospital patient, a girl about twenty years old, a prostitute, who, in April, 1881, gave well-marked symptoms of constitutional syphilis. About the 8th of January, 1882, she had a well-marked hysterical attack, lasting most of the day. Two days later she began to lose power in the legs, first in one and then in the other. By the 8th of February, when she entered the hospital, motor paralysis in both legs was almost complete. There was also well-marked diminution of sensation in the legs, and the bladder and the rectum were paralyzed. It seemed doubtful whether the case was one of hysteria, of transverse myelitis, or one presenting symptoms dependent upon syphilitic poison. Iodide of potassium was administered in large and increasing doses. Improvement took place rapidly, so that on the 16th of February, eight days afterward, she was able to walk about the ward with assistance; the urine could be retained, and sensation returned. The diagnosis was now still more doubtful. The improvement seemed to have been too rapid to indicate syphilitic paraplegia, although it had taken place under antisyphtillic treatment. The patient remained in the hospital until the following October, continuing to take the iodide, and sometimes feeling a little better, sometimes a little worse, but ever able to walk. At that time she considered herself well enough to return to a man with whom she had lived as a mistress, and while there she ceased taking the drug. Loss of power soon returned, and became worse and worse, until on the 31st of December, when she again entered the hospital, paraplegia was complete; she was anemic and emaciated, two bed sores had formed which refused to heal, and her general condition was very deplorable. She died on the 26th of March. There had been no paralysis of the upper extremities.

At the autopsy no lesions were found, except in the spinal
cord and large bed sores. The spinal cord was apparently normal when examined by the unaided eye and by the touch; but the microscope revealed the ordinary lesions of transverse myelitis, beginning in the lower part of the brachial enlargement and extending downward a distance of about two inches. There was no evidence of a gummy tumor. In the light of the post-mortem examination, the case was one of a disease well known not to be amenable to treatment, which, however, did improve for a time, apparently, from the use of the iodide of potassium.

Dr. A. C. Post remarked that an eminent surgeon of this city, deceased, suffered from partial paraplegia and pain in the small of the back, supposed to be due to syphilitic poison, and it was apprehended that it would become worse; but, under the use of the waters of Sharon, improvement took place. The iodide of potassium had failed to give benefit.

**Division of the Meatus Urinarius for the Relief of Locomotor Ataxia.—**Dr. F. N. Otis related the following case, which was suggested by that of Dr. Delafield: Two years ago a gentleman from the country consulted him with regard to incontinence of urine and some loss of motor power in the lower extremities. He was requested to see Dr. Seguin, who gave a somewhat elaborate written opinion of his condition, pronouncing it undoubted locomotor ataxia, and giving a very unfavorable prognosis. He recommended the administration of large and increasing doses of ergot, and, if convenient, a course of treatment by the galvanic cantery. Dr. Otis recognized contraction of the meatus urinarius, and divided it, with the effect of producing almost immediate relief from the urinary symptoms. There was no history of syphilis, but, having recently read an article on locomotor ataxia in which the iodide of potassium was highly recommended in the treatment, he administered the drug, and within a short time the man began to show decided improvement in the motor symptoms, and was at present almost perfectly well, and able to attend to his business as a gentleman farmer. Dr. Otis remarked that he had never failed in such cases to produce benefit by the division of the strictured meatus if it existed.

**Asphyxia from Food entering the Larynx during Etherization; Tracheotomy.—**Dr. H. B. Sands related the following case: Two weeks ago he was performing an operation for necrosis of the tibia in a child five years old while it was under the influence of ether. When he had completed the operation and was about to remove the Esmarch bandage, the gentleman who was administering ether called his attention to the fact that the child was breathing badly. Pulling the jaw forward failed to give relief. The jaws were firmly closed, and it was with difficulty that the tongue was seized with the forceps and pulled forward. Asphyxia became more and more marked, the muscles were all quite relaxed except those of the jaw, breathing had entirely ceased. Dr. Sands hastily, with two incisions, cut into the trachea. Considerable hemorrhage occurred, but the child was turned on its face, the tips of the fingers were inserted into the incision made and the edges separated, and slight respiration took place. In a moment the crisis was over, the child breathed pretty well, and he was able to insert a tube. Through the tube a considerable quantity of boiled egg found exit, and afterward two pieces of meat, each about half an inch in diameter, and supposed to have been ejected from the mouth, were found upon the pillow. The tube was removed the next day, and the child had done perfectly well since. Instructions had been given not to allow the child to have any solid food after 8 A. M. The operation was done at 2 P. M. It occurred to him now that a longer interval should exist between the taking of food and the performance of the operation. This was the first time that the accident had happened in his experience. It was evidently due to asphyxia, and not to the influence of the anesthetic upon the heart. The face was livid, not pale, and attempts were made at respiration, but without effect. He supposed that in such a case the heart would have been found beating, and that life would have lasted for a number of minutes after respiration had ceased. Dr. Briddon had shown to the Pathological Society a number of years ago the larynx of a child that had died in the dentist's chair, and it was said that death did not occur until quite a number of minutes after the bad symptoms were noticed, but the nature of the symptoms was not understood, and the child died asphyxiated. At the autopsy a piece of liver was found in the interval between the vocal cords, completely obstructing the larynx.

Dr. Post asked if it was not unlikely that food would remain in the stomach so long a time as in the case just narrated without being digested.

Dr. Sands said that in the adult the anxiety regarding the operation not infrequently delayed digestion for some hours.

Dr. Delafield and Dr. Walker remarked that they had observed curdled milk on using the stomach pump more than three hours after the milk had been taken.

**Bronchial Hemorrhage with Unusual Symptoms.—**Dr. W. McCready said that, on the 25th of April, 1883, he was sent for in great haste to see a woman who was said to have hemorrhage from the lungs. On his arrival, ten minutes afterward, he found a woman, seventy years of age, previously in good health, who had been spitting blood, whose pulse was very rapid and feeble, the respiration frequent, the face pale. Nothing abnormal could be detected over the right side of the chest. Over the left side there were no signs of breathing; it was perfectly flat on percussion from summit to base. The same signs were found anteriorly and posteriorly. The heart was not displaced; the intercostal spaces were depressed as usual. There were no signs of pleurisy or any effusion. Dr. Delafield saw the patient with him the next day and confirmed the foregoing statement, but he believed there must have been fluid in the chest, although the only sign thereof was flatness. Two mornings later he was again summoned to the patient, who had again been spitting blood. The nurse showed him a number of blood-clots, one of which, on examination by Dr. Delafield, proved to be a cast of a bronchus and several of its terminal ramifications. The circumference was formed of laminated fibrin of a yellowish color, and in the center was loosely coagulated blood. Upon examining the patient again, the lung upon the left side was found more resonant; air entered it imperfectly. The pulse was still frequent, and the patient felt much depressed. She continued to spit a few small clots of blood for a day or two; but strength gradually returned, the cough disappeared, the pulse had become normal, breathing was re-established in the left lung—although it was not yet vesicular in the lower portion—and she expressed herself as being comfortable.

Dr. Delafield remarked that the blood which was coughed up after that which formed a cast of the large bronchi consisted of casts of small bronchi. There was no membrane surrounding the large clot which would indicate any inflammatory process. It was not unusual for hemorrhage to take place from a bronchus, from the mucous membrane, from small cavities, or from an aneurysm; but, as a rule, in such cases most of the blood was coughed up, or, if not, it entered the smaller bronchi and the air vesicles; it did not remain in the larger bronchi and form a firm clot, to be expectorated in that form. Should a clot form within the larger bronchi and occlude its lumen, air could not, as a matter of course, enter the lung; but how complete flatness on percussion could be produced thereby he could not understand. As soon as the cast of the large bronchi had been coughed up, flatness and dullness began immediately to disappear.
Reports on the Progress of Medicine.

GENERAL MEDICINE.

BY ALEXANDER DUANE, M.D.

The Relation of Micro-organisms to Tuberculosis.—Dr. W. W. Cheyne's report ("Practitioner," April, 1883) is a valuable contribution to our knowledge of the nature of tuberculosis and its bacillary origin. The first part of the paper is taken up with an interesting description of the author's visit to the laboratories of Toussaint, Schüller, and Koch, and of his own observations of their methods of work. He was evidently impressed with the superiority, both in point of accuracy and thoroughness, of the researches carried on by Koch. By the latter, as well as by Toussaint, he was given specimens of their work which he brought home, and upon which he made numerous experiments, the results of which are detailed. All his experiments, which are numerous and appear to be well conducted, point to one conclusion, viz.: The micrococci, which Toussaint described as the cause of tuberculosis, were absent from the tissues of tuberculous animals obtained from his own laboratory, when these tissues were examined with proper precautions, and, further, the injection of cultivated micrococi obtained from his laboratory failed in every case to produce tuberculosis; on the other hand, tuberculous material, whether obtained from Toussaint's or Koch's laboratory, universally contained Koch's bacilli, and the injection of these bacilli, and of their cultivations, produced tuberculosis in previously sound animals. Among the specimens examined were a number of human tuberculous and serofibrous organs and tissues (phthisis with excavation, fibroid phthisis, strumous articulare disease, serofibrous lymphatic glands, tuberculous kidneys, testicles, etc.). In these the number of bacilli present appeared to bear a relation to the intensity of the morbid process, the greatest number being found in cases of acute miliary tuberculosis, while in cases of fibroid phthisis which had become stationary the bacilli had disappeared or were very few. The conclusion which Cheyne draws from these observations is that pulmonary phthisis, whether acute or chronic, is always caused by the inhalation of bacilli, which arrive in the alveolar epithelium, there lodge, proliferate, cause surrounding destructive changes, and so extend to other alveoli. If the surrounding reactive inflammation is intense, and the growth of the bacilli rapid, excavation and excavation take place; if the contrary is the case, connective-tissue formation occurs about the focus of irritation, and we find the changes of fibroid phthisis. *

While lodged in the alveolar epithelium, the bacilli are not in direct relation with the blood-vessels, and hence can not have access to the circulation; when, by wandering from their place, they do penetrate the vascular walls and enter the circulation, the phenomena of general tuberculosis are developed. An interesting example of this is furnished by one of the specimens from Koch's laboratory.

To the objection which has been raised against the specific character of tuberculosis, that the inoculation of non-tuberculous material will produce the disease in rabbits and similar animals, Cheyne declares that this never takes place if proper antiseptic precautions are taken at the time of introduction of the foreign bodies. He himself has introduced the most varied forms of irritants (altogether in nearly a hundred cases), without in a single instance inducing tubercular lesions. Occasionally, single cheesy nodules resembling tubercles were observed, but these, on microscopic examination, turned out to be simple inflammatory foci, in most cases dependent upon the presence of parasites.

For details as to methods of work, and reports of the different cases, we would refer the reader to the original, which he will find well worth his perusal.

Acute Circumscribed Cutaneous Edema is the name given by Quincke ("Edinburgh Medical Journal," June, 1883) to a diseased condition in which oedematous tumefactions, circumscribed in character and appearing and disappearing quite suddenly, develop in the loose subcutaneous tissue in different parts of the body, but especially upon the extremities about the joints and upon the face about the lips and eyelids. They may also appear upon the mucous surfaces. These tumefactions are not inflammatory in character, give no pain, and seldom itch. One attack lasts from a few hours to a few days, but may be protracted by the occurrence of successive relapses. The affection once established is liable to recur. Jamieson, in his paper upon the subject, gives an account of one case which he has observed, with reminiscences of similar cases which probably might be brought under the same category. Similar cases have also been described by Milton, Landon, Duhring, and Kemper. Jamieson relates a case in which pulmonary edema suddenly developed and as suddenly disappeared in a healthy woman, and believes that this case is an illustration of a variety of morbid action similar to that which obtains in the malady described by Quincke. He believes that all such cases should be referred to a neurotic source, and thinks that an outbreak such as they represent is really a "nerve-storm," an explosion of nerve-force due to a periodically recurring instability of equilibrium in the nervous system."

The Causes of Convulsions in Children.—Kjellberg, in an interesting article on convulsions in children ("Archiv. für Kinderheilkunde," iv., 1883), classifies the former into symptomatic and sympathetic. Symptomatic convulsions are due to direct irritation of the "convulsion center" in the medulla oblongata, and may be brought about either by changes in the amount of blood supplied to the brain or by alterations in the quality of the blood. Changes of the former kind occur as the result of anæmia (which to produce convulsions must be sudden in its development), active (dilatary) hyperæmia, and passive
(venous) hyperemia. Anemia of the brain, again, may in children be due to sudden hemorrhage, to excessive loss of fluid in diarrhea or vomiting, to arterial spasm, to compression of the skull from without, to intracranial pressure from external changes in the brain itself, and to the effect of certain general diseases. Active hyperemia, which, as the author points out, really produces cortical anemia by constriction of the cerebral capillaries due to the reactionary pressure exerted upon them by the circulating blood-fluid, occurs very frequently in children, and is brought on by anything which will increase the heart-action—emotion, the febrile state, etc. Passive hyperemia of the brain occurs in children as the result of laryngeal or intra-thoracic obstruction to the entrance of air, or of cardiac disease or of distention of the stomach exciting both respiratory and cardiac embarrassment. Changes in the character of the blood supplied to the brain, constituting the second class of causes producing convulsions by direct irritation of the medulla, are themselves induced either by pyrexia, by the introduction of toxic substances (atropine, tobacco, alcohol, poisonous gases) from without, or by the development of poisons within the circulation (pyrexia, cholera, etc.). Whether the uremic poison acts directly upon the medulla, or indirectly by its effect in causing cerebral anemia, is uncertain. The second great division of causes which may produce convulsions includes all agents acting upon the peripheral nerves and producing spasm by reflex irritation (sympathetic convulsions). Such causes are found in irritation due to wounds, burns, and other lesions of the integument, foreign bodies in the ear and nose, renal calculi, etc. By far the most frequent seat of irritation, however, is found in the alimentary tract. Among other causes included under this latter head the author considers to which great importance is attached, namely, teething and the presence of worms in the intestines. Both, he thinks, have their influence, which, if they were to be denied absolutely, as some have done, but this influence is certainly pretty limited, and he especially warns us against ascribing every attack of convulsions in children who have worms to the account of the latter. The author believes that a hereditary predisposition exists in some cases to account for the convulsions. In other cases convulsions are simulated, and the detection of the imposture may be quite difficult. It is worthy of remark that Jellberg, in giving a reason for the prevalence of convulsions in childhood, ascribes it not to an excessive excitability of the nervous centers, but to a deficient activity of the cerebral centers which inhibit reflex activity.

Diphtheritis nephtitis.—Fürbringer's paper ("Archiv für pathologische Anatomie und Physiologie und für klinische Medicin," xei, 3) consists in an analysis of the urinary symptoms and the results of the post-mortem examination in ten fatal cases of diphtheria, together with a comparison of his results with those of other investigators. The pathological changes occurring in diphtheritic nephritis are, according to some, a hyperemic and hemorrhagic condition of the kidney with extensive tubal and interstitial changes (Oertel); according to others, extensive fatty degeneration evidenced macroscopically by the presence of a large yellow or yellowish-white kidney (Weiger); while, according to a third party, the renal changes in diphtheria are found principally in the tubes of the cortex, the glomeruli and interstitial tissue being little involved, and the organ itself slightly enlarged, rather soft and nearly anemic (Wagner). From his own examinations, Fürbringer believes that the hyperemic forms described by some are only the results of renal congestion, and that the essential lesions referable to the diphtheritic process are to be classified under three heads, representing as many different stages of the inflammatory process. These are as follows: 1. Gross appearance of kidney normal, cortex anemic. Parenchymatous degeneration of cortical epi-

thelium. This form resembles closely the form of renal lesion found in pyretic conditions. 2. Cortex slightly enlarged and anemic: cut surface rather granular: extensive degeneration of the cortical and glomerular epithelium; beginning interstitial changes; no vascular lesions. 3. Large yellow kidney, with extensive fatty degeneration and advanced alterations of interstitial tissue; a form resembling that found in scarlet fever. In no instance among the author's cases has he found micrococci in the kidney, at least in quantity sufficient to convict them of producing the renal lesions by their direct local influence. Fürbringer, accordingly, while acknowledging the power of the micrococci as carriers of the diphtheritic contagium, and as the indirect source of all the lesions of the disease, does not believe that they can exert any immediate mechanical or chemical effect upon the renal tissues. He seems to have used a good deal of care in reaching this result, to secure it from the suspicion which naturally rests upon all purely negative determinations. In the urine also, while casts, renal epithelium, and leucocytes were constantly present, micrococci were universally absent. The characteristic symptoms of renal involvement in diphtheria, as judged from his cases, were a diminution in the amount of urine so great as not to be explained either on the ground of simple renal congestion or of the pyrexia, and not associated with a high specific gravity or a deep color, and albuminuria varying in degree with the intensity of the general symptoms; with these were joined the negative symptoms of absence of edema and of cardiac hypertrophy.

Cardiac Thrombosis in Acute Diseases.—Goodridge ("Practitioner," June, 1888) believes, in common with some of the more recent writers, that cardiac thrombosis may act as a cause of death in acute disease, and not occur merely as a pro-
erogenic phenomenon. He bases this opinion upon the history of three cases in which death occurred with a greater or less degree of suddenness, and with attendant symptoms of dyspnea, thoracic oppression, rapidly diminished heart-power, and a sense of impending dissolution. In these cases there were found, post mortem, firm, decolorized fibrous cagulum, occupying, in one case, the left ventricle and the beginning of the aorta, in another case extending from the right ventricle into the pulmonary artery, and in the last case blocking the right aorta and the superior vena cava. In the latter case the fibrous cagulum was distinctly laminated in structure, and the character of the symptoms pointed to a progressively increasing interference with the function of the right heart.

Miscellany.

Therapeutic Notes.—The Therapeutic Use of Chloroform-Water.—M. Pierre Vigier calls attention ("Gazette hebdomadaire de médecine et de chirurgie," August 31, 1883) to the therapeutic value of eau chloroformée. This preparation is much more stable than chloroform itself. Chloroform, chemically pure, if submitted to the action of the sun, is decomposed, with the production of chlor-carbonic gas, in forty days, while chloroform saturated with water resists decomposition a hundred days, and chloroform water, placed under the same conditions, remains absolutely in a state of purity. Physicians can, then, rely on the purity of this new medicament. To prepare chloroform-water, add pure chloroform in excess to a flask three quarters full of distilled water, shake the mixture from time to time for an hour and allow the excess of chloroform to settle until the liquid above is perfectly clear. The two are then separated by decantation. The mixture contains 0.90 grammes of water to 1.00 grammes of chloroform. When

* Soumis à l'insolation directe ou diffuse.
The success of the treatment, Dr. Gibbes states, is largely, if not wholly, a question of attention to minute details.

The Medicinal Value of the Salts of Nickel.—Professor J. M. Da Costa, of the Jefferson Medical College, Philadelphia, concludes in a "preliminary paper" ("Medical News," September 29, 1883), after a year's experimentation, that "the preparations of nickel, especially the bromide, will be found additions to our therapeutic resources, and are certainly worthy of more careful study than they have hitherto received."

Investigations were made with the chloride, acetate, phosphate, sulphate, and bromide. The sulphate and the bromide proved to be the best preparations. The sulphate used was made by digesting nickel filings in dilute sulphuric acid and evaporating. The salt is chrome-green in color, very deliquescent, and very soluble in water. It was given in solution or in pill, in from one-to-three-grain doses. Small doses were well borne by the stomach. Five grains sometimes caused giddiness and nausea. There was little action on the pulse or temperature; if anything, they were slightly reduced. The salt was somewhat sedative and antodyne, but not directly soporific in its properties. There was little evidence of its reputed tonic effect. In obstinate diarrhoea excellent results were obtained from small, frequently repeated doses, or from one-to-two-grain doses given four times daily. In one such case, associated with valvular disease of the heart and with the trembling of beginning sclerosis, it was successful after many remedies had failed. It subsequently benefited the heart trouble, but not the nervous affection. In chronic constipation of the stomach the sulphate acted well and the chloride even better. "In the case of a professional man with marked indigestion and some albumin in the urine, in whom iron produced headache and otherwise disagreed, the digestive disorder was speedily influenced and the albumin disappeared while taking one grain of the chloride three times daily. More than this did not agree."

Bromide of nickel, a green, deliquescent, very soluble salt, was obtained by digesting nickel filings in bromine and water, and evaporating carefully to crystallization. It acted similarly to the other bromides, but much smaller doses would suffice. Five to seven and a half grains proved an average dose; ten, a decided one. If ten grains ever disappeared, one half the quantity was given, and soon repeated. Bromide of nickel was found to allay headache, especially of the congestive form, to relieve convulsive movements, and to act as a general sedative to the nervous system. In epilepsy it was found in all cases to act quite as well as any bromide, "and, as happens with all, we sometimes by a change to it obtain results which the others no longer yield."

From the "Illustrative" cases detailed, it would seem that in intractable epilepsy, in one instance, when the other bromides and several other remedies were ineffectual, the bromide of nickel, in from five-to ten-grain doses, was markedly beneficial, especially at first. The drug appears to lower the temperature slightly, and, possibly, to reduce the frequency of the pulse a trifle. It does not act on the skin or bowels, or on the composition of the urine, the quantity of which may be unchanged or slightly increased. The results from a dose smaller than that of the bromides generally used are striking. Nor can they be accounted for by the presence of a greater percentage of bromine. The combining weight of nickel is between the combining weight of sodium and that of potassium, the three being, respectively: sodium, 23.3; nickel, 29.9; potassium, 39.2. There must be, therefore, some special action in the bromide of nickel.

The sulphate and chloride of nickel diminished somewhat the number of the epileptic attacks, but, while they were not inert, their controlling action is slight compared with that of the bromide.

Bromide of nickel was given in solution or in pill form, made with gum tragacanth. The preparations used were made with great care by a skilled pharmacist, Mr. McKelway, and were chemically pure.

Serpent-Venom as a Remedy for Tetanus.—A. O. Ameden, M.D., of Glens Falls, N. Y. ("Medical News," September 29, 1883), reports the successful treatment by serpent-venom of a severe case of tetanus which refused to yield to other remedies. The patient was a healthy boy about twenty-five years old. A punctured wound of the foot was followed in three days by tetanic symptoms, which rapidly assumed an most aggravated form. Chloroform, chloral, and bromide of potas-
sian were freely used without benefit. The marked contrast in the symptoms and condition caused by tetanus and by snake poisoning led to the conclusion that the two poisons, so to speak, ought to counteract each other. The point of a hypodermic needle was moistened with fresh venom from a rattlesnake (the case occurred in a region infested with rattlesnakes), and the needle thus "medicated" was inserted into the cellular tissue in the upper dorsal region near the spine. Symptoms of snake poisoning came on rapidly, with marked amelioration of the tetanic spasms and rigidity. They entirely ceased in ten hours, and the patient enjoyed six hours' quiet sleep. Thirty hours after the poison was inserted, slight spasms and rigidity returned. The previous procedure was repeated. The tetanus gave no further trouble, and a fairly rapid recovery followed. However, the second introduction of the venom, Dr. Ameden believes, might have been withheld. It caused extreme prostration, and rendered active alcoholic stimulation necessary. Otherwise, the results were all that could be desired. There was no diffuse inflammation in the wounds, or any other unpleasant consequence. Dr. Ameden is of the opinion that snake-venom, or "crotalino," may be used with comparative safety, and may prove a valuable remedy in tetanus and, possibly, in some other spasmodic diseases.

The New York Post-Graduate Medical School.—The order of the clinics and courses for the regular term of 1882-1883 is as follows:

10 to 11 A.M.—Diseases of Children: Dr. McNutt, Mondays and Wednesdays; Dr. Jacobi, Tuesdays and Fridays; Dr. S. M. Roberts, Thursdays and Saturdays.

11 A.M. to 12 M.—Clinical Medicine: Dr. Porter, Mondays and Saturdays; Dr. Burt, Tuesdays and Thursdays. Clinical Gynecology: Dr. Skene, Wednesdays. Surgical Dressings: Dr. Powell, Fridays. Obstetrics: Dr. Partridge, Tuesdays and Saturdays.

12 M. to 1 P.M.—Clinical Surgery: Dr. Little, Mondays, Wednesdays, and Fridays. Orthopedic Surgery: Dr. M. J. Roberts, Tuesdays, Thursdays, and Saturdays.

3 to 4 P.M.—Clinical Gynecology: Dr. Dawson, Mondays, Wednesdays, and Fridays. Diseases of the Eye and Ear: Dr. Moore, Tuesdays, Thursdays, and Saturdays (at the New York Eye and Ear Infirmary).

At 2.30 P.M.—Diseases of the Throat and Nose (hospital clinics): Dr. Whiting, Mondays, Wednesdays, and Fridays; Dr. Wagner, Tuesdays, Thursdays (at the Metropolitan Throat Hospital). Diseases of the Eye and Ear: Dr. Roosa, Tuesdays, Thursdays, and Saturdays (at the Manhattan Eye and Ear Hospital). Normal and Pathological Histology (laboratory): Mondays, Wednesdays, and Fridays.

3 to 4 P.M.—Skin Diseases: Dr. Sturgis, Mondays, Wednesdays, and Fridays.

4 to 5 P.M.—Diseases of the Mind and Nervous System: Dr. G. M. Hammond, Mondays; Dr. Dana, Tuesdays and Thursdays; Dr. W. A. Hammond, Wednesdays, Fridays, and Saturdays. Diseases of the Eye and Ear: Dr. Moore, Mondays, Wednesdays, and Fridays.

5 to 6 P.M.—Pathology and Clinical Medicine: Dr. Satterthwaite, Mondays, Wednesdays, and Fridays; Dr. Smith, Tuesdays and Thursdays.

7 to 8 P.M.—Veneræal Diseases: Dr. Littie, Tuesdays and Thursdays.

8 to 9 P.M.—Anatomy and Physiology of the Nervous System: Dr. Spitzka, Wednesdays and Fridays.

Courses in operative surgery and in ophthalmoscopy will be held in the evening.

Clinical Lectures on Diseases of the Skin.—Dr. Bulkley's seventh free course at the New York Hospital began on Wednesday, the 17th inst., and will continue every Wednesday, at 2.30 p.m., until twenty lectures have been given.

Abscesses of the Neck which may cause sudden death.—The late Dr. John A. Liddell ("American Journal of the Medical Sciences," October, 1883) points out that sudden death may occur from deep-seated abscesses of the neck, or the continuance of life may be greatly endangered, much oftener than is generally supposed, and that these abscesses in the neck are more frequently attended with hemorrhages due to the opening of important blood-vessels by ulceration or erosion, and by ramollissement consequent upon the disorders themselves, than abscesses in the other surgical regions. The superior liability of cervical abscesses to the spontaneous occurrence of dangerous hemorrhages arises in part from the greater number and importance of the cervical blood-vessels; but more particularly from the inanition and exhaustion, or low state of the constitutional powers, and consequent feebleness of the reparative forces, which rapidly result from most of the deep abscesses of the neck, or, rather, from the inability to swallow enough food to support life, and from the powerlessness to get any refreshing sleep, or even repose, with which these abscesses are sometimes attended. The septic or toxic influence of the fatal secretions and exudations which present themselves in the oral and fascial cavities in many instances also aids materially to still further depress the patient and weaken the reparative processes of his system. These deep-seated abscesses of the neck, when allowed to run their own course, do not exhibit any tendency to a spontaneous cure; but, on the contrary, they always tend to destroy life by burning or spreading, etc.; and Dr. Liddell shows that the earlier they are laid open and evacuated the better for both patient and surgeon.

Army Intelligence.—Official List of Changes of Officers serving in the Medical Department of the United States Army from October 6, 1883, to October 15, 1883.—Hammond, John F., Colonel and Surgeon. Leave of absence on surgeon's certificate of disability, granted April 2, 1883, extended six months on surgeon's certificate of disability. Par. 7, S. O. 281, A. G. O., October 8, 1883. ——— Swift, Ebenezer, Lieutenant-Colonel and Assistant Medical Purveyor, under the provisions of section 1 of the act of Congress, approved June 30, 1882, is, by operation of law, this day retired from active service, and will proceed to his home. Par. 4, S. O. 281, A. G. O., October 5, 1883. ——— Hartley, Albert, Major and Surgeon. Granted leave of absence for fifteen days: Par. 2, S. O. 305, Department of the Missouri, October 6, 1883. ——— Meacham, Frank, Major and Surgeon. Assigned to duty at Fort Douglas, Utah. Par. 3, S. Naval Intelligence.—Official List of Changes in the Medical Corps of the Navy during the week ending October 19, 1883.—Surgeon Thomas Hillard, granted leave of absence for one year, with permission to leave the United States Surgeon William J. Simon and Passed Assistant Surgeon M. H. Crawford, ordered to report on November 1st for duty on board the United States steamer Trenton.

Society Meetings for the Coming Week.—Monday, October 22d: Medical Society of the County of New York (annual). Tuesday, October 23d: New York Academy of Medicine (council); New York Surgical Society; New York Dermatological Society (private); Medical Society of the County of Putnam, N. Y.; Jersey City Pathological Society. Wednesday, October 24th: New York Pathological Society; American Microscopical Society of the City of New York; American Association for the Cure of Inebriates (New York); Philadelphia County Medical Society. Thursday, October 25th: New York Academy of Medicine (section in Obstetrics); Harlem Medical Association (private); Brooklyn Pathological Society. Friday, October 26th: New York Clinical Society (private); New York Society of German Physicians (private); Yorkville Medical Association (private). Saturday, October 27th: New York Medical and Surgical Society (private).
LECTURES AND ADDRESSES.

A REVIEW LECTURE ON MAGNETISM AND ELECTRICITY,
DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS,
BY CHARLES F. CHANDLER, Ph. D.,
PROFESSOR OF CHEMISTRY AND MEDICAL PRESCRIPTION.

Magnetism.

Gentlemen: I will say only a word about magnetism. A magnet is either natural or artificial. A natural magnet is a piece of magnetic iron-ore or magnetic oxide of iron (Fe₂O₃), also called lodestone, and it occurs in nature. An artificial magnet is one produced by artificial means. Artificial magnets are of two kinds—permanent and temporary. A permanent magnet is a piece of steel that has been magnetized by bringing it in contact with another magnet or piece of lodestone, or by passing a strong current of electricity around it. A temporary magnet is a piece of soft iron which has been made temporarily magnetic by being brought near to a permanent magnet, or by passing a current of electricity through a coil of wire surrounding it. The properties of a magnet are: 1. The power of attracting certain metals—iron, nickel, cobalt, and, to a slight degree, chromium, and a few others. 2. The property of tending to assume a certain position as regards north and south. A magnetic bar or needle, if allowed to hang by its center on a string, or to float free on a piece of wood in water, will assume a position approximating north and south, but not exactly so. 3. The property of polarity—that is to say, a magnet exhibits its peculiar attracting powers chiefly at the extremities. There is a center of attracting power near each end, but not absolutely at the end, and at this point or center the magnetic power is strongest. These two magnetic centers are called the poles of the magnet; the end which points toward the north is called the north pole, and the one pointing toward the south the south pole of the magnet. When two magnets are brought near each other, the north pole of one will attract the south pole of the other, and repel the north pole. So it has been found to be a law with magnets that “like poles repel, and unlike poles attract each other.” With regard to the direction the magnetic needle takes when allowed to move freely, it does not point directly north and south, but it assumes a position pointing a little to the east or to the west of north and south, depending upon the locality at which the observation is made. This is because the magnetic poles in different parts of the earth do not correspond exactly with the geographical poles, and the difference between them varies with the location at which the observation is made. This is why nautical almanacs are made to tell mariners the amount of variation from the true north and south made by the compass-needle in different parts of the world. This deviation of the compass-needle from the true north and south is called the “declination” of the needle. The term “declination” is very liable to be confounded with that of “inclination.” When a bar of steel is hung by a thread at its center it assumes an exactly horizontal position; but, if this bar of steel is now magnetized, it will assume a direction pointing north and south, but it will no longer hang exactly horizontal except at the equator of the earth. At all points north of the equator the north pole of the bar will dip downward, and the farther north you get the greater will be the dip, while at all points south of the equator the south pole of the bar will dip downward: and the degree to which the needle dips from the absolutely horizontal direction is called its “inclination.” This is because the two magnetic poles of the earth do not correspond to the two geographical poles, but they appear to lie nearer the center of the earth. To overcome this tendency of the magnetic needle to dip at a varying angle according to the distance north or south of the equator, the needle of the mariner’s compass is made by uniting two magnetic bars laid parallel, with the north pole of one adjacent to the south pole of the other, so that they lie with their opposite poles end to end. Such a needle is said to be “static.” At a point on the surface of the earth corresponding with latitude 75° N. and longitude 96° 43’ W. the north magnetic pole seems to be located, and at this place the dipping needle assumes a vertical direction. The south magnetic pole is apparently located at latitude 75° 5’ S. and longitude 154° E.

The production of magnetism by induction is a curious phenomenon. If a permanent magnet is brought near a handful of iron nails it will attract them to it, and as soon as a nail becomes attached to the magnet it becomes a magnet itself and attracts another nail, which in turn becomes a magnet and attracts another, and so on, the magnetic power of each new nail attracted becoming constantly less than that of the preceding one. It is not even necessary that the nail should absolutely touch the magnet in order to assume this magnetic power, for it will be transmitted through short spaces from one to the other. This power which a body acquires by being brought near a magnet is called “magnetic induction.” An important fact in this connection is that when a coil of iron wire is made to surround a permanent magnet it becomes magnetic itself by induction, and is capable of inducing magnetism in another bar of iron surrounded by it. This principle is made practical use of in the construction of the telephone and magnetic telegraph.

Electricity.

We now come to the subject of electricity. This is a peculiar agent, capable of producing certain astonishing results. There are different forms of electricity and different ways of generating it. The different forms are statical electricity, dynamical electricity, and magnetical electricity, or magnetism. It may be generated by means of friction, percussion, heat, chemical action, elavage, and by magnets. The effects of electricity in its different forms are manifested as attraction, repulsion, light, heat, violent commotions, and chemical decomposition.

To excite electricity we must always do something, and the first way of producing it, discovered in the earlier ages, was by rubbing amber, and so the term electricity was derived from the Greek word ἕλεκτρον, signifying amber.
It was afterward found that certain other substances when rubbed assumed electrical properties, and would attract or repel other materials. This electricity produced by rubbing or friction is called statical electricity. This is a form of electricity that can be held for a considerable length of time, and hence it has received the name of stationary or statical electricity. This is the only form of electricity that we can store up and keep for a time. What is known now as the storage battery does not really store up electricity, but only energy, which can be transformed into electricity at will. So much for statical electricity.

We have a totally different kind of electricity, called dynamical electricity, or electricity in motion. This is a form of electricity that circulates only in a conductor or along a wire, and it can not be held. It was first discovered by Galvani in experimenting on frogs' legs, and hence it is often called galvanic electricity. It is now ordinarily produced by means of galvanic batteries and dynamo-machines. The third form of electricity we have already referred to incidentally as that which is induced by means of magnets, and it is therefore called magnetic electricity, or magnetism.

According to the generally accepted theory, there are two so-called electrical fluids, and these two are commingled in equal proportions in all bodies; and hence all the processes for getting electricity must result in pulling these two electrical fluids apart, and in taking a portion of one away from a body. These two fluids are called, one positive, and the other negative electricity. It is found that when two bodies are electrified with the same kind of electricity, as both with positive, or both with negative, they repel each other; but when the two bodies are charged with opposite kinds of electricity, as one with positive and the other with negative, or when one body is charged with either kind while the other is left in its normal condition, then the two bodies attract each other. Hence we derive the law which states that “bodies charged with like forms of electricity repel, and those with unlike attract.” The gold-leaf and pitch-ball electroscopes are constructed on this principle.

When a piece of sealing-wax is rubbed, it manifests electrical properties for some time, but certain other substances, like metals, for instance, after being rubbed in the same manner, show no electrical properties, and this is because the electricity easily gets away from them. Thus we find that while certain substances remain electrified for some time others do not, and hence these bodies are named conductors and non-conductors. But these terms are not absolute, but only comparative. The metals, carbon, gypsum, and acids are called good conductors, while amber, glass, sulphur, and silk are poor conductors. If we want to insulate electricity and keep it from running off into surrounding objects, we surround the object containing it with a poor conductor. Thus the glass insulators on telegraph poles prevent the electricity from leaving the wires and running off into the ground, and the non-conducting materials placed around the wires of the Atlantic cable so protect it that a small charge of electricity will carry a message from here to Europe.

Great difficulty is experienced in experimenting with statical electricity because it so easily gets away. All substances are conductors to a greater or less degree, including the dust in the air and the moisture in the atmosphere. Perfect insulation and a warm, dry air are, therefore, favorable conditions for holding statical electricity. The reason it was not used earlier for practical purposes was because it was so difficult to manage. The electricity which is produced on glass by friction is called vitreous or positive, while that produced in the same manner on sealing-wax is called resinous or negative electricity. Franklin had a theory that there was but one electrical fluid, and that all substances in the natural state had an equal amount of it, but a body charged with an excess of this fluid was said to be in a positive state, and one in which there was a deficiency was said to be in the negative state. But this theory has now given place to the two-fluid one, which maintains that all bodies are charged with an equal amount of the two electrical fluids called positive and negative, but when a body is electrified these two fluids are separated so that one remains in excess of the other. There is always a passage of the electrical fluid in two directions along a conductor, but, when the direction of the current is spoken of, it is the direction of the positive current that is always meant. Statical electricity can also be produced by pressure, as when certain crystals are firmly pressed together; by cleavage, as when two layers of mica are split apart; and by heat as well as by friction. It may also be produced by torsion. It is found that the charge of electricity if collected in a spherical body is on the outside, and not within the body, and if it is not a spherical body the electricity collects chiefly at the part most nearly pointed. This kind of electricity is transferred in three different ways: 1. By conduction from one body to another in contact with it; 2, by convection, where gas or the air in contact with an electrical body takes away some of its electricity; 3, by discharge, where a highly electrified body suddenly loses a portion of its charge.

Machines for producing statical electricity are usually based on the friction method. The old-fashioned machine consisted of a circular glass plate which was rotated between two cushions, and the electricity thus produced was taken off and carried to a metallic cylinder, called the prime conductor, by means of metal points. Silk and glass as insulators prevented the electricity from running off into neighboring objects. More recently machines have been constructed on the principle of induction, as illustrated in the electrophorus. These are known as the Holtz machines.

The condensation of electricity is illustrated in the Leyden jar. This is a sort of bottle, lined up to a short distance from its top, both inside and outside, by tin-foil, and in the stopper is a brass knob which is connected with the tin-foil on the inside of the jar by a chain. When the knob is charged with positive electricity from a machine, it collects on the tin-foil inside the jar, while a corresponding amount of negative electricity collects on the outside of the jar. By this means a large amount of electricity may be collected and held by the jar until discharged by making
connection between the tin-foil on the inside and that on the outside of the jar. The electricity is held, not on the tin-foil, but on the surface of the glass. This is proved by means of a jar that can be taken to pieces after being charged—although the two pieces of metal which lined the inside and outside are now brought in contact, yet when the whole is put together again the charge is found to remain, and it is discharged by connecting the knob with the metal lining of the outside. All that these metal linings accomplish here is to make a large conducting surface over the whole of the glass upon which the electricity collects.

The discharge of electricity from such a jar, or a battery of several of them connected, produces a variety of results. The spark will pass through a thin plate of glass or a card and make a hole in them by disrupting them; or, in passing through points of metal, it heats them to a high temperature and vaporizes them, so that we get luminous effects from them. Electricity is estimated to travel at the rate of two hundred and eighty-eight thousand miles in a second.

Franklin first showed that lightning was simply a discharge of electricity from the clouds to the earth, and it occurred to him that, as points condense electricity and draw it away and discharge it quietly, lightning-rods might be made on this principle that would prevent the disruptive effects of a discharge of lightning, and so be a protection to buildings on which they were placed. Such lightning-rods are really a protection when properly made. A perfect one should be large enough to carry the charge of electricity, should have no break in it, should terminate at the top by numerous points, and connect at the bottom with the ground below the water-line, and there be surrounded by fragments of iron buried in moist earth. It is well, also, to have it connect with the metallic water- and gas-pipes running through the house.

Now, a few words in regard to dynamical electricity Galvani discovered, in experimenting on frogs, that when two pieces of metal, like copper and zinc, were placed in contact with the frog's leg and their ends connected, a movement of the leg would take place. This discovery gave rise to considerable discussion and experimentation, and, as a result, Volta developed the Voltaic pile, which at first consisted of alternate layers of zinc, wet paper, and copper, piled one on top of the other in varying numbers. It was found that, when the top layer was connected with the bottom one by means of wires, a current of electricity was set up. It became understood then that the electricity was produced by the chemical action of the water in the paper on the zinc, and so more active solvent fluids came to be used instead of water, and cloth was substituted for the paper. It was found that the zinc was the positive element here and the copper the negative, and it is usual to find in all batteries that the metal acted upon is positive, and the one not acted upon is negative. There is now practically only one metal used for the positive element, and that is zinc, for it is the cheapest and the best.

A galvanic battery is simply a combination by which we produce this chemical action, and zinc is the metal acted upon. The principle of the galvanic battery is this: If we immerse two pieces of metal, like copper and zinc, in a liquid like sulphuric acid contained in a glass vessel, and then connect the two metals by pieces of wire, a current of electricity is set up, because the liquid is decomposed by the zinc, and the $\text{II}_2\text{SO}_4$ is split up into $\text{SO}_4$ and $\text{H}_2$, and the $\text{II}_2$ is set free while the $\text{SO}_4$ unites with the zinc and forms $\text{Zn}_2\text{SO}_4$. The $\text{II}$ set free tends to collect upon the surface of the negative element, and in this way the copper finally becomes "polarized" by the hydrogen. The positive element, the zinc, always drives the positive electricity through the fluid toward the negative element, the copper.

The wires which conduct the currents from one element to the other are called electrodes, and the one coming from the zinc is the negative electrode, and the one from the copper is the positive electrode. While zinc is universally used for one element, the second element in the battery may be composed of different kinds of metals, according to convenience. A difficulty in using zinc as the positive element was soon found in the fact that little local currents were set up between it and the impurities contained in it, and this caused an unnecessary waste of the zinc. So it became customary to amalgamate the zinc in order to prevent this local action of the fluid upon it. The next improvement made was to prevent the little bubbles of hydrogen from collecting on the surface of the copper, thus keeping the liquid from coming in contact with it in all parts—that is, to prevent the "polarization" of the copper. For this purpose certain substances came to be used to absorb the hydrogen. The first of these substances was the sulphate of copper as used in the Daniell's battery. This consisted of a copper vessel containing a porous cylinder in which was suspended a rod of zinc. Dilute sulphuric acid was contained in this cylinder, and in the copper vessel outside of the cylinder was placed a solution of the sulphate of copper. In this battery the hydrogen set free decomposes the sulphate of copper, forming with it sulphuric acid, and sets free copper which collects on the copper element. Grove's battery consists of a glass vessel containing a porous cup surrounded on the outside by a coil of amalgamated zinc, and on the inside is suspended a rod of platinum instead of copper. The vessel outside of the porous cup is filled with dilute sulphuric acid, and inside with strong nitric acid. The nitric acid absorbs the hydrogen set free by the sulphuric acid and zinc. In the bichromate battery the bichromate of potash dissolved in sulphuric acid is used to absorb the hydrogen, and chromic acid is formed. So the three substances in use for absorbing the hydrogen in different kinds of batteries are sulphate of copper, nitric acid, and bichromate of potash. Bunsen suggested the use of gas carbon to take the place of the copper, or the negative element, because of its cheapness. So the Bunsen battery consists of a cylinder of carbon immersed in a vessel containing nitric acid, and within this cylinder is a porous cell containing sulphuric acid, in which a rod of zinc is suspended. To avoid using the porous cups, the force of gravity has been brought into play in the construction of the so-called "gravity battery." This consists of a glass vessel with plates of copper at its bottom, and upon this crystals of sulphate of copper are scattered, while over all is poured pure water, in the upper portion of which is suspended a

456

POST: EXTENSIVE BLOODY OPERATIONS UPON THE FACE. [N. Y. Med. Jour.,

plate of zinc. A very little sulphuric acid is added to start the battery, and then its action will keep up. Gravity here keeps the two liquids apart—the solution of sulphate of copper at the bottom, and the dilute solution of sulphuric acid at the top. This battery produces a constant current, and will run for a very long time. The Leclanché battery consists of a porous cup containing sal ammoniac in which is suspended a rod of zinc, and this cup is surrounded by the oxide of manganese as a depolarizer, immersed in which is the carbon. This battery is used when a current of electricity is desired for a very short time at once, as in striking burglar-alarms, signal-bells, etc. In the dripping battery a plate of zinc is suspended between two plates of carbon, and, when in use, these are let down into a solution of bicarbonate of potash dissolved in an excess of sulphuric acid. This fluid is called the electropoion. The galvanic battery is now being replaced for many purposes by dynamo-electric machines.

If a strong current of electricity is sent along a good conductor, it passes very easily; but, if passed along a poor conductor, it makes it hot. This is the principle upon which is based the incandescent electric light. A current sent over a fine thread of carbon heats it to a white heat, and thus produces a brilliant light. The same principle holds in the arc light, where the air acts as the poor conductor. Here two pointed sticks of carbon are placed in contact until a current is started through them, and then they are gradually separated for a short distance, when the resistance offered by the air to the passage of the electricity from one point to the other heats them to incandescence, and small particles of carbon in a state of combustion are broken off and carried through the air, thus causing an arc of light between the carbon points. The incandescent electric light and the arc light form two systems of electric lighting.

A current of electricity passed through certain substances will decompose them, and this process is called electrolysis. If it is desired to plate any object with a metal, that metal should be hung upon the positive pole of a battery, and the object upon the negative pole, and then, when an electrical current is passed through them, the metal on the positive pole will be decomposed, and a layer of it will be deposited upon the surface of the object hanging on the negative pole. This process is known as galvanoplasty.

The most convenient method of measuring a current of electricity is by means of a rotating needle, around which the current is passed; and this is called a galvanometer.

The electric telegraph is based upon the production of temporary magnets by passing a current of electricity through a coil of wire surrounding a bar of soft iron. All systems of electro-telegraphing involve a battery, a wire, a piece of soft iron surrounded by a coil of wire, a key or current breaker, and a sounder or indicator. Morse devised an alphabet, the letters of which were made up by various combinations of dots and dashes, which were scratched upon a strip of paper by the indicator. But telegraph operators soon found that they did not need to see these letters on the paper, for the ear quickly became educated to detect the letters by sound alone; so the paper was discarded, and now they hear, instead of see, the dots and dashes.

It is found that, if by any means you change the strength of the magnetism in a permanent magnet, you will at the same time change the strength of a current of electricity passing through a coil of wire surrounding the magnet, and it is upon this principle that all the modern telephones are constructed. If in front of such a magnet a thin sheet of iron is fastened, and if the plate of iron is then approached a little nearer to the end of the magnet, the magnetic center is brought a little nearer to the extremity of the magnet, and hence the magnetic power at this point is increased; at the same time a similar increase is induced in the current of electricity passing through the coil of wire surrounding the extremity of this magnet; and now, if in the same circuit of wire there is a second similarly arranged apparatus, the increased strength of the current passing through the coil surrounding the second magnet will induce an increase in its magnetic power, and hence the second plate of iron will be attracted closer to the end of the magnet. In the same way a slight withdrawal of the first plate from the end of the first magnet would cause a weakening of the magnetism in the second, and cause its iron plate to spring backward again. So, in speaking in front of the first plate, at every vibration of the air produced by the voice the plate vibrates in harmony, and a precisely identical sort of vibration is produced in the plate of the apparatus at the other end of the wire, and these vibrations can be heard as the sound of a voice. This is all there is to the Bell telephone, and it is the principle on which all telephones are constructed.

Original Communications.

THREE CASES OF
EXTENSIVE BLOODY OPERATIONS
UPON THE FACE.*

BY ALFRED C. POST, M.D., LL.D.,
EMERITUS PROFESSOR OF CLINICAL SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

By a curious coincidence, these three patients presented themselves to me within two days, requiring extensive bloody operations upon the face. The first patient was a machinist, thirty years of age, from North Carolina, who, in the month of August, 1882, was seriously burned by falling against a boiler. A large cicatrization mass occupied the lower angle of the mouth and a considerable portion of one side of the lip, extending upon the cheek. The face was very much disfigured. The cicatrization mass was included between four incisions, making a quadrilateral figure, somewhat irregular, leaving a very large gap to be filled up by the transplantation of flaps. The facial artery and a number of its branches were divided, there was a good deal of

* These cases were related briefly at a meeting of the New York Medical and Surgical Society, May 26, 1883.
trouble from haemorrhage, and the operation was necessarily a prolonged one. Flaps were made by making an incision along the base of the jaw on the side opposite the principal deformity, and another curved one pretty well up on the outer part of the face, dissecting them up deeply. The chasm was thus closed, leaving, of course, a little inequality between the two sides.

The second case was that of a man, about fifty years of age, with epithelium commencing at the lower lip near the angle of the mouth. It extended out into the cheek, in order to remove it, it was necessary to make an incision through the upper lip at the angle of the mouth, extend it horizontally outward, then downward, then inward to the inner margin of the growth. Extensive dissection of the subjacent parts was made. The operation was a very protracted one, but the immediate result was very satisfactory. The chasm was closed with very little deformity.

The third case was that of a man, about thirty years of age, who had a tumor extending over the entire alveolar process of the left side of the lower jaw, attached by fibrous adhesions, but not firmly fixed. It was of three years' standing, and was believed to be non-malignant. The tumor was exposed by making an incision through the median line of the upper lip, extending it horizontally between the lip and the nose, then vertically between the nose and the cheek, then horizontally between the cheek and the lower eyelid. The extensive flap thus outlined was drawn outward and downward, so as to fully to expose the morbid growth, which was then separated without difficulty from the alveolar portion of the jaw, to which it was attached. After the bleeding vessels had been secured, the flap was brought back into its place, and secured by numerous fine sutures. After the wound had been closed, the face was scarcely at all disfigured, as the lines of the incision had followed the natural furrows of the parts which it had involved.

Note.—October 18, 1883.—I had an opportunity of seeing all the patients after their wounds had healed. No mishap occurred to either of them, and, considering the extent of the incisions which were made, the symmetry of the face was as little disturbed as could reasonably have been expected.

Can Cancer of the Penis be Acquired by Inoculation from Cancer of the Cervix Uteri?

By Paul F. Mundé, M.D.,
Professor of Gynaecology in the New York Polyclinic, and in Dartmouth College.

Some time since there appeared in this journal the report of a clinical lecture by one of our great teachers of gynaecology, in which the statement was made, in answer to a question by one of the students, that there is undoubtedly great danger of cancer being propagated by means of sexual intercourse, and that repeated instances of cancer of the penis being contracted in this way are on record. "The slightest abrasion of the penis," the lecturer continues, "may be sufficient for the absorption of virus from the malignant growth, and the husbands of women suffering from cancer of the uterus should, therefore, always be warned against intercourse with their wives."

While the possibility of cancer being transmitted by direct contact of an abraded surface with the raw malignant growth had seemed plausible to me, and had occurred to me more than once while making examinations of women whose uteri were thus affected, I confess the assertion that cancer of the penis had actually been acquired directly from a cancerous cervix surprised me, as I was quite sure that such an instance had never come to my notice, either in print or by hearsay. As I remembered reading that experiments in the inoculation of cancerous growths on dogs had resulted negatively, it seemed to me that, if cancer of the cervix could be thus transmitted, cancer of the penis would be much more common, considering the late stage at which the malignant degeneration of the cervix usually presents itself, and the usual uninterrupted performance of the sexual act for some time, in spite of the haemorrhage produced by it. And, further, it would be very easy to elicit the fact from the husband that his wife was suffering from or had died of cancer, as soon as he was informed that his penis was afflicted with the same disease.

As my experience, of late years confined to women, failed to give me data bearing on these points, and as I was anxious to clear up, as far as possible, what seemed to me a question of great practical importance, as well as of aetiological and therapeutic interest, I wrote to a number of prominent surgeons and pathologists, at home and abroad, requesting them to answer me the following questions: 1. Do you know of any case in which cancer of the penis has been directly traced to inoculation by contact with cancer of the cervix? 2. Do you believe inoculation of cancer by temporary contact to be possible?

The gentlemen to whom I addressed these letters of inquiry were Professors T. E. Satterthwaita, W. H. Welch, R. F. Weir, and John A. Wyeth, of New York; Vincenz Czerny, of Heidelberg; and Theodor Billroth, of Vienna. All replied with the utmost promptness, and, with their permission, I reproduce the substance of their letters.

Dr. Satterthwaita, under date of September 3, 1883, writes as follows: "In reply to your note I may say that, in a published account of one hundred cases of carcinoma in its various forms ("N. Y. Med. Jour.," September, 1879), there is not a single instance given in which the disease originated from the contact of sound (i.e., non-carcinomatous) tissue with carcinoma. Still, I am inclined to agree with those pathologists who admit that contact may sometimes cause the disease, and I have in mind the case of a lady that I once took care of (in the practice of Dr. Gurdon Buck) where an epithelium of the vulva crossed from one side to the other. In this case the growth was very exuberant, and, causing much pressure upon the confronting surface, eroded it. Subsequently, another growth sprang from the eroded spot. This is the only case I have in mind."

Dr. Welch, September 13th, says: "I am sorry that I cannot give you any very definite information regarding the subject of your letter. The majority of experimenters have obtained no positive results from their attempts to inoculate cancer in animals, and the few seemingly positive
results which have been obtained are far from convincing.

B. v. Langebeek injected into the femoral vein fresh cancerous material, and a few months afterward he found cancerous nodules in the lungs; but Virchow says that they resemble primary cancer in the dog. The other positive results are not so much more satisfactory than this, so that it is generally accepted by pathologists that cancer is not inoculable from man to animals. Virchow says, however, that such negative results do not settle the question whether cancer may not be transmitted by inoculation from man to man, and I remember hearing von Recklinghausen express himself with great caution on this subject in one of his lectures. The literature of the experimental side of the infectious theory of cancer is to be found in D'Outrelepont's article in Virchow's 'Archiv,' vol. xlv. D'Outrelepont's experiments were carefully conducted and entirely negative. Nowinsky ('Centralbl. f. med. Wiss.,' 1876) claims to have produced two small growths out of forty-two otherwise unsuccessful inoculations. I do not myself know of any case where cancer of the penis has been shown to be caused by cohabitation with a woman with cancer of the uterus. I think this cause has been assigned, however, in several instances. Demarquay, in his excellent work ('Maladies chirurgicales du pénis,' Paris, 1876), analyzes, with reference to etiology, one hundred and thirty-four cases of cancer of the penis, and in only one does he find this mode of infection given as a cause. He himself does not believe in this mode of contagion. I have an idea that a careful search through the literature of the subject would bring to light other cases, but probably equally without proof.

"I have been told that von Langenbeek is a believer in this mode of origin of cancer of the penis, and that he has three or four cases which he considers quite convincing; but I am not aware that he has published them. It is possible that reference may be made to them in Wolff's dissertation, which was written, I believe, under Langenbeek's direction, although this relates to the traumatic origin of cancer.

"The question seems to me one worth ventilating, but I doubt whether any positive conclusions are likely to be reached with the data now at hand."

Dr. Weir writes: "In reply to your note of September 3d, I would say that in my own experience I have not encountered any case of cancer of the penis that could be traced to connection with a woman affected with uterine cancer. The question is not a new one, but the judgment of French observers, notably Demarquay, is against the view. Demarquay, in giving the etiology based on sixty-two cases well observed, cites one case where this cause was supposed to operate. He, however, thinks that, were inoculation possible, cancer of the penis should be more frequent than it is. Another fact is against it, which is this: that surgeons frequently, in operations for cancer as well as for other things, prick or cut their fingers and nothing evil, quoad cancer, results. It would delay my answer too long to hunt up authorities on the subject, and I therefore give you my ideas briefly as above.

"I reopen this, as I find I have omitted an answer to one of your questions, as to the general inoculability of cancer. While all my clinical knowledge is against such means of transmission, yet the latest authors, notably Cripps on Cancer of the Rectum, express a leaning toward the doctrine of its parasitic nature, especially since the heredity of the disease has been so seriously invalidated in late years."

Dr. Wyeth sent the following reply: "I have never heard of a case of cancer by contagion. It is held by some pathologists that it is transmissible by inoculation. In my own experience, or to my knowledge, I have known no case of epithelioma from coitus. Personally, I doubt the contagiousness of carcinoma. If an individual be of a cancerous cachexia by inheritance, or as a result of irritation (local), the inoculation of cancer cells might precipitate the process. I believe firmly that tumors of all kinds are chiefly caused by irritation, but I am not willing to deny that they may occur without the unnatural disturbance of a part."

Professor Czerny writes, under date of September 19th, as follows: "I am not acquainted with any case where the transmission of cancer virus from one individual to another can be asserted with any certainty, however much the well-known observations of auto-infection of cancer may incite investigations on the subject. So much is certain, that the husbands of the numerous patients whom I have seen with uterine cancer have never presented themselves to me with cancer of the penis, although I have repeatedly been asked by them as to the danger of infection.

"Likewise, I have not met with a case of carcinoma of the penis, which, it is true, are not quite so numerous, where a suspicion of cancer of the uterus in the wife could be entertained.

"The adhesiveness of the cancerous virus must certainly be very slight, and a local or individual disposition must be present in order to render such infection possible.

"Neither do I know of any case of cancerous infection of a physician, although septic infection from putrid cancerous ulcers is not so rare.

"The comparatively moderate percentage of cancerous disease in physicians and nurses, also, does not speak for contagion. Still, collective investigations of this subject would be desirable, and I am very eager to hear your conclusions."

Professor Billroth, also, under date of September 17th, writes: "Although I consider it very possible, under unusually favorable circumstances, that inoculation of carcinoma by direct contact during coition might occur, I am not acquainted with any case which would transform this hypothesis into a fact. Gynaecologists ought to have the best opportunities to make such observations."

The evidence of these experts certainly does not confirm the statement that "repeated instances of cancer of the penis being contracted in this way" (by inoculation from cancer of the uterus) "are on record." None have seen or known of such an instance; the reputed cases are questioned by the writers who mention them, and the general belief is that such infection by contact can occur only under the most favorable circumstances, i. e., when such contact is protracted, when a predisposition to cancer exists, either local or constitutional, and when an abraded surface is present. This statement applies equally to cancer in any portion of the body. The comparatively short period of con-
RAPHAEL:

soon the healed, upon years states possible, and met thin, The coming cheek of instance ing, ailingly, Oct. 27, 1883.

Did such short contact of an abraded living surface with a cancerous ulcer suffice for the inoculation of that disease, surely the gynaecologists—whose index-fingers can not always be protected from slight injuries, and who, unknowingly, examine many women with cancer of the cervix, making that very diagnosis by such digital examination—would long ere this have become inoculated with it. But no such instance is recorded.

While thus the first authenticated, unquestionable case of inoculation of the penis with cancer cells from a cancerous cervix seems as yet unpublished, and while it is still doubtful whether such inoculation actually takes place, still the possibility of such an occurrence can not be denied, and I trust this communication may induce gentlemen who have met with cases in point to place them on record. Certainly the subject is of sufficient interest and importance, clinically and pathologically, to merit further investigation, and, if possible, ultimate positive elucidation.

A CASE OF TUBERCULAR SYPHILIDE OF THE FACE.

By H. RAPHAEL, M. D.,
ATTENDING PHYSICIAN FOR DISEASES OF THE GENITO-URINARY ORGANS AND STIPHILIS, BELLEVUE HOSPITAL, OUT-DOOR DEPARTMENT.

A merchant, aged thirty-four, married, a native of the United States, and the father of three healthy children, states that he always enjoyed good health, never had any eruption, but had a sore on his left leg when he was fifteen years old. He solemnly asserts that he never had any illicit intercourse, nor ever exposed himself in any way whereby he could contract specific disease. About eight years before coming under my care he had a sore over his left eyebrow which refused to heal by the use of various remedies, and, upon applying to a physician, he was told that it was lupus. The sore continued to spread, notwithstanding the use of caustics, until it involved the lower half of the forehead to the external angle of the right eye and the temple, destroying almost all the hairs of both eyebrows. The sore finally healed, leaving the skin over which it had traveled very thin, pale, and somewhat wrinkled, resembling very much the goose’s skin. Since then he has been troubled more or less with sore throat, mostly during the winter months.

About two years ago, he says, a sore similar in character to the one on his forehead formed on his right cheek, midway between the ala of the nose and the cheek bone, which shortly afterward began to suppurate and to discharge thin pus; soon assumed an angry, red, inflated appearance, spreading farther and farther until it extended up over the malar bone to the bridge of the nose, to the angle of the eye, and downward to the upper lip and lower part of the cheek to where his whiskers grew. For this he was treated by some physicians for lupus with caustics, by others for cancer with various remedies.

In February, 1882, when he applied to me, the ulceration had spread almost all over the right half of the face and upper lip, extending into the right nostril. The edges of the ulcer had a red, angry look, and were thickened and elevated above the general surface; the ulcer was irregular in form, and the ulcerated surface discharged a slightly thin ichor, and all around it, near the inner edges for three or four lines, the surface was redder than the rest of the ulcer. Here and there were several small ulcers, not joined to the larger one, having the same general character of the latter, which the patient said had existed for some time without manifesting any tendency to coalesce. His general condition was poor; he was much run down and anemic, his appetite was poor, and he was much depressed in mind on account of his trouble. He was also suffering from ulceration of the posterior wall of the pharynx, resembling that on his face.

Though there were no other evidences pointing to a specific character of the disease, and although the patient solemnly averred that he had always been chaste and virtuous, yet the general character of the lesion was such that I felt justified in putting him upon the use of specific remedies, mainly the bichloride of mercury and the iodide of potassium. By the first of April his face was completely healed, with the exception of a very small spot, when he exposed himself to a drenching rain, and that brought on an attack of erysipelas of the right half of the face, extending to and involving the upper and lower eyelids, forehead, ear, and scalp, with pain, redness, and swelling of the parts involved. For this he was treated with large doses of muriate of iron, stimulants and tonics internally, and the usual topical applications. In about two weeks he was so far recovered from his erysipelas as to be able to resume the specific treatment for the ulcer of his face, which had again spread considerably.

I lost sight of him in the early part of May, and did not see him again till the 12th of October, when he again presented himself with his face completely ulcerated, the ulcer extending over the entire surface described above, and this had happened, he stated, in a few days only. When he stopped treatment in May previous, he supposed himself to be entirely cured of his disease, for the ulcer, he said, was almost entirely healed. Dr. Bulkley was kind enough to see the patient, and confirmed the opinion as to the specific nature of the disease. The patient was again placed upon the use of bichloride of mercury and iodide of potassium, with iron and a zinc preparation locally, under which treatment the ulcer healed up completely, leaving a somewhat thickened scar, stellate in form, running obliquely from the cheek toward the inner angle of the eye.

March 5, 1883.—Patient again presented himself to-day, with an oblong ulcer of about three quarters of an inch in length and a quarter of an inch in width on the posterior wall of the pharynx, but otherwise in excellent health. Under the use of specific remedies this also healed up rapidly, and he has since remained well.

The Ode of Iodoform.—According to a writer in the “Gazette hebdomadaire de médecine et de chirurgie,” the use of eucampane to mask the odor of iodoform is a failure.
Clinical Reports.

NEW YORK HOSPITAL.

VARICOCELE.—INTERNAL URETHROTOMY: THREE CASES.

Clinical Remarks, September 15, 1883.

By Robert F. Weir, M. D.

VARICOCELE.—Gentlemen: There are four patients whom I shall present before you to-day, one suffering from varicocele, and the three others from urethral stricture. Two of the latter present a very similar history, and in each case the operation to be performed is that of internal urethrotomy.

In the case of varicocele, the usual symptoms which are liable to attend this affection have been causing the patient a good deal of suffering, and demand an operation. The symptoms are: pains referred to the rectum and thigh, mental unsteadiness, and a change of nutrition in the testicle, which has as yet only led to slight softening, but may finally result in atrophy, etc. I consider the commencement of atrophy a sufficient indication for operative interference, although the other symptoms may not have become troublesome. I will not enter upon the subject of the causation of the atrophy which may take place, nor upon that of the more frequent occurrence of varicocele on the left side than on the right, further than to say that the explanations hitherto offered, based upon the anatomy of the parts connected with the affection, are not altogether satisfactory. Different methods of treatment have been resorted to. When in the hospital, before it was removed to its present situation, in a number of cases I did the operation of packing up the scrotum, lessening its size by excising a piece of the over-distended tissue. But, although the result was quite favorable for a time, in some instances in which I was able to keep track of the patients, the stricture again became distended and called for further treatment. Another method of treatment, but not radical, consists in suspending the scrotum by a bandage, and for this purpose none is better than the army suspensory bandage. Since the introduction of antisepsics, I have more frequently resorted to ligation of the veins on the affected side by passing a ligature through the scrotal tissue in front of and behind them, not including the vas deferens, and tying them, thus setting up a sufficient amount of inflammatory action to cause their contraction. The parts are washed and dressed antisepically. That is the operation which I propose to do in this case. Springs, composed of some sort of string or wire, and so made as to cut through the tissues in a certain number of days, have been invented to effect a similar purpose.

INTERNAL URETHROTOMY.—The first patient, with stricture of the urethra, gives a history dating back ten years, when he contracted his first gonorrhea; since then he has had two more attacks. The third time a gleet remained; finally stricture took place, for which, some years ago, internal urethrotomy was performed, and the man was provided with a sound, which he continued to pass for a period, then discontinued it, and recontraction took place. The urine, a few months ago, began to pass in a very small stream, and shortly afterward dribbling occurred at the end of the act, indicating that there was distension of the urethra back of the constriction, in which the urine accumulated, and at the close of urination came away by drops—not having brought to bear upon it the expulsive force of the detrusor urinæ. We are able to pass a filiform bougie through the stricture, which is found to be located in the membranous portion of the urethra, just anterior to the triangular ligament. In this case, as in all cases, we examined the urine carefully, to see that there are no signs of kidney disease; and, with the more delicate test for albumin than the nitric-acid test which we at present possess in piecic acid, we are able to do this with a considerable degree of certainty. This patient is not entirely free from the indications of the nerves element which sometimes leads even to a fatal issue after this operation. On one or two occasions he has had something like a faint after the passage of the sound, but this tendency has been largely diminished by the frequent passage of the instrument.

The history of the second patient corresponds closely with that just given—strictures resulting from a gonorrhoea contracted some years previously. In this case, however, there are two strictures—one situated in the anterior portion of the urethra, and the other at about the same position as in the case of the first patient. They are both of larger caliber than in the first case, but are very yielding, and for that reason call for division. [In both these cases Maisonneuve's instrument was passed over the whalebone guide, and the stricture was divided up to a point admitting a No. 32 sound.]

The third patient also has a history of gonorrhoea, but the stricture exists only in the anterior portion of the urethra, at a point about three inches and a half from the meatus. The cicatricial tissue can be distinctly felt by the finger at the peno- scrotal junction. Division was performed some years ago, but recontraction took place. By dividing the cicatricial tissue I hope to obtain a more permanent result.

[The further history of the cases will be given in a subsequent report.]

Book Notices.

The third and last volume of this great and important surgical work deals with diseases of the larynx, trachea, mouth, and associated parts; with diseases of the eye and ear; with malformations and deformities, and affection of the muscles, tendons, and salivary glands; with surgical affections of the nerves, the lymphatic system, the skin and subcutaneous tissue; with syphilis, tumors, and diseases of the mummy gland; and finally, special chapters are devoted to the surgical applications of electricity, to the operations of nerve-stretching, and to massage.

It will be seen at once from this enumeration, and from a glance at the two preceding volumes, that the author has attempted nothing less than the enormous task of writing a complete text-book of modern surgery in all its branches—a task which might well make the most industrious worker hesitate, and one which in Holmes's and Ashhurst's works has been portioned out among a number of men, each supposed to be specially fitted for the subject he deals with. But Dr. Agnew is a surgeon of the old school, and the growth of specialties is a recent thing. He would, probably, no more hesitate to do an iridectomy than to write a chapter on diseases of the eye.

It has been generally admitted for some time that the field of surgery is too vast for any one man to compass, either in theory or in practice; but whatever one man can do to refute this idea has been done by Dr. Agnew in the present work. It is the best of its kind of which we have any knowledge. It is better than any other surgery written by any single author, and
better than many of the encyclopedias. It can only be judged fairly by taking special parts, and comparing them with special works on the same subject. The chapter on syphilis must, for example, be placed side by side with the works of Van Buren and Keyes, and of Bunstead and Taylor; that on diseases of women with those of Thomas and Emmet; that on the eye with that of Wells; and that on the throat with Mackenzie's book. But, as the specialist in any of these branches would not go to Dr. Agnew's work for information, in all probability the general practitioner would not go to their works, but would seek the information necessary for general practice in some such book as this. For this we judge the book has been written, and this mission it certainly fulfills.

Any one familiar with modern surgery will be convinced, before looking into this work, that the author could not have collected everything, even in three such volumes as these; but he will probably be surprised to see how much has been collected, and with what excellent judgment the selection has been made; how nearly everything of any real and definite value has been gathered up and incorporated under its proper head. For example, let the specialist in diseases of the throat look over the first one hundred and forty pages of this volume, and see how little which pertains to this subject has been omitted. Not only are the more common affections given, but such things as lupus, lepra, extirpation of the larynx, affections of the nasal septum and the operations for their relief, deformities, tumors, and neuroses. So it is in the next one hundred and ninety-two pages, devoted to diseases of the eye and ear.

The chapter on malformations and deformities is particularly noticeable for the number, value, and originality of the illustrations. Wry-neck is included under this head, and the deformities of the fingers and toes are described and illustrated, as well as those of the ankle and knee. At the very end we find a valuable paragraph on division of the spinal accessory nerve. The chapter on the muscles includes not only wounds, laceration, and rupture, but paresis, myositis, degeneration, parasitic cysts, tumors, thecitis, ganglions, and sarbitis, each dealt with concisely, but fully and authoritatively.

Under the Surgical Affections of the Nerves we find twelve pages of tabular matter, comprising the literature of nerve-stretching for the various affections to which it is applicable, such as scoliosis (sixty-one cases), traumatic neuralgia (twenty-six cases), neuralgia of the fifth nerve (thirty-five cases), traumatic tetanus (forty-six cases), mimic spasm (eighteen cases), miscellaneous neuralgia affections (thirty cases), central disease (one hundred and six cases), torticollis (thirteen cases), paralysis (forty-four cases), epilepsy (four cases), disease of the optic nerve (eight cases), and contracture and spasm (five cases).

Under the head of Diseases of the Lymphatics we find all that is known of these rare diseases, while the part devoted to the skin and subcutaneous tissue includes only the surgical diseases, such as erysipelas, horns, warts, keloid, elephantiasis, and tumors, with affections of the hair and nails. Under Afections of the Thayroid there is a table of seventy cases of extirpation.

The chapter on Syphilis covers seventy-five pages. The work has been carefully and thoroughly done, and includes Syphilization, Infantile and Hereditary Syphilis, Syphilis and Marriage, and a short note on the Regulation of Prostitution.

In the chapter on Tumors the author acknowledges the assistance of Dr. Forman. It covers just one hundred pages of richly illustrated matter, most of the microscopic drawings being original. The remaining chapters of the work are devoted to the mammary gland; to electricity and electrolysis; to the various operations of nerve-stretching, each of which is illustrated; and the work closes with a practical chapter on Massage.

Well may Dr. Agnew congratulate himself on the termination of his long task. When we remember that the present volume of nearly eight hundred pages is only one of three; that there are nearly 2,200 illustrations, the majority of them original; and that every branch of surgery has been included, the magnitude of the task begins to be apparent. The book represents the study and experience of a lifetime, and we have nothing to say except in praise for the work itself and congratulations for its distinguished author.

Second Notice.

In his first chapter, on the Nature and Seat of the Mind, Dr. Hammond deals very clearly and fairly with what is often reproached as "materialism," arguing that a misunderstanding has arisen from the mind having been confounded with the soul. With the latter, he remarks, science has nothing to do, while theologians step beyond the proper sphere of their theme when they descent of the former.

Except for its charming style, we find only one more subject for notice in the chapter, and that is Dr. Hammond's pointed statement that the excretion of alkaline phosphates is an exact index of the amount of brain-work that has been performed during the process of their elimination—a view generally held, but one that was sharply questioned, it may be remembered, in a paper read at the recent meeting of the American Neurological Association.

But we must pass over the introductory matter with but few more comments, for, were we to linger as its interest tempts us to linger, this notice would be too protracted. We think the author would have done well to describe the various temperaments in less positive terms than he has chosen, for in fact they are seldom so clear-cut as to answer at all closely to the stereotyped delineations that have come down to us from times when the imagination played a leading part in scientific writing.

While on the subject of the tender age at which insanity sometimes shows itself, Dr. Hammond speaks of an interesting case in which he trephined a maniacal boy six or seven years old, with prompt relief. There was an obscure history of a fall in infancy having injured the head, but no injury was discovered at the time of the operation. The author is inclined to think that moral and emotional disturbances, without marked intellectual aberration, are more common in girls than in boys. In regard to the influence of the sexual functions upon insanity, he says he has never known marriage entered upon for the purpose of curing insanity, but has repeatedly had it suggested to him for his opinion, and has always advised against it. This course certainly seems most appropriate, and the only legitimate one to pursue.

Many a reader of "Tom Jones" has doubtless lingered longer over the digressions than over the thread of the story, and we must confess that Dr. Hammond's digressions are every whit as attractive as Fielding's, and so far-reaching that we find ourselves wondering whether we are not reading a cyclopaedia, rather than a medical treatise. We will confess, indeed, that it is to the fondness with which we have dwelt on those portions of the book that did not invite criticism that the length of time which has elapsed between our first notice and this concluding one is to be imputed. But we must at last take leave of our author's bewitching prolegomena, and settle down to his subject proper. And, first, as to his definition of insanity. After quoting and criticizing those of many who have preceded him, he

Oct. 27, 1883.] BOOK NOTICES.
gives the following as his own: "A manifestation of disease of the brain, characterized by a general or partial derangement of one or more faculties of the mind, and in which, while consciousness is not abolished, mental freedom is weakened, perverted, or destroyed." This definition implies that what we call the mind is a product of cerebral action, rather than its ruling power—a conclusion that is unsatisfactory to our estimate of ourselves, albeit one that it is difficult to refute, and one that science is more and more coming to recognize.

After giving the best-known systems of classifying the various forms of insanity, and stating with the utmost candor and appreciation what he considers to be their defects, the author lays down his own classification as follows, premising that he does not regard it as faultless:

I. **Perceptional Insanities** (in which there are derangements of one or more of the perceptions).
   a. Illusions.
   b. Hallucinations.

II. **Intellectual Insanities** (in which the chief manifestations relate to the intellect, being of the nature of false conceptions [delusions], or clearly abnormal conceptions).
   a. Intellectual monomania with exaltation.
   b. Intellectual monomania with depression.
   c. Chronic intellectual mania.
   d. Reasoning mania.
   e. Intellectual subjective morbid impulses.
   f. Intellectual objective morbid impulses.

III. **Emotional Insanities** (in which the mental derangement is exhibited chiefly with regard to the emotions).
   a. Emotional monomania.
   b. Emotional morbid impulses.
   c. Simple melancholia.
   d. Melancholia with delirium.
   e. Melancholia with stupor.
   f. Hypochondriacal mania, or melancholia.
   g. Hysterical mania.
   h. Epidemic insanity.

IV. **Votitional Insanities** (characterized by derangement of the will—abnormal predominance or inertia).
   a. Votitional morbid impulses.
   b. Aboulomania (paralysis of the will).

V. **Compound Insanities** (forms in which two or more categories of mental faculties are markedly involved).
   a. Acute mania.
   b. Periodical insanity.
   c. Hebephrenia.
   d. Circular insanity.
   e. Katatonia.
   f. Primary dementia.
   g. Secondary dementia.
   h. Scirle dementia.
   i. General paralysis.

VI. **Constitutional Insanities** (the result of a pre-existing physiological or pathological condition, or of some specific morbid influence affecting the system).
   a. Epileptic insanity.
   b. Puerperal insanity.
   c. Pellagrous insanity.
   d. Choreic insanity, etc.

VII. **Arrival of Mental Development.**
   a. Idiocy.
   b. Cretinism.

The subdivisions are not included in the formal list, but are considered in treating of each particular form. It will be seen that this classification is open to the criticism that it is partly clinical and partly pathological, the former factor predominating.

It must be said, however, that any single basis of classification is scarcely warranted by our present knowledge of the subject. It is questionable, indeed, whether, as in some other branches of medicine, it would not be best for the present to stop at nomenclature and leave classification to the future. Still, a classification is a convenience in a text-book, even if faulty, and, its imperfections being acknowledged by the author, none but the blindest of readers are liable to be misled.

From this point onward, until we come to Chapter IX, the book is almost wholly descriptive, the argumentative portion being so artfully interwoven with what may be called the narrative that it will, no doubt, affect most readers insensibly—at least automatically. In this art the wealth of illustration brought into play is turned to the utmost advantage. The possession of such literary skill is dangerous in a scientific writer, since it enables him to carry the unlearned with him in spite of all opposition. We are bound to confess, however, that Dr. Hammond has not prostituted his power to propagandism. He makes no dogmatic statements that do not seem to him plainly deductible from the facts. At the same time, by avoiding ostensible argument for the most part, he makes sure that what he writes will be read through. It must not be supposed, from what we have said, that Dr. Hammond's personal opinions do not stand out; they do, but not with undisguised prominence. There is, however, no ambiguity about the book. If the limits of our space allowed, it would be interesting to allude specifically to many of the author's views on unsettled points, but we will content ourselves with a bare reference to the confirmation he finds of his idea respecting the connection between reasoning mania and general paralysis in the lesions of the cerebral blood-vessels found in the case of Guitet.

Dr. Hammond agrees with nearly all writers in regarding the excessive use of alcohol as foremost among the causes of insanity; but he is very positive in denying that insanity due to this cause presents any distinguishing features in its clinical history—an opinion which, he frankly confesses, is the opposite of the one he entertained formerly. He is careful to distinguish between insanity proper and an abnormal appetite for alcohol, opium, chloral, etc. Sunstroke he does not regard as so common a cause of insanity as is popularly supposed, but he allows that it plays a considerable part.

In Chapter X, on the Prognosis of Insanity, there is little to remark, except the vigor with which the author uses Dr. Pliny Earle's demobilization of the significance of asylum statistics.

In the next chapter, on the Diagnosis of Insanity, Dr. Hammond expresses himself very sensibly and very forcibly as to the distinction between insanity and irresponsibility. There is much more in the chapter that would well repay analysis, but we must pass it by, as well as the succeeding one on the Pathology and Morbid Anatomy of Insanity.

This brings us to the closing chapter of the book, on the Treatment of Insanity. The most noteworthy feature in the chapter, and the only one we have space to notice, is the answer given to the question, Shall the insane person be treated at home or in an asylum? In reference to this question, Dr. Hammond divides patients into these three groups: 1. Those who should never be committed against their will (those affected with perceptual insanity, including illusions and hallucinations; with intellectual subjective morbid impulses; or with aboulomania). 2. Those of whom a minority may require commitment (with intellectual objective morbid impulses; with emotional monomania, emotional morbid impulses, simple melancholia, hysterical mania, or epidemic insanity; with votitional morbid impulses; with katatonia, primary dementia, or senile dementia; or with puerperal or choreic insanity). 3. Those of whom a majority may require to be so committed (most of those with intellectual mono-
Correspondence.

LETTER FROM BOSTON.

The Veterinary Hospital.

BOSTON, October 20, 1883.

The Veterinary Hospital is situated at the south end of the city, and is a three-story building of brick, with freestone trimmings. It is the most commodious and best-appointed structure of its kind in America. In the construction, the use to which every part was to be devoted was kept well in mind. The basement is fitted up in part with stalls for cows, while the rest will be occupied as a blacksmith’s shop. On the first story there are
the offices for the surgeon. Eleven stalls, one of which is padded, are provided for horses, the rest of the space being devoted to an operating- or examining-room, a large well going from this floor to the roof furnishing the necessary light. The second story has a few stalls for horses, but is largely given over to dogs and other of the smaller animals. The rest of the floor is divided into rooms for the attendants, for the pharmacy, and for the cases where the surgical instruments are kept. The third floor has quarters for the house surgeon and others, and will also be used for storage purposes.

Advantage is to be taken of this hospital for clinical instruction to the students at the veterinary department of Harvard University; and yet the laboratory work is to be done and didactic instruction given in part at the Medical School building in Boston, and in part at the Bussey farm, in West Roxbury, six miles from Boston, where the agricultural department of the university is located.

It seems as if a better arrangement could be made—one by which all the instruction could be given, so far as practicable, under one roof, for much time must necessarily be wasted according to the present plan. The faculty seem to think that the branches of physiology and pathology can be studied to as good advantage at the Medical School with those studying general medicine as if the instruction was given separately. In Europe, generally the students of both human and veterinary medicine have studied the preliminary branches together; but the authorities in Germany, not being satisfied with the results from such a classification, have lately appropriated $100,000 for the erection and fitting out of two laboratories—one for physiological, the other for pathological work—for those pursuing veterinary science, thus showing in a practical manner that they believe each department should be separate. To show how the Harvard Veterinary School expects to raise funds, let me quote the following from its announcement:

Annual Subscribers.—To each subscriber of ten dollars a year (the year beginning June 1st, and payment being made in advance to E. W. Hooper, treasurer, 79 Water Street, Boston), the following privileges will be given in connection with the establishment:

1. Each subscriber may have admitted to the hospital for medical or surgical treatment an unlimited number of animals, his own property, at a charge for keep and medicines only (not exceeding $1 a day).
2. He may procure without charge the opinion of the surgeons of the school as to the treatment of any animal which he may desire to retain in his own possession, whenever an opinion can be given without examining the animal away from the establishment.
3. He may have ten horses examined as to soundness in the course of the year, and procure the opinion of one of the surgeons therein, either verbally or in writing, free of charge. Under this contract patients will not be visited, and horses will not be examined for soundness away from the establishment.

The circular from which this was taken was freely distributed about the city to those likely to be interested in the subject, and drew out a spirited letter from Dr. Frank S. Billings, well known, not only to the readers of the Journal, to which he has contributed numerous articles, but to all those interested in the progress of veterinary science. The letter spoken of was published in the “Saturday Evening Gazette” of May 5, 1883, and contained the following extract from an article written by Dr. George Fleming, editor of the “Veterinary Journal,” and published in that paper:

Our readers will have observed that for some months an agitation has been going on among the members of the veterinary profession, chiefly metropolitan practitioners, with reference to the unfair competition maintained toward them by the Royal Veterinary College, London, known as the subscription system. As is well known, and as so many veterinary surgeons find to their cost, this school advertises that for two guineas a year it will examine seventy horses for soundness, give advice with regard to an unlimited number, receive into the school hospital and treat sick horses, as well as sell medicines at cost prices, shoe horses for a smaller sum than the ordinary farrier can, etc; while for five guineas per annum an indefinite number of horses will be examined, and all other privileges guaranteed. In fact, it offers to do what no practitioner can afford to do, and undersells its own students to such an extent that it is not only impossible for them to compete with the cheap establishment, but the bread is actually taken from their mouths by this so-called alma mater of theirs. It has been said that the French revolutions cut up their own children. The London school does this and more—for it charges them heavy fees for tuition, then starves and swallows them.

Had the school never been begun on this system, there can be no doubt that later it must have been established by the country for the benefit of the country. In this case, veterinary medicine would have all along stood in a very different position to what it has done and does now, and millions of pounds would probably have been earned. A desire to get hold of money has been the bane of the school, as it has been its chief aim; hence the degrading subscription system, and the determination to continue and extend it, no matter who suffers, whether it deprives the veterinarian or the blacksmith of his means of livelihood.

Surely the noblemen and gentlemen who lend their names and patronage to this school are not aware of the fact that it is not a scientific institution, nor yet a college, but merely and mainly a great cooperative horse-doctoring and horse-shoeing concern, devised to benefit wealthy subscribers, having nothing to do with the introduction of humane or improved methods of treating disease or accident, and doing its business in shamefully cheap principles.

We may be told that the subscription plan is necessary to the existence of the establishment, and that, without it, it must perish of starvation. If such a statement is correct—and we do not deny it—then it reveals a very discreditable state of affairs. No other veterinary school in these islands requires to resort to such ignoble stratagem to live; no medical school does, or dares to, undercool practicing physicians; in fact, the London Veterinary College is the only medical or veterinary school in Europe which, like a huge parasite, lives and grows at the cost of its graduates, past and present. The “subscription system” has been the curse of our science, and its malignant influence can be traced through long years and in many directions. It is unprofessional in every sense of the term; it is derogatory and damming to veterinary medicine, and in every way disadvantageous to the student and a discredit to the governors (of the school) and the country.

Though the foregoing remarks were written concerning the London Royal Veterinary College, they are as applicable to Harvard, and it seems as if, with the amount of money at the disposal of the University, and the readiness with which it can obtain funds when it makes a public demand, some other plan than the one adopted might have been tried. If the same policy should be attempted in the medical department there would be a great hue and cry, and physicians would unite to deprecate the attempt. Yet what is right in one case should be right in the other, and it is most earnestly to be desired that a change in the manner of raising funds should be made. The excuse can not be given that these means are necessary to obtain the material for clinical instruction, for by the free system, on the same principle as in hospital outpatient departments, the want would be supplied.

LETTER FROM CINCINNATI.

Medical Legislation in Ohio.—Medical Ethics.—The Medical Colleges.

CINCINNATI, October 15, 1883.

The recent State election has given us a Democratic Legislature. This fact is worthy of mention in a letter such as this one.
in consequence of its possible relation to future medical legislation in Ohio. If the Democratic party is consistent in follow-
ing a policy directly opposite that of the Republican party in matters medical as well as political, the present revolution in our State government promises well for the friends of medical and sanitary reform. This remark calls, perhaps, for more explic-it statement regarding the condition of State medicine in Ohio, and the relative responsibility of the two parties for our shameful conservatism.

Ohio has no State board of health, nor has it a law worthy the name regulating the practice of medicine. As a result, the State is in a deplorable condition, being the camping-ground, if not the permanent abiding-place, of the quacks driven by whole-some legislation from other States. Illinois has become famous for her salutary medical laws and their vigorous enforcement. Indiana has taken a wise step in the same direction; so, indeed, have Michigan and West Virginia, while Kentucky is not so conservative as her Board of Medicine would imply. Thus the unquali-fi ed practitioners, the blatant quacks, the itinerant "tapeworm artists," and the traveling "cancer doctors," are driven from every side into Ohio, where the only statute that confronts them is one declaring that they can not collect their fees at law unless they are qualified practitioners—that is, either graduates in medicine or practitioners of ten years' standing! Is this not marvelous for a State so progressive as Ohio is presumed to be? and ought it not to bring the blush of shame to those who are responsible for the condition?

An effort was made in the last Legislature to secure a law meeting these unfortunate conditions. A bill was prepared and introduced into the House corresponding in every important particular with the law that has proved of such value in Illi-

No. It stipulated, however, that the Governor, who was to make the appointments for this board, was to select representa-
tives of each of the recognized so-called "schools of medicine." These schools were not specified as "regular," "eclectic," "homeopathic," "physio-medical," "vitalpathic," "electro-
pathic," and so on, leaving it with the Governor to determine what was meant by "recognized schools of medicine." This particular clause was unsatisfactory to the medical hoodlums, who at once became distrustful of the appointing power; each individual Arab became apprehensive that his particular sect would not be recognized; the common quacks were opposed to reform on general principles. As a result, the irregulars of all kinds and degrees followed Dennis Kearney's advice, and, in the language of that famous reformer, "poled their issues!" They made a concerted attack upon the Legislature, and that magnificent hippodrome of ignorance, conceit, demagogy, and venality capitalized without parley. The bill was put to a final vote, and the feeble support it received was buried beneath an avalanche of negatives. That Legislature was Republican, and the record made in this matter should put the grand old party of reform to the blush. An effort will be made again this year to secure the passage of this much-needed law, but with what result remains for the newly triumphant Democracy to determine.

You in New York do not hear much concerning ethics in Ohio or the West, and I presume you are thankful, as you have quite enough of that subject at home. We are not indifferent to the issue that is being joined in the Empire State, nor are we indifferent to what is of more importance—namely, the general subject of ethics. The Ohio State Medical Society has given no formal expression on this matter. Nor have our local societies, so far as is generally known, taken action concerning the modification of the national code. The question of change is not, therefore, at present an issue, but I predict that the time is not far off when the conflict will come. The prominence of your New York fight has made the topic one of general conversation,

and, as a consequence, physicians are thinking, their views are widening, and presently their conclusions will crystallize in action.

After viewing the field carefully, my judgment being based upon an intimate acquaintance with physicians living all over the State but chiefly in the southwestern section, I am led to the conclusion that the adherents of the two sentiments are capable of quite definite classification. Those in favor of the old code—the conservatives—are made up of several elements, viz.: those who are constitutionally opposed to any change in principle (chiefly very old doctors); those who would like to change but will not do so to avoid an appearance of stultification (also old doctors); those who believe in the ostracism of any man who does not think as they do (implications of all ages); those who think as their fathers thought for no other reason than that their fathers did think so (generally young men of tardy adoles-
cences)—these, with a few subdivisions, comprise the class of con-
servatives. Those in favor of a change—the reformers—are also made up of several classes, viz.: those who believe in the largest possible personal liberty compatible with the general good (representatives of all ages); those who believe that the old code has fostered schism and kept the profession at the farthest re-
move from unity (generally observant old physicians with moral courage enough to acknowledge their convictions); those who are convinced that under the advanced teaching in "irregular" schools the education imparted is not widely different from that given at the orthodox institutions (generally the younger ele-
ment of the profession who have had the temerity to examine into the question); and, finally, those who have come into the profession since the code was framed and since the rancorous animosity prompting it has died out, and who, having had no voice in framing its provisions, refuse to accept it as the ex-
ponent of their ethical faith (progressive young men in and out of the medical societies, the latter of whom are anxious for an opportunity to vote on this question). This classification, which might be amplified, represents opinions which are to be found among the reformers; and around these opinions conviction is rapidly crystallizing. The conflict is inevitable, and its outcome can not be doubted; the ear of progress rolls ever onward.

The medical season is now thoroughly opened in Cincinnati. The schools are in good working order, their professors hard at work, and their students attentive and studious. Some changes have been made in the faculties. At the Cincinnati College of Medicine and Surgery, Dr. J. H. Hazard has been made Profes-
sor of Physiology, and Dr. W. K. Boylan has been elected to the chair of Materia Medica. These are both young men of some years' standing in the profession, and bring matured judg-
ment along with zeal and enthusiasm in the discharge of their duties. Professor George B. Orr, of the chair of surgery, has just returned from New York and other eastern points, where he has been spending his time at the hospitals, when not engaged in catching blue-fish at Block Island. At the Medical College of Ohio no changes of importance have taken place, but it is generally understood that Professor Dawson, the veteran sur-
gon, will soon retire, to give place to his more active colleague, Professor Lanzhoft, now holding a chair of minor importance in the faculty. The attendance at the various schools is not as large as last year, and has not fulfilled the expectations entertained by the different faculties. The Medical College of Ohio has, as usual, the largest class, but the Cincinnati College of Medi-

The making of doctors has already been in excess of the demand, and it is time the mills run at slower speed and with smaller grists.

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, OCT. 27, 1883.

THE ELECTION AT THE COUNTY SOCIETY.

Nothing could be more complete than the victory won by the opponents of the code of ethics of the American Medical Association last Monday night, on the occasion of the annual election of officers of the Medical Society of the County of New York. By majorities ranging, in round numbers, from one hundred and fifty to one hundred and seventy-five, in a total poll of five hundred and ninety-nine, every man on the ticket was elected. The result appears particularly striking when we reflect that the defeated ticket was headed by a man of such renown in the profession, and of such rare personal magnetism, as Professor Thomas. When we chronicled his nomination, some weeks ago, we expressed our view that his election, on the strength of his personal popularity, was not at all unlikely, and we warned our readers not to interpret such an event in any other way than as a tribute to the man—not to look upon it as necessarily any sign of a revulsion of the prevailing feeling on the code question. This caution has proved unnecessary. The men who in the past had signified their devotion to the cause of the Medical Society of the State of New York, as against the misrepresentation, slander, abuse, and petty persecution heaped upon the New York profession in its corporate capacity by sister organizations, by editorial writers, and by individual busy-bodies—the men who have resisted these influences in the past have not on this occasion suffered themselves to be lured from their course by personal considerations. As Dr. Flint, Jr., remarked when he announced the old-code party's nominations, it has been a question of measures, not of men. The victory allows of no misconstruction. So far as ordinary foresight is of any value, it forebodes the certain defeat of any attempt in February to reverse the stand taken by the State society.

It cannot be said that the triumph of the opponents of the old code was in any degree accidental, that it was favored by side-issues, or that it was gained by tactics. The meeting was thoroughly advertised; the purpose of the struggle was perfectly understood by every member of the society; the assemblage was one of the largest that have ever taken place in the whole history of the society, if it was not the very largest. The number of ballots actually cast lacked but one of a round six hundred, and many men are known to have “paired off.” There were no questions of detail—it was a plain and square issue, for or against the old code; and both sets of candidates were men whom any medical society in the world would be proud to have for its officers. There was no scope for parliamentary fencing—no voter was in the slightest degree befogged, nor was any attempt made in that direction. It is true that a charge of bribery was hinted at, but not with even enough show of justification to engage the serious attention of either side. Granting, even, that Dr. Oberndorfer's statements were warranted by facts to the fullest extent, no charge of bribery could lie unless the bribery were attempted on a voter, and Dr. Oberndorfer only maintained that an Indecent had been held out to a person to join the society, and that the person in question declined.

One fact should be noted here, since at first sight it may seem singular. We refer to the undeniable circumstance that a large number of men who had signed the old-code declaration voted against the old-code ticket. This, it seems to us, must be explained either by the fact that the terms of that declaration did not commit its signers to the extent that has been taken for granted, or by assuming that many of those signers were disgusted at the failure to remember the implied promise contained in it on the occasion of the meeting of the American Medical Association in Cleveland. The action of the Academy of Medicine, last week, in rescinding the resolutions passed last spring may have strengthened some who were disposed to waver—for there are always a few who will vote with the party that seems to have the best chance of winning—but we are inclined to think that its influence was practically inconsiderable.

It seems a fair inference, then, and one that is no less a matter for congratulation than the central fact itself, that, in spite of the petty scheming and the resort to parliamentary devices of which so much has been said, the division of the profession on this question of codes is, as it now stands, one of honest difference of opinion. The sooner that fact is recognized, the sooner we shall be out of the undignified position we have occupied, before the public for the past year or more. Another satisfactory feature of the matter is daily becoming more and more obvious: the fact, namely, that, as we have all along insisted, and as Dr. Barker gracefully suggested in the impressive remarks with which he accepted the defeat of his proposed amendments to the constitution and by-laws of the Academy, the difference of opinion that exists among us is not as to the principles of ethics, but as to the wholly secondary matter of codes. Each party reckons among its adherents, in about equal proportions, men who have achieved honor for American medicine and an honorable fame for themselves; and each side is burdened, also in about equal proportions, with hangerson of whom any party would be ashamed.

While we think that the result of this election goes to strengthen principles that must in the long run prevail everywhere, we do not imagine that it will at once snuff out the contention that has arisen. "Harmony" is not generally secured by a victory at the polls, however decisive, but the signal failure of improper devices to prevent that victory is apt to clear the moral atmosphere; and so, in this instance, we trust that henceforth the controversy will be one in which argument shall take the place of strategy, and one in which men will admit that those who differ with them in this matter are actuated by motives as honorable as their own. We see nothing to deprecate in a continuance of the controversy, but we do see...
THE IMPORTANCE OF THE CODE CONTROVERSY.

There has been a disposition in some quarters during the past year or more to frown upon all mention of the code controversy. It has been spoken of as a bore, and certain persons have been fond of saying that they were "tired of it." All such expressions must either be the shallowest of affectation, or else they must betoken an inconceivable failure to grasp the situation. We can understand that men whose energies are fully engaged with the problems that every day's life thrusts upon them should feel annoyed at petty outbreaks in a contention of this sort, at spurs that savor of strategy rather than of argument, at filibustering, and at the thrusting of side-issues before meetings called for scientific work. In all conscience, we have had enough of those exploits.

But those matters are not what we now have in mind; we refer to the main question. To assume that it is unworthy of full and serious consideration is to say that a great number of the ablest and noblest members of the profession have been giving their minds to trifles. When we see the American Medical Association resorting to questionable practices in order to protect itself against the possibility of an attempt to modify its code, we can scarcely allow that the movement against which such extraordinary defensive measures are taken is the mere whim of an inconceivable faction. When the scientific work that, in the natural order of things, would have been done at two stated meetings of so conservative a body as the New York Academy of Medicine gives way to a discussion that practically turns upon the merits of the code question, those meetings, protracted as they were, being sat out by men who, on account of age or infirmity, are seldom seen away from their own firesides after nightfall, we can hardly infer that business of no consequence is in hand. When more than six hundred of the busy physicians of this city spend four mortal hours at a stretch in the work of choosing officers for the county society, simply because the interest turns upon the candidates' affiliations with regard to this question of codes, it does seem as if they, at least, looked upon the matter as of some importance. When we find the American Surgical Association, a young and ambitious organization aiming to achieve some approach to realizing its pretensions, deliberately cut down its membership by practically ousting one of the foremost surgeons of the country—a gentleman of ripe years and of a spotless life—merely for the reason that he will not renounce his approval of the movement against the old code, we can not but suspect that the association views the movement as one it must notice.

For a man of convictions on such a question the world has respect and even admiration, no matter if he is indiscreet, pragmatical, and intolerant. It will even wink at still more unpleasant accompaniments. But for a man who is so stupid as to not recognize what is going on about him the world has no charity. Let us hear no more, then, of this inanity. Nothing but good can be the eventual outcome of the most thorough examination of the question in all its bearings, and he who affects to be bored with its serious discussion has no place in the nineteenth century.

THE ACADEMY OF MEDICINE.

The Academy is most heartily to be congratulated on the result of the recent strife over its attitude toward the two parties to the ethical controversy. It was not to be expected that a three-fourths majority would vote in favor of so radical a move as the adoption of the propositions made by the President to amend the constitution and by-laws to the extent recorded in our issue of the 6th inst. It augurs well for the future peace and usefulness of the Academy that several of the prominent members of the party that opposed the amendments applauded the graceful and conciliatory remarks with which the President bowed to the decision of the meeting of October 18th. The decisive vote by which the motion to rescind the resolutions passed last spring was therewith carried, without debate and without the vote being questioned, was an evidence of moderation on the part of those present. But the most gratifying feature observable on the occasion was the good-natured tone that pervaded the meeting. On the adjournment, it was obvious that both parties were inclined to look upon the bright side of each other's past actions, and to unite their efforts to continue the good work which the Academy has carried on for so many years.

Unless we interpret the temper of the Academy erroneously, there will now be no opposition to the admission of any proper person to fellowship, and the institution is saved from the peril that lately surrounded it. It is to be hoped that, in the annual election, to be held in January, the nominations will be made and the candidates voted for without any reference to the code controversy. We are encouraged in this hope by the absence of any apparent advantage that either party to that controversy could gain from carrying an election in the Academy.

MINOR PARAGRAPHS.

THE NEW YORK INFANT ASYLUM.

The contention is still going on as to the degree of mismanagement that has been shown in the Country Branch at Mt. Vernon, and as to who is responsible for the same. It is evident that there are serious disagreements still among the managers and the medical officers, and it is quite as obvious that such a state of things can not long continue without practically ruining the institution.

THE COLLEGES AND THE LICENSING POWER.

The Medical Society of the County of Westchester has lately taken the decided step of preparing a memorial addressed to the Legislature, praying that body to take away from the medical colleges the power to grant licences to practice, and practically to give that power to the Board of Regents of the University of the State of New York. Such action, of course, would reduce the colleges to mere teaching bodies. This would likewise be the result in case the bill drawn up by the Erie County society should become a law. From the fact that the Westchester so-
Letters to the Editor.

THE SUPPRESSION OF QUACKERY.

At the annual meeting of the Medical Society of the County of New York, held last Monday evening, an interesting and exceedingly satisfactory report was read, showing the work that had been done by the society during the year in bringing illegal practitioners before the courts and procuring their conviction for violating the law governing medical practice. It was evident that the proper officers of the society had performed their unwelcome task thoroughly, and that their legal adviser had co-operated with them most zealously and intelligently. It was stated, too, that, with very few exceptions, the judges before whom actions had been brought had taken pains to carry out the manifest intent of the law. This function of the society is not only troublesome, in that it involves considerable sacrifices on the part of individuals in the way of attendance at court, but also expensive. It is a pleasure to record that no hesitation was felt by the meeting to appropriate the sum of $3,500 for the purpose of carrying on the work for the succeeding year.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 23, 1883:

Sir William MacCormac.—On Tuesday evening Dr. Frederick S. Dennis gave a dinner at the Gramercy in honor of Sir William MacCormac and Mr. Matthew Arnold. The next day Sir William MacCormac lectured before the class at the Bellevue Hospital Medical College. On Thursday evening a reception in his honor was given by Dr. Sims and Dr. Harry Marion-Sims.

The Cholera in Egypt.—A fresh outbreak is reported from one of the suburbs of Alexandria, a village that had previously escaped the infection. This outbreak is attributed to a canal running through the village having become contaminated from a neighboring cemetery, in which persons dead of the disease had been buried.

Cremation is reported to have been made compulsory in Lisbon in times of epidemics, and every five years all bodies that have been buried are to be incinerated.

The Free Hospital for Women, Boston, is reported to have received a gift of $35,000 from Mrs. Oliver Ames.

Dr. Joseph C. Hutchinson, of Brooklyn.—The many friends of this gentleman, whose severe injury by being thrown from a carriage some weeks ago was recorded in our columns, will be glad to learn that last week he was able to walk about his grounds.

The Epidemic at Brevston, Ala.—Several additional cases have been reported since our last issue, and the disease is now announced to be yellow fever.

Tuberculosis is said to be raging with extreme severity in some parts of Germany. At Ernsleben some of the inhabitants of nearly two thirds of the houses are stated to have been attacked. Up to the 21st inst., twenty-three deaths had resulted.

Precautions Against Leprosy in San Francisco.—The "Sanitary News" states that the quarantine officer at San Francisco is quarantining every vessel arriving in port having a leper on board. The vessel is released only upon the captain's giving a bond undertaking to return such leper.

The Kentucky State Board of Health.—We learn from the "Sanitary News" that Dr. J. N. McCormack, of Bowling Green, has been appointed secretary to the board.

The Baltimore Academy of Medicine.—We learn from the "Maryland Medical Journal" that at the annual meeting held October 16th, the following-named gentlemen were elected officers: Dr. F. T. Miles, president; Dr. S. C. Chew, vice-president; Dr. B. B. Browne, secretary; Dr. E. E. Cordell, reporting secretary; Dr. G. L. Tanayt, treasurer; and Dr. W. C. Van Bibe, Dr. J. A. Steuart, and Dr. I. E. Atkinson, the executive committee.

OBITUARY NOTES.

J. Lawrence Smith, M. D., of Louisville.—The "Louisville Medical News" publishes an obituary notice of Dr. Smith, who died on the 12th inst., in his sixty-fifth year, from which we learn that he was for many years the professor of chemistry in the Medical Department of the University of Louisville, and that he was one of the few foreigners who have been admitted to membership in the French Academy. The "News" speaks warmly of Dr. Smith's personal qualities.

The New York Infant Asylum.

New York, October 23, 1883.

To the Editor of the New York Medical Journal:

Sir: We desire to make public through the columns of the Journal the following additional facts in regard to the management of the New York Infant Asylum, which have transpired since the publication of our letter in the issue of your journal for March 17, 1883.

After the annual meeting of the board in January last, Mr. Clark Bell appointed Dr. E. F. Brush attending physician to the Mt. Vernon Home for the year. No meeting of the Board of Managers was held between May 15th and September 15th, and no meeting of the Executive Committee of the board was held between the end of June and September 29th. In July last, the president, Mr. Clark Bell, acting under the authority of the board conferred upon him at the annual meeting in regard to medical matters, removed Dr. Brush from his position as physician in charge of the Country Home. During Dr. Brush's term of service he discharged the duties of his office satisfactorily, and he had the respect and confidence of the board. The president, in his annual address in January last, says: "The death-rate for children at Mt. Vernon is 8.1 per cent. [sic], and, while this is a slight increase on past years, it is really phenomenal as compared with other institutions. . . ."

* The president overlooks, unintentionally, doubtless, the fact that the death-rate at Mt. Vernon in 1881 was thirteen per cent. Vide "Annual Report" for 1881.
The Medical Report and the Report of the resident physician (Dr. Brush) at Mt. Vernon show a very gratifying exhibit as to the health of our inmates.

The annual report of the Medical Committee of the Board, Dr. Joel Foster chairman, says: "Dr. Brush has labored at Mt. Vernon with an intelligence and industry which are worthy of all praise. The material in some of his monthly reports is a valuable addition to our present knowledge concerning the rearing of infants." The chairman of the ladies' committee for the Mt. Vernon Home in her annual report says: "The Medical Report will show that the deaths have been few. To the sound, sensible treatment of cases, and sound sanitary suggestions of Dr. Brush, is greatly owing this higher rate of health and vigor." Dr. Brush's removal was made against the remonstrance of four medical members of the Board of Managers. His place was filled by the appointment of Dr. Caroline G. Marr, as resident physician.

Since early in August an epidemic of measles has prevailed at the asylum—seventy-five children have died—measles, whooping-cough, diphtheria, capillary bronchitis, croup, cholera infantum, gastritis, meningitis, pneumonia, and diarrhoea being variously assigned as the causes of death.

Between September 18th and 27th fourteen deaths took place. Upon September 29th, at a meeting of the Executive Committee of the board (called at the request of a medical member of the board), this communication was presented:

**NEW YORK, September 20, 1883.**

To the Board of Managers of the New York Infant Asylum:

Gentlemen: We all alike deplore the calamity which has befallen our Country Home at Mt. Vernon. The epidemic which began during the month of August has already desolated fifty lives, and during the past ten days fourteen deaths have occurred, which shows that the violence of the disease has not abated.

Evidently the means hitherto used are inadequate to control the disease.

In this emergency we offer our united services to the Asylum, requesting that full control of the medical and sanitary interests of the Country Home be delegated to us until the epidemic is ended.

Signed by Dr. Foster, Blakeman, Burdall, Goodridge, and Nicol.

Three of the medical members of the board were then unanimously appointed a committee, which was requested and authorized to proceed to the Mt. Vernon Home of the New York Infant Asylum, and institute such measures as they deem expedient to control and subdue the epidemic now raging there; and that they be authorized further to employ such medical assistance as may be necessary to cooperate with the physician in charge of the said Home.

Mr. Clark Bell was not present at this meeting.

Acting under this authority, the committee visited the Mt. Vernon Home and examined carefully into the condition of the institution. The result of their examination convinced them that the resident physician was incompetent for the emergency. They found that the prompt action necessary to control the epidemic could be secured better by intrusting the medical care of the Home to one head than by any co-operation. In fact, co-operation was impracticable. They therefore reported to the chairman of the Executive Committee that their authority was insufficient for the occasion. The chairman thereupon directed them to take all action they might deem necessary, and stated that they must be sustained therein. The committee then returned to the Home. The resident physician was not at the Home. And, in order to spare her feelings, it was suggested that she might have a temporary leave of absence. They placed Dr. Brush (whose former record in the Asylum entitled him to confidence) in temporary charge, and he entered at once upon the duties of the position. When the resident physician returned (two days later) she refused to recognize the power of this committee, although shown the following letter from the chairman of the Executive Committee:

**Dr. Marr, Mt. Vernon Home:**

As Dr. Brush is now in charge of the medical duties in the institution by the direction of the sub-committee of the Executive Committee, in order to prevent unpleasant and antagonistic feelings, I would kindly suggest that you allow him (Brush) to remain so until after the meeting of the Executive Committee.

Very truly yours,

(Signed by the Chairman).

While this committee was at the Home, the president of the board directed the resident, by telephone, to retain her place. The medical committee appointed by the Executive Committee then withdrew. This took place upon October 4th.

At a meeting of the Executive Committee held upon October 6th, the action taken at the meeting of September 29th, in reference to this Medical Committee, was rescinded without its chairman (who was present) being allowed to report. At this meeting Mr. Clark Bell was present.

On October 6th the coroner held an inquest upon the body of an infant who had died at the Home. From the verdict of the coroner's jury, which was rendered on October 13th, we quote the following:

It appears that in two months thirty per cent. of the children in the asylum have died. This fearful rate of mortality, in our opinion, is, the result of gross negligence upon the part of those having charge of the medical and sanitary department of the Institution, and a lack of attention of the president of the society, acting under the authority of the Board of Management, in appointing and retaining a person incompetent of performing the duty required of a physician in charge of such an Institution.

We request that the attention of the proper authorities be invited to the matter referred to, and that immediate steps be taken for the suppression of the epidemic now, and for some time past, existing at the institution, and that all legitimate means be had in respect to insuring not only the lives and health of the inmates, but also the lives of those residing in the neighboring districts. Further, we request the coroner to call the attention of the district attorney of this county to this investigation, and ask him to inquire whether the extraordinary rate of mortality above referred to is not a proper subject for criminal investigation by the Grand Jury.

The resident physician still retains her position.

It seems proper to refer to the statement which has been made in the daily papers, that the trouble in the Board of Management arose from the opposition by the medical members of the board to the employment of women physicians. Newspaper statements concerning medical matters are often incorrect, yet the newspaper is the history of the times. In the present instance we notice these assertions to deny them. We do not recognize sex, but competency, in both medicine and law. We will only say that a majority of the committee was not unfavorable to women medical management in the Asylum. As to women's aid in the management of our institution, it has often been found of the greatest service. We would state, however, that, in consequence of the course taken at the meeting in January, the Asylum lost the services of the most efficient member of the Committee on Adoptions—a lady who labored unceasingly to place the unfortunate children of the Asylum in comfortable homes, and it is not too much to believe that some of the children who were swept away by the epidemic would, but for the loss of her valuable assistance, be now in good homes. The Adoption Committee has sustained a severe loss, and one useful branch of asylum work has thereby been seriously crippled.

We close this paper not from lack of further material, but...
we believe the foregoing sufficiently explains certain events which have recently transpired in the New York Infant Asylum.

To the Editor of the New York Medical Journal:

Sir: Will you please state that I am not a member of the Medical Board of the New York Infant Asylum, and that I have never had any official connection with the institution.

Respectfully, your obedient servant,

W. M. Polk.

The New York Academy of Medicine.

To the Editor of the New York Medical Journal:

Sir: The reasons why I declined to vote on the resolutions offered by Dr. Flint, Jr., last spring, when the yeas and nays were called, are to be found in the following communication, made by me to the Academy at its meeting held October 18, 1883:

Mr. President and Fellows of the New York Academy of Medicine: Important as the business before the Academy is, the undersigned believes that, in view of the serious misrepresentations made as to his position regarding the voting on Dr. Flint, Jr.'s, resolutions, April 19, 1883,* he will be permitted, as a matter of privilege, to make a brief explanation.

When called upon to vote on said resolution, he declined to do so, and was subsequently reproached both within and without these halls for duplicity, timidity, and similar unpleasant qualities. He desires to state that his declining to vote was from an entirely different motive than any which could be based on the contents of said resolutions. He believed and stated at the time, and still believes, that "said resolutions were out of order, or at least inconsistent with those passed about a year previous and which were offered by Dr. Austin Flint, Sr.

Resolved, That the Academy hereby disavows any sympathy with the action of the State Medical Society, which has put the profession of the State, through its State and County societies, in an attitude of opposition to the medical profession of the rest of the United States.

Whereas, The New York Academy of Medicine has adopted in its by-laws, as its standard of medical ethics, the code of ethics of the American Medical Association, and

Whereas, Each newly-elected Fellow of the Academy is required to sign its constitution and by-laws, be it

Resolved, That the Committee on Admissions be and is hereby instructed to report to the Academy for election as resident Fellow no physician who is known to the committee to be in opposition to the code of ethics of the Academy, and who, as a consequence, can not consistently sign the by-laws of the Academy.

Resolved, That these instructions to the Committee on Admissions be continued in force until the American Medical Association shall have modified or repealed its code of ethics, and such modification or repeal shall have been adopted by the Academy, or until the Academy shall have modified or repealed its by-laws referring to medical ethics.

Dr. Guiley moved that reconsideration of the vote on the resolution instructing the Committee on Admissions be indefinitely postponed. Seconded and carried.

It is claimed that the passage of these resolutions was secured through a packed house, brought about through the medium of a secret circular.

On the motion of Dr. A. L. Loomis, duly seconded, these resolutions were rescinded by a large majority vote, leaving the national code intact and the qualifications for resident Fellowship as formerly required by the by-laws.

To those who have forgotten the transaction alluded to it may prove of interest to know that, according to the secretary's minutes of April 6, 1882:* "The report of delegates to the State Medical Society was then taken up, and, after some remarks, Dr. Austin Flint, Sr., moved that the report be accepted and the further consideration of the topics and objects which it contained be indefinitely postponed. Seconded and unanimously carried."

He had therefore the unpleasant alternative of either voting against resolutions which the Academy had previously sustained the spirit of, or of voting for them and repudiating the previous resolution carried by the society. Aside from this, the defect of the resolution, the one before the house, was not voted for as required by Section 5, Article XXV, of the by-laws, which requires that the yeas and nays on any question shall be taken without debate, and recorded in the minutes when called for by five Fellows present. It is a fact that the yeas and nays were not called for by five Fellows in accordance with the provision of the by-laws, and this fact can be ascertained from the minutes.

E. C. Harwood, M. D.

New York, October 18, 1883.

44 West Forty-Ninth Street.

Proceedings of Societies.

Medical Society of the County of New York.

The annual meeting was held October 22, 1883, at the Hall of the Young Men's Christian Association, the President, David Webster, M. D., in the chair.

Election of New Members.—The Comitia Minora reported favorably upon the names of eighty-one candidates for membership. A motion having been made that action upon the names of these candidates lie over until after the election of officers, the motion was voted down, and the candidates were admitted to membership. Brevet Lieutenant-Colonel Bennett A. Clements, Surgeon, United States Army, was elected an honorary member.

A Charge of Bribery.—A question was raised, whether these newly-elected members were entitled to vote in the election of officers, and it having been decided that they were so entitled, Dr. Iapone P. Ozenbanger asked if a member's vote could be challenged on the score of bribery. "Certainly," said the President; "whereupon Dr. Oberndorf was understood to say: "Then the votes of all these eighty-one gentlemen may be challenged." This incident gave rise to some commotion for a short time, but, as it was apparent that no challenge had actually been offered, the meeting proceeded to ballot for the election of officers, Dr. Henry G. Pypad, Dr. Edwin W. Ward, Dr. William T. White, and Dr. William T. Alexander having been appointed tellers. The ballotting occupied upward of two hours, at the end of which time the tellers retired to count the votes, and the business of the meeting was proceeded with.

Amendments to the By-Laws.—Due notice having been given, the following amendments were adopted:

* The report cited referred to the New York State code, and, as it was not in accord with the code of the Academy, it was thought best to bury it, which was done with the full assent of all Fellows present; but, a year or more subsequent, it was in effect unwisely and unlawfully surrendered, for what purpose, can not be appreciated, but its effect was to cause, what Dr. Flint, Sr.'s, motion was intended to avert, bitter feelings and unpleasant commotion among the Fellows. It is now hoped that, as the Academy is again restored to its original basis, scientific work will be renewed, and peace and harmony will forever prevail within its walls.
**PROCEEDINGS OF SOCIETIES.**

**Article 1, Chapter XII, shall be amended as follows:** "When any physician or surgeon applies for admission into this society, he or she shall place his or her medical diploma with the blanks, hereunto appended, properly filled out and signed, in the hands of the secretary, who shall lay them before the Comitia Minor, whose duty it shall be to examine the same, and, if it approve thereof, shall grant him or her a certificate of membership, subject to the approval of the society.

1. **Blank for Application.**

   To the Secretary: The undersigned, residing at ________ a graduate of ________ in the year 18__, and registered at the County Clerk’s Office, applies for membership in the **Medical Society of the County of New York**, and furnishes the accompanying memoranda for permanent record:

   Name in full (including middle).
   Born (insert town, county, State, and date, giving month, day of month, and year).
   Attended school (insert names of schools, teachers, and locality).
   Graduated in arts or sciences (insert name of college and year of graduation. If not graduated, how long in college?).
   Commenced the study of medicine in the office of, or with (here insert name of medical preceptor and his residence).
   Attended lectures at (insert name of college and date of graduation).
   Was a resident in hospital (insert name of hospital and length of service. If time was spent abroad in the study of medicine, mention the locality and length of time).
   Commenced the practice of medicine (insert date and locality).
   Subsequently practiced at (insert subsequent place or places of residence).
   Reside at present at (insert residence).
   Have held (insert places of honor or trust held and resigned; also those now held; also membership in societies; also prizes received; also dispensary or college appointments filled).
   Served in army or navy (state duration of service, with dates; also field of labor; also rank held).
   Subject of thesis.
   Insert titles of any publications.
   Elected a member.

New York ________ 18__ (Signature).

2. **Blank for Recommendation.**

   To the Secretary: The undersigned being personally acquainted with Dr. ________, of ________, a graduate of ________, in the year 18__, recommends ________ for membership in the **Medical Society of the County of New York**.

Chapter XVII shall read as follows: "No member of this society shall assume any sectarian designation indicating that his practice is based on any special doctrine or dogma, or specified method of treatment."

Chapter XVII shall become Chapter XVIII.

**Scarlet Fever in Horses.**—Dr. John C. Peters gave a short verbal résumé of the report of a committee appointed to investigate this subject. [The substance of what Dr. Peters said has already been published.]

**Dr. Oberndorfer’s Charge of Bribery.**—Dr. F. R. Sturgis called upon Dr. Oberndorfer to explain what he had meant when he referred to bribery in the early part of the evening; and added that such remarks amounted to a very serious matter.

**Dr. Oberndorfer** explained that he had meant to assert that bribery had been attempted with a member of the profession, whom he would not now name, by a representative of one of the parties in the ethical controversy—he would not say which one—to induce the person in question to become a member of the society, the object being to gain his vote in the election now in progress. He was ready to substantiate his assertions before the proper committee, but not now. He had stated in regard to the eighty-one newly elected members that their votes might be challenged, but he had not intended that that remark should have any connection with what he said about bribery.

On motion of Dr. Sturgis, the matter was referred to the Comitia Minor.

**The Election of Officers.**—Dr. Piffard, on behalf of the tellers, reported that the whole number of ballots cast was 599, several of which were blanks. The vote stood as follows [the names of the old-code candidates are printed in Roman, and those of the new-code candidates in italics]:

- **For President:** T. Galliard Thomas, 229; S. Oakley Van der Poel, 375 (Dr. Van der Poel’s majority, 155).
- **For Vice-President:** Charles A. Leale, 215; Andrew H. Smith, 380 (Dr. Smith’s majority, 155).
- **For Secretary:** E. A. Judson, 210; Wesley M. Carpenter, 385 (Dr. Carpenter’s majority, 175).
- **For Assistant Secretary:** P. Bryneberg Porter, 215; Charles H. Averey, 380 (Dr. Avery’s majority, 165).

- **For Treasurer:** Henry D. Nicoll, 208; Orlando B. Douglas, 384 (Dr. Douglas’s majority, 176).
- **For Censors:** Charles McBurney, 224; Frederic R. Sturgis, 385; Richard H. Derby, 268; David Webster, 383; Charles S. Wood, 210; Daniel Lewis, 377; Charles Hitchcock, 215; R. R. S. Drake, 373; Thomas H. Burchard, 215; Joseph W. Howe, 378. (Dr. Sturgis’s majority, 161; Dr. Webster’s, 175; Dr. Lewis’s, 167; Dr. Drake’s, 160; Dr. Howe’s 163.)

**NEW YORK MEDICAL AND SURGICAL SOCIETY.**

A stated meeting was held May 26, 1883, Dr. A. C. Post Chairman.

**Internal Cancer with Obsolete Symptoms.**—Dr. A. B. Ball related a case as follows: A woman, forty-five years of age, past the menopause, began, in the early part of the summer of 1882, to fail in health without particular symptoms except those of general weakness. There was slight diarrhoea, from two to four passages a day, from July until some time in January, after which time it ceased. The pulse was 120 from July until January, and the patient complained of palpitation of the heart. There was also projection of the eyes, and exophthalmic goitre without enlargement of the thyroid gland was suspected, but the relatives said that the projection of the eyes was normal. The patient was seen in consultation by Dr. Du Bois and Dr. Draper. A diagnosis was not reached. In January the pulse fell to about 90, the diarrhoea ceased, there were no symptoms of renal disease, there was no elevation of the temperature, there was no acute pain. In March there was evidence of slight accumulation of fluid in the abdominal cavity, amounting, three or four days before death, perhaps to several quarts. Palpation revealed a hard mass beneath the fluid, which was believed to be cancer of the left ovary. The patient went to the country for a short time, and soon after her return to the city a marked diminution in the size of the abdomen took place, accompanied by the passage of a large quantity of urine. Four days later she died. Dr. Ball had not seen the patient from the time she went to the country until her death. The post-mortem was made by Dr. Ferguson, who found a large mass in the left
PHILADELPHIA COUNTY MEDICAL SOCIETY.
Meeting of September 29, 1883.

The Duty of the Hour: Being an Examination of the Relation of the Medical Profession to the General Use of Alcoholic Liquors.—Dr. Henry Leffmann read the following paper:

In his work on the descent of man, Mr. Charles Darwin, of blessed memory, remarks that he made, in the course of his studies, a large collection of the definitions which have been offered as expressing the distinctions between man and the lower animals. The primary object of this collection was to show the insufficiency of such definitions, but, unfortunately, the learned author abandoned his plan and the list was never published. I have always regretted this, because I was anxious to see if any one had been bold enough to sacrifice the honor of the race to its independence; in other words, to define the human being as the only animal in which natural passions are subdued and unnatural appetites developed. Though it may be a permissible view of human nature, yet we cannot avoid the conclusion that the definition is substantially correct. The history of races and nations presents us invariably with a picture of unbridled passions, the fierceness of which is but slowly and uncertainly assuaged by civilization, for, in the modern as well as the ancient world, it is in the centers of intellectual development that the greatest license has been seen. Legislators, both of the civil and ecclesiastical orders, have wrestled with these problems, and, in some forms of excess, have tried every expedient, from the most desperate repressions to the most indulgent remonstrance, but with only partial advantage. Among the races which appear to be characteristic of man under every climate and social condition is the use of alcoholic liquor; and although the evils of this indulgence have been vividly presented to every one, yet a determined effort to obliterate the habit belongs only to our own time.

In that almost exhaustive treatise on moral and religious polity, the Jewish and Christian Scriptures, we notice that the duty of total abstinence has not been hectically either among Hebrews, although the daily duties of life were regulated with microscopic minuteness, nor among the leaders of the new dispensation, although they founded a most extended system of asceticism and self-denial. We are concerned, however, with the present, not with the past. Around us is a social system of great complexity. Though progress is slow, yet we need have no fear of its general direction. Each year marks too slight a movement to permit us to distinguish the result, but each century gives us a definitely recognizable advance, and shows clearly the tendency of the race to a higher and purer life. It is the text of my discourse to-night that the basis of this higher morality is self-restraint, and the basis of self-restraint is the influence of example. In the consideration of total abstinence, and the relation of the medical profession to its encouragement, we must clearly distinguish between the use of alcohol as a beverage and as medicine.

With the question of its therapeutic indications and contra-indications we have absolutely nothing to do in this paper. As to the method and form of its clinical use, however, as will be shown later, very important questions arise.

I think I may safely assume that the use of alcohol is not necessary to the maintenance of ordinary health. Its physiological effects have been extensively studied, and concordant results have not always been obtained. I need not stop to reconcile these differences, for the greater portion of the published results is not germane to my subject, nor will it be necessary to devote time to the presentation of statistics. One authority will be sufficient, because it is an authority in whom opportunities of observation and experiment are combined with
sound common sense and accurate logic. Without desiring to slight the labors of other workers, I think we find in Parker's "Hygiene" the whole subject of alcohol so thoroughly discussed as to render other authority superfluous. In this work it is established beyond question that the use of alcohol is not beneficial, that it does not increase the power of the system to resist extremes of heat, cold, or fatigue, and that, even in special cases in which stimulants appear to be needed to maintain the resisting powers, other substances may advantageously be used. It is certainly surprising to read that one of the most common opinions, I would rather say superstitions, about alcohol—that it assists the body in resisting cold—is without foundation. Scarcely any of the minor causes of drinking are more general than this, yet the unanimous testimony of those who have been in charge of polar expeditions is against its beneficial action in such vicissitudes, and some of these leaders have, after their first experiences, declared that they would not, on any subsequent voyage, take any person addicted to the use of stimulants. As regards the general effect of the continual use of alcohol on persons in ordinary health, I can not do better than quote briefly from papers read by well-known clinicians before this society two years ago. Dr. Wood says: "Although I hold that the habitual use of alcohol is to well-fed persons not only unnecessary but positively harmful, it seems to me that in many cases of disease, and in those periods of life when by reason of age the body waxes weak, alcohol is found of great value. Under sixty years of age the daily employment of wine may for most persons be very well discounted. . . . It is notorious that in America almost every one in reasonable health consumes much more food than the system needs, so that any alcohol taken is added to that which is already in excess." Dr. Pepper holds that the quantity permissible is very small, not more than one ounce and a half of absolute alcohol in twenty-four hours, taken much diluted, and only at meals. A very large number of persons, either from susceptible stomach or a gouty distillation, can not safely take alcohol at all. Dr. Bartholow says: "As a stomachic tonic, alcohol is effective only in the case of those not habituated to its use. . . . That in time a catarhhal state of the mucous membrane is produced and a pathological secretion obtained, shows the impropriety of the long-continued use of alcohol as a stomachic tonic." Finally, although relating to the therapeutical use of alcohol, I can not avoid quoting some forcible and logical remarks made by Dr. Woodbury in a discussion on the treatment of pulmonary consumption. "Nothing in clinical medicine is more certain than that the continual use of alcohol, in even moderate doses, stimulates the development of connective tissue all over the body; nothing in pathology more evident than the fact that alcohol is a prolific source of pulmonary disease; nothing in toxicology better established than the observation of the action exerted by alcohol upon the respiratory center. For this reason it is especially dangerous in pulmonary consumption."

It is, unfortunately, too true that no quotations from authority or orations of statistics are needed to show the moral and physical injury done by alcohol. Directly and indirectly, it is a prime factor in the promotion of disease and crime; and, when we reflect upon the thousands of desolated homes and ruined prospects for which this agent is annually responsible, we can not wonder at the sentiment which is slowly but surely developing in the community against all phases of industry or trade which have for their object the furtherance of the use of alcohol, nor can we doubt that to the success of the work of moral regeneration of our race the obliteration of these industries is essential. A powerful assistance in securing and maintaining sobriety would be to destroy the superstitions respect in which the various beverages are held. Non-medical persons are generally aware that physicians attribute particular values to particular liquors. In my own experience I have found very few persons who are willing to admit that they use liquor merely because they like it. They generally find some other reason—the necessities of the system, the advice of some physician, either to themselves or to some friend. One person uses beer because it is a tonic; another, because of its nutritious value, and so on—every reason but the real one, because they like it. Not a little of this popularity of liquor is due to the glamour of sentiment which attaches to it. Even the austere psalmist, who, with the exception of a single sin, "did that which is right in the sight of the Lord," has praised the "wine that maketh glad the heart of man." And for ages poets and prose writers have extolled the qualities of stimulating beverages and the romance of their manufacture. In our time, however, these sentimental features are but imaginary. Nothing in the present methods of producing liquors is of a character to make us repel them as types of poetic or con-trivial relations. The wine that stands on our tables no longer shows in its ruddy color the rainbow tints—

"Caught where the morning sunbeams, stooping low, Have kissed Grenada's plain."

Nor does its aroma repeat

"The dainty perfumes of the East
That Horace used to praise."

But the suggestions that are now called up by those who know the facts are the suggestions of the fourth floor of a Front Street warehouse, where rectified spirit, animal charcoal, glycerin, saponified cotton-seed oil, aniline red, burnt sugar, et hoc genus omne, are being mixed together and transferred to casks and bottles ornamented by lying labels. The foaming tankard of malt liquor no longer suggests the

"— house where unt-brown draughts inspire,"

but the images now appropriate are those of blasted workmen, aloe, quassia, and the hop substitutes, salicylic and boric acid, baking soda, gum for preserving froth, and beer-pumps for producing it. In short, no romance belongs to our alcoholic beverages. They are the products of influences allied with the lowest levels of mercenary honor, and their touch is corrupting.

In an article read before this society two years ago, I put forward the view, that when alcohol is to be used by physicians it should be used as such, and not in the form of special manufacturers. I can not express myself better than by my words on this occasion, as follows:

"We know that liquors prepared by strictly natural methods are not constant in composition; we know that under the exigencies of trade additional conditions of variations are produced, and even complete substitution brought about. I have for some time thought that the best way to secure entire constancy in the therapeutic use of alcohol would be to have the preparations made up by regular prescription, or by printed formulae in the Pharmacopoeia. The substances which exist in wine, beer, or brandy are in accidental mixture; some are useful, others useless. Why should we not have the useful articles properly com-

bined by competent hands and the useless omitted! . . . And the physician, instead of ordering a special wine, will simply prescribe such preparations as may be necessary of alcohol, water, flavoring ethers, and astringent or bitter principles." These prescriptions, like those containing other powerful ingredients, should be renewable only at the instance of the physician.

I have lately learned with much pleasure that Dr. A. W. Miller, of this city, a gentleman well known to most of the members of the society as an experienced pharmacist, is about to publish a paper advocating a similar view. Dr. Miller, indeed, expressed such opinion publicly several years ago, although I was not aware of it then. His large experience in the manufacture of flavoring, coloring, and other materials used in liquor imitation, gives him the right to speak with authority, and I find, by my conversation with him, that we are entirely in accord. In his paper he intends to call attention to the fact which I would not have time to consider, that, in wines and brandies, astringent articles are sold at high prices, and thus the practice of ordering such articles exposes patient to both deception and robbery. Not the least of the injuries which are done to the community by the laxity of physicians in reference to the use of liquors is the encouragement which is thus given to the sale of quack medicines under the guise of bitters and tonics. No greater fraud is put upon the public than the preparations which are advertised under these names. They are alcoholic beverages in their most dangerous and insidious form. I have seen this week examined one of the most extensively advertised of the lot—Warner's Safe Tonic—and I find it to contain a considerable amount of alcohol, in association with some vile combination of syrup and bitter extract. When it is remembered that the medicinal stuff is bought at a price much above its value, and is used mostly by persons already somewhat out of health, we must see that the harm done is incalculable. Yet the popularity of these articles is largely due to the fact that they meet what most people believe to be a necessity in disease, an alcoholic tonic. During the last few years several eminent physicians and chemists, in this country and abroad, have gone almost into spasms over a knowledge of such adulterations as the use of alum in baking powders, glucose in candy, and oleomargarine in butter—all trifling and non-injurious substitutions; but we hear very little about the far more dangerous preparations of the class just alluded to. The most striking evidence of the profoundly misguided condition of the public mind on these topics was well shown lately in New York, when the officers of the Business Men's Moderation Society gravely condemned the use of the harmless glucose in beer, and then gave, inferentially at least, certificates of wholesomeness to beer containing between four and five per cent. of alcohol. The quack medicine mentioned above has with each bottle the official certificate of the professor of chemistry of the University of Rochester, stating that the preparation is free from deleterious ingredients. I feel sure that statements like this could not be made if medical authorities were true to their own knowledge on these questions.

It is in view of the points which I have here enumerated that I feel obliged to lay before this society, and, through its published proceedings, before the world, the accusation that the medical profession is responsible for a very large portion of the misery which alcoholic beverages produce, and I declare that the time has now come when a stand should be taken in favor of abstinence. I believe that it is established by the citations I have given that alcohol is not needed by healthy persons. I know that many non-medical persons use liquor because of the general approval of it by the medical profession, and I think it can be demonstrated that, although alcohol itself is a substance of great value, alcoholic beverages are entirely unnecessary. Of late years, although physicians have assumed the right to speak broadly upon many questions affecting public health and public morals, they have been singularly conservative as regards the evil of moderate drinking. Yet it seems to me that sewer construction, registry laws, quinine pills, river pollution, ethical innovations, etc., on which topics so much energy has been expended recently, do not approach in magnitude the reform which is here urged.

The pollution of a river water by organic matter before it reaches a city reservoir is rarely so serious in its effects as the pollution of it by alcohol after it leaves the hydrants, and the dangers of Rye Beach, of which we have heard so much, are trifling compared with the dangers of rye whisky, or what is labeled as such.

The learned professions are potent influences in moral reform, and for many centuries law and divinity have exercised much more control over the race than has medical authority. This relation is now rapidly changing. The questions of civilization are regarded as practical problems, largely medical in character, and the direction of education is passing into the control of the scientist and physician. Both the lawyer and divine have recognized alcohol as a foe to public and private virtue, for courts now frequently regard intoxication as an aggravation rather than as an excuse for crime, and the almost unanimous temper of churchmen is against any form of indulgence in stimulants; even the time-honored employment of wine in communion is not sufficient to maintain its use, and unfermented wine is now a familiar article of commerce. Let us, then, begin at once to discharge our duties, and ally ourselves openly with the laity, who, though lacking in scientific knowledge, have the good of the community at heart. Let us recognize that, while many evils claim our attention, the importance of a firm stand in favor of total abstinence is urgent, and is indeed the "duty of the hour."

The President stated that the points presented for discussion were: 1. That the use of alcohol in any form and in any amount by persons in ordinary health was deleterious. 2. That the medical profession, by its lax attitude on this question, was responsible for much of the prevailing abuse of alcoholic liquors. 3. That if alcohol was to be used at all, it should be given as such, and the prescription should be made non-renewable, as with other powerful medicines.

Dr. J. T. Eskinder, in opening the discussion by request of the President, said: I like the practical and novel way in which the subject has been treated. It will attract attention, and, I hope, serve to make the members of this society, and of the medical profession in general, consider their own responsibility for the abuse of alcohol. One of the conclusions at which the writer of the paper has arrived is, "That the use of alcohol, in any form and in any quantity, by persons in ordinary health, is deleterious." This is a broad and sweeping statement, and, while in the main it is correct, circumstances may arise when alcohol may be administered to persons in health with benefit. Dr. Percy's experiments showed that the free use of alcohol tends to prevent the solidiifiability of fibrin, and thus renders wounds difficult to heal; and those of Vierordt and Front, that less carbonic acid is given off in the exhalations by the breath under similar conditions. Borchartt first pointed out that alcohol darkens arterial blood. These results were obtained by experimenting upon subjects whose stomachs had been overcharged with alcohol, or into whose veins the spirit had been directly injected. They show the poisonous effects of alcohol, and, reasoning from these, it by no means follows that the administration of small quantities well diluted is injurious as to health. But observations are not wanting to prove the evil effects of alcohol on healthy persons when taken in small quanti-
ties for a considerable length of time. Professor W. B. Carpenter, a strong advocate of temperance, in his admirable prize essay on the "Use of Alcoholic Liquors in Health and Disease," after describing the salutary effects of alcohol on mind and body, when taken in small quantities several times daily for a length of time, frankly admits that its temporary administration to persons in health, on certain extraordinary occasions, is attended with decided benefit. Professor Miller, of Glasgow, in an excellent review of the subject, entitled "Alcohol: Its Place and Power," arrives at conclusions almost identical with those reached by Professor Carpenter.

I am satisfied that persons in health, under ordinary circumstances, do not need an alcoholic stimulus, and that, if its administration is attended by no good results, evil only follows the use of alcohol at such times; but, on the other hand, I am convinced that circumstances do arise when, if alcohol is properly administered to persons in health, its good effects far outweigh its evil; and that there are conditions, short of what we are accustomed to call disease, which are improved by the temporary and judicious employment of alcohol. Bodily and mental labor that can not be endured without resorting to artificial stimulants had better be left off; but times come in the history of many persons when they are not their own task-masters. A great deal may depend upon a few hours' work. Tea and coffee may not be sufficient stimuli, and a little alcohol taken at these times will allow of an extra strain being made upon the system. The use of alcohol must not be often repeated for the purpose of increasing the power of endurance. It must be remembered that a stimulus in these cases acts the part of the spur to the tired horse. It probably does not directly add force to the individual, but it enables him to call more upon his latent powers, and, of course, the exhaustion which follows is all the more prolonged by the reason of the extra strain upon the vital forces, made possible by the use of alcohol. Again, the appetites of some persons have been rendered capricious by the process of codding, and those of others lessened, and the power of digestion weakened by worry and over-mental exertion, so that the simplest articles of food cannot be digested properly. To such the administration of a little wine, with a bitter tonic, before meals, for a week or two, and subsequently a bitter tonic given before meals, and wine during or immediately after the ingestion of food, is followed by admirable results. In all these cases the use of alcohol must be cautious and temporary, and not allowed to be continued longer than is absolutely necessary. I agree with the statement made by the reader of the paper to-night, that below sixty years of age a person is generally not benefited by the use of alcohol in health. I know, indeed, of a case in which it did not become necessary to resort to it before the twelfth year.

In regard to the use of alcohol in phthisis, to which a casual reference has been made, I have very strong convictions of its value when properly employed. In this disease, when pulse is rapid and temperature considerably elevated, alcohol is contraindicated, but in the more chronic cases, when respiration is difficult, and pulse and temperature nearly normal, its beneficial effects in prolonging life are evident to every one who has given it a fair trial. Professor Flint speaks in the highest terms of alcohol in phthisis. As a preventive of phthisis, alcoholic stimulants have their place and power. It is well known that in the same family several children, whose parents have suffered from phthisis, may die from this disease at about the same age. For these persons, if alcohol is occasionally employed judiciously, whenever vital force falls below its normal in them, I have no doubt that in many instances the fatal disease might be prevented.

To the second proposition I may say that I do not know of any case in which the use of alcohol in disease, under direction of a physician, gave rise to drunkenness. Some time ago Dr. Hamilton, in a discussion before this society, mentioned a case in which a patient became a drunkard in consequence of the use of alcohol in typhoid fever, but it appeared on further inquiry that the man was an habitual drinker before the disease occurred. Lax prescribing, however, may easily become a serious error. It is important that, if alcohol is ordered, the quantity, form and time of taking should be indicated. It should be taken only at meals. This periodic and formal use of it will make the patient willing to stop when required. I admit that, if we consider that alcohol is injurious in health, we must regard its use in social gatherings, and especially in those composed of medical men, as wrong.

In reference to the last points, I can not speak from experience. If the adulteration is as extensive as pointed out in the paper, then the author's view, that alcohol should be used as mentioned, is correct. I, however, doubt if we can make, extemporaneously, mixtures which will take the place of natural liquors.

Dr. Mills said: I would not wish to be regarded as an advocate of anything else but temperance in the best sense of the word, but the question of the influence of the moderate use of alcohol upon intellectuality and the longevity of intellectual workers is one of considerable interest, from what might be termed a biographical point of view. During the International Medical Congress of 1876 one of the English delegates expressed the opinion, in words which I do not exactly recall, that the intellectual productions of men who did not use alcohol at all were not of a character to indicate the value of abstinence. Many distinguished men who have lived to a comparatively advanced age—the English lord chancellors, German thinkers, and well-known American statesmen, for instance—used alcohol in moderation throughout their lives. I simply introduce this point for discussion. About the evils of the abuse of alcohol no doubt can exist.

Dr. Wood: I consider the first proposition advanced by the author of the paper to be untrue; it is entirely too sweeping. To say alcohol is deleterious in any form and in any quantity in health is to say that one would be injured by simply snuffing a bottle of whisky. I am fully convinced that we do not need alcohol in health, but indulgence in it moderately, on occasions, is probably no more hurtful than over-eating. I have seen, at social gatherings, total abstainers, while standing apart from the general company and congratulating themselves upon their superior virtue in not indulging in stimulants, gorge themselves beyond repletion with the food set before them, much to their stomach's distress. The moral question involved is the old one of use and abuse—whether I must forego the use of a thing because some one else abuses it. Are we to abstain from a certain amount of pleasurable indulgence because of the example which that indulgence offers to others? I do not believe in attempting to force total abstinence, because I do not believe that the movement will accomplish the desired result. Not long ago I was traveling in Kansas, and I met a prominent prohibitionist, a member of the Central Committee of the State, whom I questioned about the success of the prohibition movement, asking, inter alia, if they had destroyed the grape industry, as the law directed, in the wine-making districts. He replied that they did not expect to do this in those places. Here was an admission of the weakness of the cause, for where the manufacture and use of wine were now most active was the least hope of abolishing it. In the same car was a traveling salesman on the verge of delirium tremens, and I asked him as to the effect of the liquor laws in Kansas. He replied: "I can get a drink of whisky anywhere in Kansas for fifteen cents."
The Scandinavian method of dealing with the temperance question seems to me more practicable. In Sweden and Norway the country is divided into districts, in each one of which only one tavern is allowed. The licenses are sold at public auction. The temperance people have combined and bought up the licenses. They are obliged to open the tavern, but they can adopt such regulations as will prevent the excessive use of alcohol by those who frequent the place, and also employ all moral means to persuade men not to drink at all. I do not think that the adulterations of liquor are as harmful as has been stated by the lecturer. Liquors and wine are artificial products always. I think that good liquors can be easily obtained. I do not agree with the proposition that medical men are responsible for the habit of drinking to excess; on the contrary, the example and teaching of the medical profession have done much to diminish the evils of intemperance.

Dr. O'Hara: In reference to the remarks of the last speaker, let me read the following from Richardson ("Induced Diseases of Modern Life," page 292): "Speaking honestly, I can not, by any arguments yet presented to me, admit the alcoholis by any sign that should distinguish them from other chemical substances of the paralyzing narcotic class." If this view be correct, we can have no doubt that alcohol is injurious in health, and that it does not serve as food. We are too much under the ideas of Liebig in this matter. For my part, I can not see that the total abstinence movement is a failure, or that the views advanced in the paper are erroneous. They are the views which have been advocated by high authority, in the International Medical Congress in 1874, and other scientific bodies, for instance. The medical profession may be responsible indirectly for much of the excessive drinking, through the idea, scattered, but now passing away, that it was food. I have myself learned by experience the evils of too much confidence in alcohol, when I thought it food, and now watch it closely as a medicine. As to the cases narrated by Dr. Eskridge, they can not be regarded as cases of healthy persons, and the use of alcohol in treatment of them is a question of therapeutics, not of hygiene. Medical men may certainly accomplish a good deal by the teaching influence of example. I recall an instance in which brandy was used for dyspepsia; the patient, it is true, got rid of the dyspepsia, but he complained frequently until the day of his death, which was superinduced by liquor, that he made a bad swap, and would rather have held on to his dyspepsia.

The conclusions of Dr. Hunt's paper were adopted by the International Medical Congress, 1874, and ordered to be transmitted to the National Temperance Society, the Women's National Christian Temperance Union, and the Friends' Temperance Union of New York. They were: 1. Alcohol is not shown to have a definite food value by any of the methods of chemical analysis or physiological investigation. 2. Its use as a medicine is chiefly that of a cardiac stimulant, and often admits of substitution. 3. As a medicine, it is not well fitted for self-prescription by the laity, and the medical profession is not accountable for such administration or for the enormous evils arising therefrom. 4. The purity of alcoholic liquors is, in general, not so well assured as that of articles used for medicines should be. The various mixtures, when used as medicines, should have a definite and known composition, and should not be interchanged promiscuously.

Dr. Tyson: This question is one very difficult to discuss; both parties are apt to go to extremes. Dr. O'Hara's remarks are a case in point, for the injurious effects to which he alludes are the effects of the use of alcohol in excess and not in moderation. It must have been the experience of all practicing physicians to see many cases which are benefited by the moderate use of alcohol, especially at meals, while in many aged per-sons its use is very appropriate, and even necessary. I am not prepared to deny altogether the correctness of the second proposition offered in the paper. I think there may be some ground for it, yet I do not know a single case in which the recommendation of the use of alcohol in disease has resulted in establishing a habit of drinking. I recall a case in which a gentleman was advised by a non-medical friend to use whisky for dyspepsia. It was tried, and, finding good results from it, he continued using it in small amounts daily; the use was kept up until one day the patient found the bottle empty. He missed his usual dose so greatly that he was forced to realize that he had been drinking, and never used the liquor again. It may be laid down as a rule that it is not safe for physicians to advise the regular use of alcohol for dyspepsia; it may lead to an habitual use of stimulants. As to the third point, I think that, in view of the fact that it is still possible to get pure wines, especially if we are satisfied with domestic wines, the flavor and other properties which made them more acceptable to the patient justified their continued use; but I, for one, am willing to try the effect of pure alcohol properly diluted in cases where alcohol only is indicated.

Dr. Hamilton: Moderate drinking, it must be remembered, is very often the road to immediate drinking, and therefore the physician, whose influence in this connection is paramount, should sedulously avoid the too frequent and too liberal use of liquor, especially in young subjects. In the low forms of fever, or in chronic, wasting disease, such, for instance, as pulmonary consumption, to which alcohol has been made, it is often of great advantage, and in the latter disease, where expectoration is profuse, but unaccompanied with much fever or difficulty in breathing, it may prolong life for an indefinite period. The custom of drinking in the wealthy and fashionable circles may still be said to prevail with tyrannic power, and in ordinary social reunions the same practice is common. The influence of wealth and fashion is dominant, and until some amelioration in this connection is manifest, no general temperance reformation need be looked for in the people at large. The allusion to the adulteration of wines and stronger liquors was deservedly made, but it occurs, doubtless, much more frequently in regard to the finer and more costly than to the cheaper liquors, and the perfection to which this adulteration has attained is simply notorious.

Dr. James C. Wilson: I am much pleased to see this subject before the society. It is a subject which ought to be agitated, because the agitation will bring out the truth. I think that the propositions rather overstate the case, and somewhat weaken the points advanced. Independently of law, church influence, and local politics, a widespread popular sentiment is developing in favor of temperance, but not of total abstinence. A feeling against excessive indulgence is growing steadily in the community. It is now considered "bad form" to drink at social gatherings, and young men especially are much more restricted than formerly. The three-bottle men of earlier days are now unknown. It is, however, going to an extreme to put the proposition that the use of alcohol, in any form and to any extent, is deleterious. Many persons can use alcohol in moderation, and derive comfort from it without injury. I do not agree with the second proposition. Respectable medical men are not in their attitude on this question, but are accustomed to caution their patients in regard to the dangers of the use of alcohol. Most of them direct the amount to be taken, and fix a time for discontinuing the use, just as they do with other powerful drugs. As regards the suggestion to use alcohol alone, it appears to be open to some objections. It is not possible to imitate the different wines. No formula of the Pharmacopoeia or prescription could produce the perfect mixture which we see in natural wines, which are often so specifically beneficial.

Dr. Frank Woodbury: I have been much interested
while listening to the paper, and, in the main, sympathize with its teachings. I think that the propositions submitted for consideration were purposely framed so as to excite discussion, since they are not logical deductions from the paper, and indeed have not been presented as such. The alcohol question is a complex one; it is a great social and moral problem, as well as a scientific and medical one. The subject as presented this evening has at least three aspects: the use of alcohol in any quantity in health—this is a physiological question; its employment by physicians—a medical question; and the right of physicians to prescribe it—which is a moral question. This moral question is really the principal one of the paper, as is shown by its title, "The Duty of the Hour." With regard to the question as to its injurious effect when used in health in any quantity, I would ask, first, what is meant by a state of health? If a physiological definition is accepted, then no person living under the artificial conditions of civilization can be in a state of perfect health. Ordinary health is merely an approximation toward physiological health; and if the utility of alcohol is acknowledged in the condition of disease—which is merely any departure from the healthy standard—then the first proposition is answered by the lecturer himself in the negative. Then, again, concerning the use of alcohol "in any quantity," I think it worth while to recall the fact that not only is it without injurious effect in very small doses, but that in reality the organism cannot escape from imbibing alcohol; it is omnipresent; it is in fresh bread and in ripe fruits, and even traces have been found in the air we breathe, provided there exist a certain amount of organic matter and the conditions of temperature and moisture necessary to fermentation. Even in the muscular tissue and urine of total abstainers a substance is present chemically indistinguishable from alcohol. In large doses every one admits that it is capable of destroying life by its own properties when taken into the system, and it is therefore a poison. Its use in much smaller doses, it must be admitted, may not prove incompatible with the enjoyment of long life and ordinary health; but in many cases its constant use directly induces disease and tends to shorten life. The fact that a substance is a poison, however, is not sufficient in itself to forbid its use in disease, provided that it be given in accordance with the teachings of science and experience. The physician with the longest experience of any present has just expressed his deliberate opinion that it is useful in low conditions of vitality and in slow convalescence.

With regard to the right of the physician to prescribe alcoholic liquors, the moral aspect of the subject, I hesitate to express an opinion, for fear of being misunderstood. I would suggest, at the outset, that in reality the treatment is not so entirely under the control of the physician as is implied by the question. Is it not the fact that it is the patient who employs the medical attendant, and if he is not treated in accordance with his ideas he becomes dissatisfied, loss confidence in his physician and engages another? A rough illustration may be given: When a Chinaman falls sick, he, as a rule, will, if possible, secure the services of the kind of physician that his parents and friends approve of. A sick Indian in the same way prefers the treatment of his medicine man to that of the most scientific post physician. Is it not also true that, in more cultivated communities, the physician who is called upon in the hour of sickness is the one whose thoughts and prejudices best agree with those of his patients? Patients certainly should not be allowed to dictate in the details of treatment, but their unrelinquished right to approve or reject the general plan of treatment can not be disputed. It may seem like a humiliating admission, but it is true that, in a community where the taverns far exceed the bakeries, total abstinence physicians will have more opponents than clients.

I hope that nothing that I have said will convey the impression that I approve of the use of alcoholic liquors in disease, given merely with a view to gratify the patient; if ordered at all, they should be given to obtain the physiological action of ephyl alcohol, which, on account of variation of strength and adulteration in ordinary liquors, may be best given in the form of dilute alcohol in order to secure both purity and exact dosage. This, I have learned, has been largely employed in Bellevue Hospital, where it was introduced by Dr. Gillette; by its use the medical effects of the drug are obtained, and the danger of encouraging the use of ordinary liquors is to a large extent obviated. In conclusion, I wish to express the opinion that the second proposition should be reversed, and it should read: "Physicians deserve great credit for incalculating more correct and scientific ideas with regard to the use of alcoholic liquors by the community." The great advance in the cause of temperance, in my opinion, is very largely due to the teachings of certain prominent physicians and the precepts and example of the great body of the profession.

Dr. LIEFFMANN, in closing the discussion, said: I am dissatisfied with the direction the debate has taken, for too much time has been given to the discussion of the value of alcohol as a remedy, a point which I expressly excluded. While the propositions which I laid down are my convictions, and I believe they will all be ultimately recognized as true, yet I purposely worded them in an extreme form to make the debate more definite. No one, however, is justified in giving to the first proposition the trained meaning that Dr. Wood put upon it—namely, that snuffling a bottle of whisky would be held as injurious. The language should be judged according to its intention. The remark quoted by Dr. Mills, in regard to the literary abilities of total abstainers, is also unworthy of the dignity of the question, and is not argument. Dr. Woodbury's suggestion, that alcohol must be used because patients expect its use, is surely not the true principle of medical practice. Patients are not to be the judge of anything in treatment. The success of homeopathy and kindred delusions is largely due to the erroneous and absurd view that patients may elect the system of medicine on which they are to be treated. Neither can one regard the fact of the occasional existence of alcohol or alcohol-like bodies in organic matter, in urine or in muscular tissue, or in fresh bread, which latter I doubt very much, as any argument for its use in health as a beverage. Several of the speakers have apparently regarded the paper as declaring the adulteration of liquors to be harmful, but this was not the ground taken. On the contrary, in two papers on alcohol previously read before this society, and papers read elsewhere, I have pointed out that the adulterations are cheats rather than poisons. It is the uncertainty and deception to which I call attention.

Although objection has been made to the third proposition on the ground that alcohol alone or simply diluted will not answer, yet we have these objections well refuted by the fact just stated by Dr. Woodbury, that in one of the New York hospitals such a preparation is regularly and successfully used.

The second proposition has been misunderstood. It has been taken to mean that the use of alcohol in disease under medical advice has resulted in drunkenness, but this is not the meaning. It is the habit of moderate drinking in health that makes drunkards, and it is to the indifference of the medical profession to this habit that the second proposition relates.

The whole question, it seems to me, is a most important one. The terrible effects of alcohol are seen in all directions, and if the restriction of it is needed—and I do not see how any one can doubt that fact—such restriction must only come by active assistance of those who know the facts best. It will never do to temporize with vice. No method will answer with any form
of crime or vice except continuous, unrelenting opposition. It is a mistake to suppose that widespread and deep-rooted habits are unconquerable. Did time permit, it could be shown that traits of human character, as vicious and deep-rooted as the tendency to drinking, have been eradicated by persistent effort, and what has thus been done can be done again. I am fully of the opinion that the tavern finds its best support in the idea, so general in the community, that physicians consider the regular use of a little alcohol not injurious. When the medical profession is true to itself, and teaches that alcohol should never be used except for a specific purpose and under continued medical advice, the tavern will lose its best hold on the community.

The statement of Dr. Wood, that he is fully convinced that we do not need alcohol in health, and that indulgence in it moderately on occasion is no more hurtful than over-eating, certainly leans in favor of my first proposition.

Miscellany.

Therapeutical Notes.—*Placidia Ergotoides* as a Substitute for Morphine.—M. Landowsky ("Gazette hebdomadaire de médecine et de chirurgie," August 31, 1883) has found in a few experimental cases that *Placidia ergotoides* possesses valuable sedative and narcotic properties. It is a leguminous plant, which grows in the volcanic soil of Jamaica. It takes its name from the property it has of narcotizing fishes—a property which the natives have long put to practical use. In the case of a physician suffering from severe toothache, three grammes of an alcoholic extract of the bark (one part of bark to four of alcohol) were followed by a calm sleep of twelve hours, which did not leave any dullness or other disagreeable after-effects. In the case of six patients, suffering from various painful affections, M. Landowsky used *Placidia ergotoides*, instead of morphine, with happy results. "Without being conclusive, because of their small number, these experiments are nevertheless encouraging. If they result as it is hoped they will, our materia medica will have a precious substitute for opium, with, moreover, this advantage, that it does not cause headache or other malaise, and does not constipate."

Professor Ott, of Easton, Pa., ranks *placidia* as a narcotic to which both the higher and lower animals are susceptible. In his hands it dilated the pupil, diminished the number of the respiratory movements, produced severe salivation and diarrhoea, and lessened the frequency of the cardiac pulsations. In large doses it produced general paralysis and death from asphyxia. He found it to resemble morphine in many respects. He believes it can be used to advantage as an analgesic and hypnotic in neuralgia.

Dr. Otto Selter, of Würzburg, has observed good effects from *placidia* in the obstinate cough of phthisis.

The Physiological Action of Barium Chloride.—Professor Sydney Ringer and Dr. Harrington Sainsbury, in a recent paper ("British Medical Journal," Aug. 11, 1883), detail the results of their interesting investigations respecting the physiological action of barium chloride on the circulatory system. The special object of the experiment was to determine whether the effects produced on the heart and vessels by the drug were due to its direct action on the tissues or to its indirect action through the nervous system. The animals used were frigs and tortoises. The conclusions reached may be summarized as follows: Barium chloride resembles digitalis markedly in its action on the circulation. It retards the pulse-rate, increases the length and force of the cardiac systole, causing ultimately systolic arrest, decreases the calibre of the arterioles, and increases the blood pressure. All these effects are produced when the circulatory system is freed entirely from central nervous control, and they must therefore be due to the direct action of the drug on the tissues. The excited heart was arrested in full systole by feeding it with blood containing barium chloride. The local application of a dilute solution of the salt caused local spasm at the point of application. It was impossible to affect the caliber of the vessels through the nerves apart from direct local action. "The therapeutic value of barium chloride yet remains to be determined. The drug is clearly a very powerful one, and in this respect is widely separated from its chemical analogue, calcium chloride. As to the direction in which clinical observation should extend, we get a clear indication from the digitalis-like action of the drug."

"Sulfarine," or Crystallized Liver of Sulphur, for Odorous Sulphur Baths.—A new liver of sulphur, under the name of "sulfarine," or crystallized liver of sulphur, is recommended ("L'Union médicale," Aug. 14, 1883) for use in the preparation of sulphur baths. By dissolving it in water it affords a bath having all the medicinal properties of an ordinary sulphur bath, without the disagreeable odor. "Sulfarine" is obtained by precipitating the sulphur from the alkaline sulphide of potassium. This eliminates the sulphuretted hydrogen, and reduces the sulphur to its molecular state. "Sulfarine" is the product of this operation crystallized. "Sulfarine" baths may be taken at home in ordinary bath-tubs, without fear of affecting the metal of which they are made. They are said to be very useful in the treatment of diseases of the skin, rheumatism, gout, paralysis, scrofula, chlorosis, and anemias.

American Pharmacy in Europe.—The following extracts are from the "Monthly Magazine of Pharmacy, Chemistry, and Medicine," whose correspondent was in attendance at the great International Pharmaceutical Exhibition at Vienna. They are their own explanation: "Since I have mentioned America, I should not forget to say that Messrs. Park, Bond & Co. (New York) have an important exhibit here, in which we find represented almost all that the apothecary's art can do in America. In the absence of important exhibits by English and French houses, the Germans are evidently pleased at the extent and beauty of the American display. A great portion of it is devoted to newer American drugs, which are as yet very little known in Europe, and are classed as raw products from which the pure active principles have not yet been extracted." "We are pleased to note that the same firm have been awarded the gold medal of the First Viennese International Pharmaceutical Exhibition, held at the Austrian capital from August 11th to 26th, inclusive."—*Editorial in Therapeutische Gazette*, October, 1883.

The Great Intrascapular Ligament between the Astrapidues and the Os Calca.—Professor Brodersen, of Aberdeen, writes as follows in a recent number of the "Lancet": The fore part of this ligament is firmly exposed on its outer aspect in the ordinary dissection of the lumbar region of the foot, and useful views of the concealed part of the ligament may be obtained by transverse vertical sections made with the saw through the astragalus and os calcis; but even these two methods combined failed to give a satisfactory view of the ligament, or to enable us to see clearly the functions of its several parts. The following is the method I employ: Take an ordinary ligamentous preparation of the tarsus. With the saw divide the astragalus into three parts, so that the narrow middle portion shall carry the entire upper attachment of the ligament. The middle portion should be about one third of an inch in breadth, but a little broader (five lines) in front. The inner cut should, in front, be close to the inner edge of the cartilage of the head, leaving a shaving of the neck with the middle piece, and, behind, be at the hinder end of the internal malleolar facet. The outer cut should extend from the fore end of the external malleolar facet to close to the inner edge of the groove for the flexor pollicis tendon. The sections should be vertically. Only a narrow margin of bone remains on each side of the ligament, so that the attachments and functions of the ligament may be clearly seen. If the section prove to be too thick below, it may afterward be sloped near the ligament. The demonstrator, however, will soon learn how to make these sections accurately and easily in the dissecting-room. The lateral portions of the astragalus should be left hanging to the os calcis by portions of the lateral ligaments of the ankle, or attached by guttae; and thus be readily replaced.

We now see the whole extent of the intersosseous ligament from before backward, and its length, direction, and thickness at different parts, and can demonstrate the functions which it performs in relation
to the various movements of the astraglus or os calcis. The method is useful also from the way in which it presents for study the joints on either side of the interosseous ligament, and enables the parts to be again replaced. In making a dried preparation of the ligament by the above method, the lateral portions of the astraglus may be attached by a cattgut cord, piercing them, and dipping into the os calcis below the ligament, so that when the cord is pulled the three pieces go into position.

I may mention also a method of exposing the interior of the ankle-joint, which may be combined in the same preparation with the above method of exposing the interosseous ligament. Having dissected in the usual manner the ligaments of the ankle and tarsus, divide the portion of tibia by an antero-posterior vertical median cut with the saw. If it is for the ankle-joint alone, the preparation may include several inches of the tibia; if it is for a preparation to show also the interosseous ligament by the above method, half an inch of the tibia will suffice and be more convenient. The two side-pieces of the tibia now fall asunder, displaying the whole interior of the ankle-joint and giving an inside view of the ligaments and their points of attachment. If the astraglus be then divided by the above method, the lateral ligaments of the ankle serve for the lateral pieces of the astraglus to hang on by. The three pieces of the astraglus may be replaced, and then the two sides of the leg, and thus the whole built up again. Such a preparation, with the facility which it affords for opening out the joints and again replacing the parts, will be found very useful in the anatomical school.

I have shown these methods for many years and to various teachers of anatomy, but, so far as I am aware, they have not yet found their way into any of the text-books.

Congress of Surgical and Orthopedic Instrument-Makers.—A congress of surgical and orthopedic instrument-makers took place at Frankfort-on-the-Main on the 10th, 11th, and 12th inst., to form an association for the purpose of improving the conditions under which the trade is carried on. The association consists already of one hundred and twenty manufacturers from various parts of the world. The executive committee consists of Messrs. Letter, Vienne, Winder (Berlin), Walter-Bondetti (Basle), Krohne (Krohne & Sassenmann, London), Sinskey (Konigberg), Wendisch (Dresden), Labaeh (Littig), and Fisheker (Freiburg-in-Baden).

The "Sanitas" Absorbent Pad.—This contrivance is essentially a T-bandage, to be worn during menstruation. The perineal portion consists of absorbent cotton inclosed in a network of thread. The use of the pad has been explained to us, and we have no doubt that it will prove very convenient, especially during a suroujourn away from home. The pad is made by Mr. Mann Ende of Hooaken. Some of the pads are disinfectant.

Copper and Choler.—An engineer, living at Westminster, has forwarded the following interesting information to the Académie des Sciences, and it has been communicated by that body to the members of the commission appointed to investigate the subject. In 1871 the writer visited the copper mines at Falun (Sweden). All the miners were inoculated with copper vapors, which pervaded the atmosphere and destroyed all vegetation, but had no deleterious effect on the human organism. When choleram raged in Sweden, the royal family took refuge at Falun, where no one had been attacked.

Napthol in the Treatment of Skin Diseases.—Dr. Arthur Van Harlingen, of Philadelphia, reports in the "American Journal of the Medical Sciences" for October, 1883, the results of his experience with the use of this drug, which was first brought to the notice of the profession by Professor Kaposi, of Vienna, about two years ago. He finds it is one of the most efficient and agreeable remedies for scabies which has as yet been brought forward. Both in the rapidity of its action and its beneficial effects upon the inflamed skin it is superior to any of the means ordinarily employed for the cure of this disease. Its exact place in therapeutics remains to be ascertained, but he is inclined to think that it will not prove an unimportant one. In eczema it has failed in his hands to give the same beneficial results as in Kaposi's.

In most cases of vesicular and in acute eczema generally its action is simply that of an irritant. On the other hand, it has a limited field of action in the cure of a certain number of cases of squamous eczema of the scalp. In its opinion, it is a valuable addition to our external means of treatment in psoriasis. Kaposi speaks well of it in psoriasis of the scalp in particular, and his experience would lead him to place it near schabriso-and pyrogallic acid in effectiveness, without the neutralizing disadvantages of either of these drugs. In eruptions of the scalp napthol is a decided addition to our means of treatment. While inferior in some respects to sulphur or carbolic acid, it has a certain range of usefulness which further experience will in all probability more exactly demonstrate. Napthol is highly lauded by Kaposi in the treatment of hyperhidrosis, but in Dr. Van Harlingen's hands it has failed entirely, although used strictly according to his formula. He considers it quite valueless in this disease, so far as his experience goes. His experience leads him to regard its effects in ringworm as inferior to those of almost all the remedies at present used, and as almost entirely inefficient in most cases of tinea versicolor. In pediculosis he has had no experience, but in a single case of pediculosis it passed favorable.

The New Boston Dispensary.—The laboratory and dispensing department are said to have been fitted up in a most admirable manner, being the best appointed of any in the country. This branch of the institution will be under the personal direction of Professor Frederick Clark.

The American Public Health Association will meet in Detroit November 15th, 16th, 17th, and 16th.

A Remarkable Case of Morphone Poisoning.—In the first number of a new journal, the "Texas Courier-Record of Medicine," Dr. K. E. Beall, of Fort Worth, Texas, gives the following account of a case that occurred recently in his practice and that of his associate, Dr. W. A. Adams:

While somewhat under the influence of liquor, a man bought sixteen grains of morphone, and swallowed the whole amount at once. It is stated that there is no shadow of doubt that sixteen grains was the amount taken, and that he was not habituated to the use of any preparation of opium. In about an hour after swallowing the drug the man was found pretty thoroughly narcotized. There being no stomach-pump at hand, sulphate of zine, ipecac, and warm water were "forced into the stomach," and the pharynx was tricked with a bunch of feathers—all to no purpose; vomiting could not be produced. Fluid extract of belladonna and citrate of caffine were then injected subcutaneously, and Flagellation and constant movement were resorted to. Such effects it soon became necessary to abandon, and the livid man was laid down, when only an occasional respiratory movement was observable, and very soon respiration entirely ceased. Artificial respiration was kept up for twelve hours and a half, during a great part of which time the man's appearance was so desolate that some physicians among the bystanders were unkind enough to remark that it was done for effect on the crowd, and some of the latter even went so far as to propose that the officiating physicians should make way for the undertaker. Whenever the heart's action showed signs of failure, watching and ammonia were used hypodermically. In all, about forty drops of fluid extract of belladonna and twenty grains of citrate of caffine were used. "The careful use of the galvanic current" is mentioned as having been employed, but the method is not specified. The man recovered.

The Tarnier Forces.—In an admirable Report of the Section on Obstetrics and Gynecology (reprinted from the "Transactions of the Medical and Chirurgical Faculty of the State of Maryland"), Professor William T. Howard, of Baltimore, says: "That Tarnier's forceps have great advantages over all others in delivering at or above the pelvic brim, or the two upper inches of the pelvic cavity, has, it seems to me, been demonstrated. But I have in two instances, in consultation, succeeded in accomplishing delivery at the inferior strait by their use; one, a right oblique occipito-posterior position, and the other, a brow-face to the left, when two experienced and skillful accoucheurs, as well as myself, had failed with Hodge's and Simpson's forceps. It properly
The Use of the Colposcouter as a Preliminary to Freund's Operation.—In the proceedings of the New York Obstetrical Society, meeting of February 6, 1883 (published in our issue for April 14, 1884, p. 199), it was stated by Dr. Louis Freund (who had found it feasible to raise the uterus even as high as the umbilicus by means of pressure with the colposcouter for a week before the operation) that he (and not Professor W. A. Freund, of Strassburg, by whose name the operation is known) who first made use of this device. In an article contributed by Dr. M. B. Freund to the "Zeitschrift für Geburtshülfe und Gynakologie," Band VI, Heft II, a copy of which he has kindly sent us, we find this statement: "Den genannten Zeichen hat ich durch Elevation des Uterus durch die Operation vorauszehende mehrjährige Kegelshurz und durch letztere durante operatione am besten zu begrenzen, ein Verfahren, zu dem ich durch eine Mitteilung von Heizmann ("Wiener medizinische Presse," xvii, vom 14. Juli, 1871) gedacht wurde," etc.

The Growth of the 'Lancet.'—We may pardon the "Lancet" for the following sexagenarian eulogy, which appeared in its issue of October 6th:

'Within one day of the date of the present number 'The Lancet' will have been in existence sixty years. The late Mr. Wakley's modest venture was first issued on October 5, 1828. There are probably not ten practitioners in the United Kingdom who were at that time in the active practice of their profession and who can recall what was the first effect of the journal on the professional mind. 'The Lancet' was the original weekly journal for the advancement of medicine as a great power among the masses of the people. We may say so much, because no one now disputes the fact. There had been journalists in medicine before Mr. Wakley took up his pen. At that very time Dr. Rodgerie Macleod and Surgeon John Bacot, who had not long left the surgery of the Grenadier Guards, were conducting a journal which, from a purely scientific point of view, was exceedingly well done, and was sometimes not badly illustrated. They, too, were the successors of other able editors, notably Dr. T. Bradley, Dr. Samuel Puttigall, and William Hutchinson. But these had all represented the profession in 1815. The profession, the whole profession, and nothing but the profession, was its motto. Our founder took a different position. He took the people, the whole people, and nothing but the people, as his constituency; and while he never deserted the real and long-sighted interests of medicine, even as a compact professional body, he held by his text and preached from it until he succeeded beyond, far beyond, his own most sanguine expectations. In his preface to the first number of 'The Lancet,' Mr. Wakley tells to whom it was addressed. It was intended to be useful to the medical and surgical practitioners of this city—London—whose avocations prevent their personal attendance at the hospitals; to country practitioners, whose remoteness from the headquarters, as it were, of scientific knowledge leaves them almost without the means of acquiring its progress; to the numerous classes of students, whether here or in distant universities; to colonial practitioners; and, finally, to every individual in these realms.' The last promise—which we have italicized—was the keynote of 'The Lancet,' and it is by that it has become known and recognized as being above all classes and clique. The undertaking was, and has always remained, arduous. In carrying it out, medicine as a literature has had to be simplified; 'mystery and concealment' killed; 'ignorance and mystery' made 'synonymous'; 'ceremonies and signs' deprived of their charms; 'hieroglyphics and gilded serpents' deprived of their power to deceive.' These things were to be destroyed, and new things were to be introduced. When we note that the first article in the first 'Lancet' was an introductory lecture to students at St. Thomas's by Sir Astley Cooper—a lecture, by the way, as fresh to-day as when it was delivered—a show, in part, the full life of a now sexagenarian period, and also the success of a system which has but once changed hands, and which, at the death of the founder, twenty-two years ago, devolved as a sort of heirloom on his son, Dr. Wakley, the present editor. The first principles of free and independent journalism have been and will be faithfully maintained. To what extent the little double sheet has gradually increased, this day's impression, which consists of ninety-six pages, will indicate.'
Lectures and Addresses.

A LECTURE ON THE
TREATMENT OF GUNSHOT WOUNDS,
DELIVERED AT BELLEVUE HOSPITAL MEDICAL COLLEGE,
BY Sir WILLIAM MacCORMAC,
SURGEON TO ST. THOMAS'S HOSPITAL, LONDON.

GENTLEMEN: When, some time ago, Dr. Dennis invited me to come and make an address before you upon any subject I might choose, I begged that he would excuse me, because I felt that the number of subjects worthy of bringing to your attention was so great that it would be impossible for me to select one from among them. He, however, speedily disposed of that objection by choosing a subject for me, and so I ask you not to regard me as responsible for my presence here to-day, but desire you to understand that the whole responsibility rests upon him. The subject which Dr. Dennis has chosen—namely, the treatment of gunshot wounds—is a very large one, and so broad that it can not be worthily disposed of in a single lecture; moreover, it is one of very great interest and very wide application in surgery, and I must confess that I feel great hesitation in attempting to speak upon it at all in this place, because in this city, perhaps more than in any other with which I am acquainted, there are surgeons who have had a much larger experience in this branch of the late civil war than the surgeons in any other part of the world have. It seems to me, therefore, very much like "carrying coals to Newcastle," as they would say in the old country, for me to speak to you on this subject at all. The vast experience of your surgeons in the late war is embodied in those excellent volumes issued by the Surgeon-General, which, for size, magnificence, completeness, and profuseness of illustration, are equalized nowhere else in the world. The other day I had the privilege of visiting the Army Medical Museum, under the supervision of the distinguished Dr. Williams, and there I saw examples of surgery, in specimens collected from far and wide, illustrating the effects and results of the treatment of gunshot wounds in recent wars. These showed such a wide experience in this branch of surgery that when I decided to speak to you I thought that neither the time nor the place was altogether fitting for me to make any very general remarks on the surgical treatment of gunshot wounds, and I thought you might be more interested in a brief account of my own personal experiences.

These experiences, or at least one phase of them, I think it is not unifying that I should relate to you here. The special matter I wish to explain occurred twelve years ago in the Franco-German war, under the supervision of one of your own distinguished countrymen. I am only speaking the opinion often expressed by very competent authorities when I say that the ambulance service of that war was superior to any other ever known. At the head of that celebrated ambulance service was placed by the government a man known all over the world as well as here, and beloved by every one who knows him, Dr. J. Marion Sims. I was connected with that ambulance service, and stationed in Paris, when our orders came to hasten to the camp of the contending army as soon as possible. We immediately started off fully equipped, and, after innumerable delays, we at length reached the encampment. We stopped near a place that was strongly fortified, and the opposing armies were not far distant from us. There was not a single uniformed soldier in the whole place where we were, and the only doctor I could find was an old French surgeon, who begged us to wait there till the wounded were brought in. We, however, pushed on to the railway station before halting, and while there, lying in our barracks, an incident occurred which was striking enough at the time. I was not asleep, though most about me were, when in the middle of the night a train arrived, or rather a strange sort of train made up of a cattle-truck attached to an engine, on which was the Emperor of the French, with two or three officers attending him. They stopped at the gate of the town and asked admission; they knocked and knocked, but no response was made, and so for one hour the Emperor and his officers stood there waiting for admission to the town before it was obtained.

There was nothing for us to do that night, but the next morning the disabled troops came pouring in by thousands, and we were very glad to accept of the only hospital there, which contained about four hundred beds, fairly comfortable and clean, and well enough fitted for the purpose. At dawn the battle began, and it lasted all that day. The wounded soon came in great numbers, and all the beds were quickly filled; then the floor and the staircase were packed, every available house and church in town was crowded, all the country houses around the town for miles about were filled, and thousands of wounded men were thus disposed of. Of course, I need not say that all we surgeons, few in number, could do for so many sufferers was very little, but yet we did all we could. We were well equipped and had surgical appliances and instruments of various kinds, and we also had all the advantages of a hospital while working in the front rank of battle, where we were busy all day while the battle raged and shells were bursting about our heads. From our station we could see the German batteries on the rising ground in front of us training their guns on the French troops behind us, while the shot and shell flew over our heads. At times a stray shell would burst near us or strike one of our buildings, but it was evident that the shots were not leveled at us. An officer in the German army, whom I met the other day, told me that he was in command of the battery in front of us at that battle, and he had recognized our flag, which marked the hospital, and had directed his shot away from us intentionally. That officer was a son of the distinguished surgeon von Langenbeck. Another son was shortly after shot down four times in battle, and he lay for hours, yes, for several days, unrecognized before his father found him.

We had certainly a large number of operations to perform immediately, in the line of amputations and dressing fractures and wounds of all kinds, but we left all resections until a later date. Such a vast and varied experience is
rarely given to any one in so brief a time, and, of course, we availed ourselves of the opportunities as well as we could. We, however, had numerous difficulties to contend with, for we were treating French soldiers who were demoralized by defeat, and, on account of the vast number of patients, they suffered for a time from inadequate nourishment and from an insufficient supply of appliances necessary for all. It was only for a short time, however, that we were thus embarrassed, for soon large extra supplies were forwarded to us. Yet at that time we did not have the advantages of the antiseptic methods of treatment which have since effected such favorable results, and it was quite distressing to see, in spite of all our care, our patients, with wounds and compound fractures, die of blood-poisoning or erysipelas, which spread from one to another.

I said that we left our resections for a later day. I agree with von Langenbeck that we should be very careful how we perform resections as primary operations under such circumstances. Primary resections are not satisfactory, or favorable to life, and I think they are infinitely risky. These late resections then performed were many of them on soldiers who were soon after sent away, and they could not all be followed up, but very satisfactory results were sometimes obtained. There are many reasons why such operations as resections should be performed late, after the primary inflammation has subsided, for, after that time, those cases in which amputation should be performed have been selected out, and, besides, the numerous small pieces of bone which are always found in comminuted fractures about the joints have become separated and have disappeared in the discharges, so that the amount of bone that can be saved may then be determined more accurately. A fracture made by a gunshot wound is almost always a comminuted fracture, and later on you can always ascertain the limitations of the diseased process more accurately than at first. We can, however, here perform partial operations immediately, and I think that recent experience has clearly shown that these partial operations are not only less dangerous than primary resections, but that they are often followed by more satisfactory final results. Late on the periosteum about the fractured bones becomes thickened and tough, and rapidly produces new bony tissue, while in the early period the periosteum over a newly fractured adult bone is especially thin and easily torn, besides which it possesses very little osteogenetic power. For these reasons I think that resections are more wisely performed at a late period.

I do not wish to weary you with a citation of cases, but I do want to give you one or two illustrations, showing you what favorable results may be obtained in this class of operations. Neither would I dwell on the greater risks which attend operations on certain joints, but I will merely state that the wrist, ankle, elbow, and shoulder joints are best fitted for resections, while the knee and hip joints are least fitted for operations of this kind; and I think experience has amply shown that the statement that these joints had better be left alone is one of extreme utility.

Now, I wish to tell you of one case I know of as an illustration of the good results obtainable in these late resections. There was a young officer in the German army in the late war who was shot through the ankle joint, and there was very extensive shattering of the lower end of the tibia and a large part of the fibula. Von Langenbeck excised the lower three inches of the tibia and the larger portion of the fibula, and the result was that the man not only made a good recovery, but there was no change in the appearance of the joint, and that its function was good is proved by the fact that a few months later he walked all the way up to the top of the famous Monte Rosa, in the Alps, which is no easy task for a man the function of whose limbs has never been impaired. I refer to this case because it is somewhat unique.

Some ten or eleven days after the battle I was speaking of a short time ago, a French chasseur was brought into our hospital who early in the day of the fight had received a wound in the face, but who, nevertheless, had gone on fighting till late in the afternoon, when he was again wounded by a shell which burst and shattered the shoulder and elbow joint on the right side. When I first saw him, ten days later, the shoulder joint was improving, but there was still a large open wound communicating with the elbow joint. I opened the shoulder joint and removed the upper end of the humerus, also numerous pieces of comminuted bone from the shoulder and the elbow joints, and then excised the lower end of the humerus and the upper end of the ulna and radius. After a time the man recovered completely and went home, and so passed out of my observation. But I have heard from him every year since, for he writes me every Christmas telling me of his condition, and I have found that the first result was a necrosis of a considerable portion of the remaining part of the humerus; but later on he said that there was a very complete reproduction of the shaft and some of the upper and lower ends of the humerus. He has been under the constant observation of a skilled surgeon at his home, who has explained to him the onward progress of repair, and he reports to me. He can now perform quite readily all the underhand and rotatory movements with the shoulder and elbow joints, and he can do whatever light work he wishes to. He can saw wood and go through the motions necessary to plane a board, he can use a spade in digging, he has rolled a heavy cask up an inclined plane to get it in his cellar, and he finds that he can use that arm for all the practical purposes of life. The deformity left is so slight that, when his family doctor, at my request, measured the amount of shortening of the arm and sent me the results, he gave me the measurements from the acromial process of the scapula to the external condyle of the humerus, and he described these as if they were in their normal condition and had never been removed, evidently not being aware of the exact nature and extent of my operation. So these portions of bone must have been restored to nearly their former shape. By that operation his arm was preserved to him and is now a useful member.

I think, then, that I have shown you, in the first place, that operations of this kind—namely, resections—had better be performed in the secondary period, that they had better be partial if possible, and that certain joints are more fitted for operations of this character than others.
Now, another thing which I think I have learned, and desire to teach you, is, to avoid probing gunshot wounds altogether, or as far as possible. I have seen great harm come from this practice, and the fact can not be too strongly impressed upon you that the bullet itself is of very little importance in these cases. I know that nearly always the first thing that a patient who has been wounded will ask the surgeon is, "Where is the bullet lodged?" and then he will expect to be relieved by its removal. I think that under these circumstances the surgeon is too often apt to be so inconsistent as to try to please the patient and accede to his wish. Any one who has had much experience with gunshot wounds knows how easy it is to fail in finding the ball, and how difficult it often is to distinguish by the probe between a piece of lead and an exposed surface of bone, or a piece of fascia or a tendon, and in such cases, if he does not succeed in finding the bullet with the probe, he is very apt to search for it with his fingers; then he tries with one forceps and then another to extract it, and in this way septic matter is almost necessarily introduced, so that a wound of a joint which might otherwise have healed perfectly without a particle of suppuration is doomed to suppurate, and possibly the whole limb will in consequence be lost. Besides, experience shows constantly how frequently bullets become lodged in muscles, bones, or some of the viscera, and there become encapsulated and never cause further trouble. The point I wish to insist upon is, that there is infinitely more danger created by the surgeon who attempts to search for and extract a bullet than would result from leaving half a dozen bullets to take care of themselves. In all the pathological museums throughout the world may be seen specimens of bullets lodged in lungs, liver, brain, and bones, where they had remained imbedded for years without inspiring the functions of these organs. At the museum in Washington I recently saw a specimen from a man who had received a gunshot wound which had fractured the upper end of the femur, and the bullet appeared to have lodged just below the cartilaginous surface of the lower end of the femur. The surgeon who had attended him at the time of the injury had thought that there was not a wound of the joint, and so had not operated, but had left it alone. The man lived for years afterward, and after his death this specimen of the bones was brought to the museum at Washington; it was found then that the bullet had caused no injury to the joint at all, and it had not troubled the man for years. I wish by this recital to impress upon you that bullets left to themselves are not such dangerous things as they are generally supposed to be. In the recent Turkish and Russian war there was also a strong practical illustration of the value of this let-alone policy. A very distinguished surgeon and a noted professor, both in Berlin and in St. Petersburg, introduced into the hospital the plan of treating all wounds aseptically, and he had to deal with a great many penetrating wounds of the knee. These he treated by not searching in the tract of the wound with instruments, but he immediately put them up in antiseptic dressings and kept the limb immovable. I quote from memory when I say that nineteen out of twenty-one recovered, not with stiff joints at all, but with movable joints. If you can trust to the evidence of such a series of cases as that, coupled with what I have heard von Langenbeck say—that he did not believe that a single case of a wound of the knee joint in the whole Franco-German war recovered—you can see clearly what striking advances have been made recently in the treatment of gunshot wounds. Another thing told me by a surgeon of distinction who has had much experience in several wars in the past few years, was that he never interfered with or probed a gunshot wound of the knee, and his published reports show that the results of these fractures in his hands have been infinitely better than those of any other surgeon.

This is another illustration of the importance of avoiding all interference with gunshot wounds. Professor Esmarch, of Kiel, whose reputation you all know, preaches from the text, "don't injure" or "don't do damage," and refers to the interference with gunshot wounds; and I think that I have now said something to show you the importance of such a maxim.

Gentlemen, I should like to refer briefly to another question at this point, and that is in regard to the treatment of gunshot wounds of the abdomen. Some months ago Marion Sims, who has honored us by his presence to-day, published in one of the medical journals an interesting series of papers in which he said that these injuries should not be left to themselves; but what he proposed was, that the abdominal cavity should be opened and searched, the bullet be found and extracted, the peritoneal cavity then be cleansed antiseptically and closed, after which treatment it might be possible for recovery to follow where death was otherwise almost inevitable. Now, there is very much in favor of following out this plan, for in these days the abdominal cavity is opened frequently for the removal of diseased organs, and I think that every viscera except the liver has been removed successfully. Portions of the stomach and intestines have been excised, and kidneys, ovaries, the uterus, and tumors of these organs and of the intestines, and, in fact, foreign bodies inside of the intestines, have been removed, and recovery has been the rule; therefore there can be no good reason why such an operation as that suggested should not be performed in these otherwise fatal cases of gunshot wounds. The danger of leaving them alone is, that an extravasation of blood may occur within the peritoneal cavity and set up a fatal inflammation, but yet it is possible for a bullet to become encapsulated even here without doing great harm. The intestines may not be injured although the abdomen is penetrated, for you know that a bullet has frequently passed through the whole abdominal cavity without damaging the intestines at all; yet they may be severed at some point, and it is, therefore, advisable to lay open the abdomen and search for a wound of this viscus, and, if found, sew it up. When I think of the fact that, in a case where the bladder was ruptured in the course of an operation for the removal of an ovarian cyst, the urine poured out into the abdominal cavity, and yet, after washing it out, the patient recovered, I do not think that in a case of gunshot wound of the abdomen we should stand by and fold our hands in despair, but we should give the patient the benefit of the only resource left.
If I were not afraid of tiring you, gentlemen, I should like to give you the evidence of distinguished surgeons showing how successfully antiseptic surgery may be carried out on the battle-field. All surgeons have long been thinking and devising plans of carrying out this method in time of war, and it has been found that certain modifications can be advantageously made, and that certain of the minor details may be omitted. I think we have found that the spray of carbolized vapor may be eliminated, and that we may accomplish the same object by frequently douching the parts with a carbolized solution. Of late there have also been discovered many means by which antiseptic substances can be packed in a very small bulk, and so be easily transported. Though it would be interesting to describe some of these devices, yet they are too numerous for me to even mention at this time. One of the best preparations at our disposal, however, is iodolform, for it is easy of application, its bulk is small, and, for dressing such external wounds as I have spoken of, there must be a very great future before it.

I would like to give you here another illustration of the marked success which is due to the introduction of antiseptic dressings in the treatment of gunshot injuries. You know that only lately England had a war of brief duration in India, yet in that short space of time there were a considerable number of men wounded, and among these cases there were many of severe injuries of the limbs requiring amputation. An expedition was sent out to the seat of war by the Government, equipped with every improvement in antiseptic surgery that could be devised, and many fractures and amputations were treated on this method. The result was—and again I quote from memory, and can not vouch for the exactness of the figures—but, if I remember rightly, out of one hundred and thirty-six wounded men there was not a single instance of any one suffering from any form of infectious disease whatever; there was no erysipelas and there was no pyaemia. Any one who knows the history of such campaigns in past years, before the antiseptic method was introduced into military surgery, knows that such a result as this is unprecedented.

Gentlemen, after all, What is surgery? Do you say it is the work of a man's hand? Do the surgeons of to-day work with their hands alone? Not so, but with their hands and hearts and brains. Surgery is a battle with Death, in which the surgeon is often vanquished, it is true; but never before have his equipments for the fight been so complete, nor his victories so glorious, as at the present day. We speak of conservative surgery a good deal in these days, but I think that is a bad and useless term. For is not all true surgery conservative? I believe that the word is meaningless, and should be banished from our professional vocabulary.

The surgeon should be a man of judgment, and, in his training, should receive the highest and broadest culture which our schools and colleges afford. The field of instruction is no doubt vast, but, on the other hand, human intelligence seems capable of growing with the requirements for its action. In the future, no doubt, we shall witness new applications of the surgeon's skill, and new methods of dealing with casualties, and the same glorious advances, I feel assured, await the surgeons of the future as have marked the progress of the surgeons of the past. Much has been accomplished by those who have come before you, but presently their duties will fall upon you, and that you may all be fully prepared for the work is my highest wish.

In closing, I wish to thank you much for your courtesy in so attentively listening to what I have had to say on the few points which I have been attempting to impress upon you, and to express my appreciation of the honor done me by your instructors in asking me to speak to you in this place. And now, on the point of returning to my own country, I can say that I go with only the happiest recollections of my visit here, and I may add that I am not vain enough to believe that the kindness and hospitality constantly showered upon me here were at all personal in their intentions, but rather that they are the expression, on the part of the more highly-educated portion of this community, of their love and respect for old mother England, for "the old country," and for "home." During the eight weeks of my almost incessant traveling since I came to this country I have heard but one expression—that of good-will—toward my own people, and I wish now to assure you how cordially this feeling is reciprocated at home, and I hope that this feeling of mutual good-fellowship and good-will may never cease or become weakened.

DECOMPOSED ANIMAL MATTER IN WATER USED FOR DRINKING AND DOMESTIC PURPOSES

FOR FULLY TWO WEEKS OR LONGER, WITHOUT ANY DELTERIOUS EFFECTS, BY A GARRISON OF AT LEAST EIGHTY SOULS.

By J. C. McKee, M.D., Surgeon, C. S. Army.

The water-tank on the cliff at Fort Winfield Scott, located on the "Golden Gate," San Francisco, Cal., which supplies the officers' quarters, soldiers' barracks, Fort Point, etc., is divided into two compartments or divisions, each holding twenty-seven thousand gallons of water, pumped to this elevation by a wind-mill from a spring on the reservation. A waste-pipe of some three inches in diameter carries off the overflow.

For some weeks complaint had been made that the water had a bad odor and a sickening, nauseous taste.

The tank was securely covered by two-inch board planks, with two trap-doors, one over each division, locked by padlocks, so that nothing could be thrown or get in from the top. It was thought and said that the complaints were made by over-fistulatious palates, and they were laughed at.

At last the post quartermaster opened one of the trap-doors by wrenching off the rusty padlock, when was found floating on top of the water, in an advanced stage of decomposition, the carcass of a "pole-cat or skunk" (quite a common animal on the reservation).
The mouth of the waste-pipe being unprotected and open, the animal had crawled up and fallen into the water, and, being unable to escape, was drowned. There is no telling how long it had been there; perhaps some months, as the walls of the foul and fatal carcass were seen floating through the water in all directions.

Prompt measures were taken at once; the water was drained off, the walls of the tank were scrubbed and thoroughly cleansed, and it was then refilled with fresh water.

It certainly is remarkable that water in daily use, saturated and infected with the decomposition of this horribly nauseating animal, did not affect in some marked manner the men, women, and children who had used it steadily for weeks.

I fully expected the development of some filth disease, but no serious results followed. However, to show the effects of the imagination after the discovery, many persons had a sense of gomness, loss of appetite, and suppressed lingering nausea. Without any exaggeration, I must say that the horrid smell and taste lingered around my palate for days and weeks.

This is directly opposed to the theory that diseases may do originate in animal decomposition and filth. Query: Might not this have been almost too acute and overpowering to have attained a lodgment, when a milder poison would have been more insinuating and permanent?

Diseases and conditions of a typhoid character were expected, but none happened.

THE PATHOLOGY OF ACUTE LOBAR PNEUMONIA.
FROM A NEW STANDPOINT.

BY WILLIAM D. SCHUYLER, M.D.

Fourth Article.

An Outline Scheme of the Developing Local Process.—The Rationale of the Process.

Because of the facts and observations just given, I re-assert, in conformity to the hypothesis herein promulgated, that the local process is essentially the disease and the cause of the entire phenomena of pneumonia. Furthermore, I now submit the following scheme as embodying the principal steps and events of its formation and removal. It will be seen that these events, of which it is comprised, follow a regular order of development from the initial lesion, and that they sustain to each other the relation of cause and sequence. From which it is fair to infer that the first is in reality the cause of the anatomical process.

The first event in the formation of the local process is the occurrence of a functional insufficiency of one or more of the pulmonary capillaries which, although belonging to the pulmonary circulation, form a short segment of the systemic circuit of vessels. Stoppage of the circulating systemic blood immediately occurs through the affected vessels from this insufficiency, and, on account of the continuing influx of blood by the afferent vessels, complete obstruction to its passage is quickly developed. The blocked blood now dams back and naturally seeks collateral channels, which action causes such a degree of collateral congestion and capillary hyperemia and distension as results in (a) further functional insufficiency, and (b) the closure of these lateral avenues, by filling, against the further passage of the blood which is blocked and momentarily increasing in amount and pressure. All collateral relief being thereby cut off by the extension of the area of insufficiency and obstruction, the further result of the increasing volume and pressure which continue is now manifest within the direct vessels or those first affected, which consequently and naturally become distended to their utmost capacity. As the effect of this pressure is most felt by the vessels of the involved vascular tract least capable of offering resistance, the capillaries yield first before it. Being very delicate and free to expand, not being confined, these capillaries are quickly filled and distended to that degree that they give way structurally, and the second event to be noted, the anatomical insufficiency of the affected capillaries, results.

The third event, exudation, now quickly follows as a result of this structural impairment (anatomical capillary insufficiency), and of the continuing morbid pressure of the rapidly augmenting intra-vascular afferent blood, further aided by the respiratory movements—the expansion and contraction of the lungs, and cardiac action. The results of exudation are various and conservative, acting directly to promote a return to healthy, normal conditions. They are extra-vascular, general intra-vascular, and local (pulmonary) vascular. The extra-vascular are the filling and consolidation of the pulmonary structure throughout the area of the organ involved, the creation thereby of an intra-organic (pulmonary) pressure and a resulting enlargement of the organ in the same area, and, lastly, the production of an anemic state throughout of the consolidated section.

The general intra-vascular effects are depletion of the systemic blood in volume equal to the weight of the exudate, and, second, a re-establishment of an equalized general volume and blood pressure, both of which, as a result of obstruction, had become greatly deranged, while the local vascular effects are resolution of the congestion of the stage of engorgement, with a subsequent complete closure of the affected vessels by lateral compression.

Further general effects of exudation and consolidation are cessation of morbid process and the establishment of rest to the affected, consolidated structures. As a further result of rest, resolution actively advances, the consolidate softens; and lateral pressure upon the confined capillaries is therefore lessened, then removed. And at length, by force of the normal, systemic blood pressure which has remained and is being renewed, the capillaries are again opened by the circulating current. The function of respiration is also gradually renewed, and convalescence, which is now well advanced, goes rapidly forward until complete recovery is established.

On account of some morbid disturbance of that normal relation which otherwise, and in health, exists between the blood pressure on the one hand and the tonic resistance of the pulmonary functional, systemic capillaries upon the other, these vessels—which, as must be borne in mind, are but feebly supported anatomically, and whose walls are of
exceedingly delicate structure—one or of more them, or
those of a limited area, in a body, prove insufficient to sus-
tain and circulate forward their quota of the passing sys-
temic current of blood, and therefore are compelled to give
way and atonically dilate before the pressure to which they
are subjected. This insufficiency constitutes, as already set
forth, the first step, or event, in the pneumonia process
which follows, and so far is functional merely. The causes
of this insufficiency of the pulmonary capillaries, so far as
it is primarily created, has already been outlined under
pathogenesis, and may be briefly referred to here again as
predisposing and exciting. The predisposing condition has
been set forth as an asthenia. This may be structural, local
or general; or it may exist wholly as an atonic condition of
the sympathetic vaso-motor nerves; or, again, as a general
neurotic state. Additional predisposing conditions are gen-
eral vascular fullness, repletion; and, as given, a sensitive,
non-resistant, spasmocutaneous condition, such as re-
sults from some occupations, from functional derangements,
in febrile states, and in some chronic maladies, notably
in Bright’s disease. Examples of nervous atony are met
with in cases of acute alcoholism and after extensive tra-
umatism. The exciting cause is any influence which de-
termines the systemic blood in such volume with
force, upon the pulmonary circulation, as is adequate, in
their existing condition, to cause insufficiency of the capil-
laries, one or more, as stated.

The most frequently acting, exciting cause, undoubtedly,
is a sudden chilling of the surface of the body, known as
the taking of cold. Over-repletion with food, or espe-
cially from drink, is a cause. From whatever cause this ins-
sufficiency results, to the extent of its development a pas-
sive dilatation of the affected vessels immediately occurs.
The effect of this passive dilatation of the vessels upon the
blood passing through them is its delay; or partial, more
or less complete, stoppage. This delay in the discharge of
the flowing blood into the efferent vessels, acting in concert
with its unchecked arrival by the afferent channels, results
in an immediate local capillary filling, and an equal morbid
increase of intra-capillary pressure, which further increases
the insufficiency. These vessels now become quickly dis-
tended from this filling, and this distension on account of
their length (the pulmonary capillaries being very short)
and their looped form, and also on account of the greater
thickness, and therefore resistance, of the vascular walls on
either extremity of the capillary section—is, in short, accu-
lated, and probably aneurysmal in outline and character.

This abrupt sacculated character of the distension, by
favoring the formation of eddies in the current within them,
and by tending to create knuckles in the looped vessel and
suddenly close its lumen, quickly influences a more complete
obstruction and its extension to adjoining capillaries.
Furthermore, such extension of obstruction is favored by
the lateral pressure of these sacculations. On account of
the elastic character of the fibrous connective tissue which
sustains the pulmonary capillaries, which provides for
their free extension in any direction, and because of the close
contiguity of the capillaries to each other (the capillary
meshes, according to Kolliker, being but 0.002" to 0.003"
of an inch across), lateral pressure competent to be obstruc-
tive is not only made upon adjoining capillaries, but also
upon the primary efferent vessels, which, being only partly
filled, and hence not being sustained by a competent intra-
vascular pressure, are readily closed by this lateral pressure
of collateral action. However, that obstruction may result
from this simply insufficient state, dilatation of a capillary,
especially if such is somewhat sacculated, is evident from
the well-known condition of circulation through an aneu-
rysmal dilatation or sac, and may be demonstrated by pass-
ing a stream of croton, at its existing state of pressure,
through an imperfect hose—one insufficient to bear the press-
ure, which, therefore, will dilate locally whenever a full
pressure of water is turned on. In the former instance, in
regard to circulation through the aneurysmal sac, we know
the current flows eddies and is greatly delayed, and, in the
experiment alluded to, the stream of discharge will be seen
to stop whenever too great pressure causes dilatations.
At any rate, if a more or less perfect obstruction of blood does
not result in these vessels directly from and on account of
insufficiency, it is quickly developed, as the effect of the
additional filling and increased volume and pressure which
soon follow from the continuing arrival of the incoming
afferent blood. This obstruction to the passage and dis-
charge of the blood into the efferent vessels as rapidly as it is
received by the direct course, naturally causes it to well back
and seek an exit or passage through collateral channels. By
this action, made now more energetic by the pressure of a con-
stitutional organic reaction, manifested by the circulatory
apparatus, as shown in the increased cardiac and respiratory
movements, collateral channels are sought by the blood and
quickly over-distended. These vessels being unequal to the
strain put upon them of circulating, in addition to their own
quota of fluid, the obstructed blood, momentarily increasing
in amount and pressure, in turn give way similarly to those
first affected and become insufficient, in which manner the
area of insufficiency spreads, and therefore the extension of
the process, is brought about. Extension of the pneumatic
process through collateral action may be slow or rapid, accord-
ing to the number of vessels first involved. If but a single
capillary, or those of a very limited area are first affected,
the degree and effects of collateral action are slight; this is
because the volume of obstructed blood is comparatively
small, and collateral resources are therefore quite efficient.
This explanation may account for those cases of slow
development frequently met with. On the other hand, if
the capillaries of a considerable area become insufficient at
the same moment, the volume of the resulting obstructed
blood will be proportionally large, and collateral avenues of
escape will therefore be comparatively inefficient; hence the
large obstructed volume will at once immediately create a
disastrous pressure in collateral vessels, and extension will
rapidly result accordingly. Hence is to be explained the
slow development of an attack in some cases in which there
is an absence of adequate physical signs, although fever may
have been present some hours, a day, or longer; and, per
contra, the surprisingly rapid and extensive developments
which frequently occur in other cases.

The anatomical distribution of the pulmonary arteries,
their division and subdivision until they finally break up into capillaries, and their close contiguity, alluded to above, with the frequent anastomoses of the latter, especially in the adult, furnish a rational and scientific basis for the above explanation of the modes of extension set forth; for, owing to the structural arrangement, the immediately collateral vessels are first affected, the capillaries of a terminal artery before those of a collateral artery, and so on. And therefore larger and larger sections, as larger distributing arteries become blocked, are at last concurrently involved. Hence, the larger the area of a created obstruction, the greater and more sudden is the collateral action and its resulting effects.

At any rate, that an obstruction is created is clinically evident from the conditions of the abnormally distributed local blood volume now present, from the anemic state of the arteries beyond the point of obstruction, and the equally marked hyperemic condition and overtaxed fullness of the venous, efferent tract before or approximate to it, notwithstanding at this time the organic, circulatory, and respiratory functional forces are exerting their utmost powers to overcome the difficulty, and relieve the disproportion of volume and pressure which has resulted, and persists. The obstruction set up is at first circumscribed, confined to the capillaries which have become insufficient; but as insufficiency is extended in the manner set forth—namely, through an overpowering pressure by the blocked blood in collateral vessels through which it naturally seeks to pass the obstruction causing their insufficiency—so it (the obstruction) increases in extent, until finally its area is equal to the resulting process, the finally developed result. This increase of the area of capillary insufficiency and obstruction, and therefore of the pneumonic process as a whole, as a result, is generally very rapid. All may have been struck by the rapidity with which the complete consolidation, even, of an entire lung has been effected. By the process as described this rapidity is readily accounted for. When we take into consideration the structural delicacy of the capillaries primarily affected in this process, and their singularly unsupported condition anatomically, and thus fully appreciate their incapacity to offer resistance, on the one hand; and when, on the other, we take into account the locality, site of the lesion which has occurred; the vascular distribution which is first strictly collateral and next more distant; the energy which may be developed against an obstructive arrangement occurring in the vessels by an excited, exaggerated action of the physiological forces; and, lastly, the character of the intermediary distending body, the blood, for transmitting such energy—we are not surprised that, when a morbid action, especially of an acute obstructive character, is once inaugurated in the pulmonary capillary vessels, it should go forward to a speedy consummation.

1. Of the delicacy of the vessels in which the lesion we are considering occurs, it is needless to say they are capillaries, and have a structure accordingly. Their walls, as described by Gray, "are exceedingly thin," as they must be for the rapid and adequate performance of their especial function; they lie immediately beneath the delicate pulmonary mucous membrane upon the alveolar walls, and, with the connective tissue, make up the thin alveoli septa. In the alveolar structures they form a very close network, the pulmonary "plexus being one of the closest which occurs in the human body" (Kolliker). 2. These vessels, unlike others of their class—the cerebral only approaching them in this respect—are almost entirely without structural support, especially against extreme distension by a morbid action; for which anatomical reason, I may say, this special pathological process is of possible occurrence. Whereas other capillaries run through structures more or less solid, which sustain them when acted on by a too greatly distending intra-vascular pressure, these capillaries are suspended, so to speak, by the least possible amount of elastic connective tissue adequate for the purpose, and are bounded by air-spaces only. It will at once be appreciated that these vessels, being delicate, and not being restrained by direct support, also being unconfined by adjacent structures, and having, on the contrary, every liberty to expand into the surrounding air-spaces, may be readily and easily distended beyond their power to recover unaided when sufficient pressure is made within them.

3. These vessels constitute, as regards the entire circulatory apparatus, its weakest portion. Their place is very properly termed the locus minoris resistencia of the entire vascular system. This is so not only for the anatomical reasons given above, but because the position is, of all others, most exposed to the concentrated energy of the physiological circulatory forces. They form a short and, as we have seen, weak segment of the concentrated portion of the circulatory system of the great vessels whose walls are of great strength, and through which the blood flows with an aggregated volume and force. As we approach this region, the vessels, considered individually, not only become more powerful, but the circulatory forces become potentially and correspondingly aggregated.

These forces, normally, and at all times, especially when there is a large volume of blood to act upon, are derived from (1) the action of the left heart (not potent when the arterial volume is reduced); (2) capillary action (and in the genesis of this malady I claim that the normal capillary forces are greatly augmented by cutaneous spastic contraction); (3) lateral pressure resulting from muscular contraction; (4) right cardiac action; and (5) respiratory action. Muscular contraction probably does not form an important factor of the developed force in this process, as the cause is not active; but right cardiac action, and the respiratory movements, the former being accelerated while the latter are repeated with especial rapidity and effectiveness, are very potent, and the more so as their action is very near and direct. At any rate, the power which can be developed by these circulatory forces, especially under an excited action throughout, is immeasurably great in comparison to the resistance which can be offered by the pulmonary capillary segment when the circulatory forces become active and the blood becomes aggregated. Lastly, the character of the blood as an intermediary distending body renders it, in a particular sense, an effective agent both for the transmission of the force created and the production of the lesion which results. The characters which render it effective are its
incompressibility, its capacity for free action to regurgitate and make equal pressure in every direction and upon whatever point may restrict it, its hydrostatic capacity for transferring without loss any energy which is communicated to it, its quality of reaction whereby the potentially least resistant portion of its confining vessel is caused to yield first before an adequate pressure, and, lastly, its physiological tendency to circulate through the lungs. Furthermore, this fluid transmits the force imparted to it more potentially on account of venous valvular action, which, when a stress of force is applied laterally, prevents regurgitation and compels each venous streamlet so acted against to move forward directly upon the heart and lungs.

From these sources, and for these reasons, but especially on account of the aggregate sum of energy which may be developed by the physiological forces and transformed into pressure (rendered most effective by the anatomical structure and vascular arrangement), on the one hand, and, at the utmost, the comparatively feeble resistance which can be made by the affected capillaries on the other, functional insufficiency of these vessels and the immediate sequence of such a result, obstruction (first passive, afterward mechanical, due to a blocking of the capillaries), progress and extend very rapidly when once the process of insufficiency is initiated, and until checked by developing forces and counteracting conditions.

While the first result of an obstruction of the blood due to capillary insufficiency (after a passive filling of the atonied vessels has been accomplished) is regurgitation and deflection of the rapidly accumulating blood into lateral channels—into collateral capillaries (rendered easy by the nearness of the capillaries to each other [already given], and their frequent anastomoses), causing the production of a more extended insufficiency and obstruction as set forth—the second result of this pathological condition, accumulative obstruction conjoined with the continuing organic efforts of the system to circulate the blood and thus increasing pressure, is the creation of a further insufficiency—now anatomical of the capillaries first affected. This result has been noted in the context as the second essential event in this developing process. It occurs after obstruction from functional insufficiency has become somewhat extended in advance, and, therefore, collateral relief for the obstructed blood has been cut off; when the resulting pressure from the continually incoming, increasing blood, and from the action of the now excited and thence circulatory forces conjoined, is direct only, and felt most by that portion of the confining vessels least capable of making resistance, which has the weakest walls, namely, in the already affected, distended, and atonic capillaries.

This anatomical insufficiency is such a condition of these vessels as permits the escape from them, under the existing pressure, of such of the constituents of the blood as we shall see form the pneumonic exudation, and is the result of that degree of intra-capillary fullness and stretching from pressure direct and by accumulative blood action as is adequate to form minute stagnata, retiform openings, or endothelial (mural) separations, larger or smaller, through their walls.

That anatomical insufficiency and exudation as its consequence, and the consequence of a continually augmenting blood pressure, do result in this manner, is evident partly from facts already given in regard to the delicacy of the capillary walls (said to be only of an inch in thickness, and originally to consist of an endothelial-cell envelope), their unsupported anatomical condition, and the relative disproportion of the applied or potential force to the possible resistance these capillaries can offer to prevent such a result. The elastic nature of the capillaries and of the connective tissue which supports them anatomically, and the absence of solid, confining, supporting, and resisting structures about them, favor their easy and extreme distension; their delicacy of structure—extreme thinness—especially favors their structural separation by an adequate intra-vascular and active pressure. ("The capillary wall is elastic, extremely thin, and permeable. By virtue of these qualities, it may allow the passage of a leucocyte or colored globule through its substance without suffering a permanent breach of continuity." Wendt: Satterthwaite's "Manual of Histology," N. Y., 1881, p. 148, gives pertinent evidence upon this point.) And the great disproportion of the distending force, which is applied or brought into action to create this condition, over the possible resistance of the capillaries, makes this result a foregone conclusion.

But, as further illustrating the competency of these dynamo-physical causes to produce an expressed exudate, as set forth, I would refer to the efficient aid afforded by the respiratory movements in producing the necessary pressure to cause the structural lesion required for the result. These movements not only aid in causing exudation, but complete consolidation of the pulmonary structure, which event is, without doubt, principally due to the rapid dilatations and contractions of the lungs as they occur in this malady. This effect of the respiratory movements, acting upon and through the obstructed aggregated blood—first causing extreme distension of the helpless capillaries; second, their structural insufficiency; and, third, exudation until the adjacent lung structure is packed to its full distension—may be explained by comparing the result of such movements to the action of a rack and catch, of a bellows, or of a compression pump. It is a forcing action like the last referred to, in which the via a tergo of the afferent current constitutes a valve—preventing regurgitation—when the compression of expiration acts laterally upon the blood, which is received into the lungs with expansion or inspiration. Therefore, with expansion of the lungs the blood rushes in, on account of the suction created, and because it is driven forward by afferent pressure, and completely fills the space created; and when contraction of the lungs immediately follows, this advanced fluid being prevented from regurgitating by the via a tergo of the afferent pressure as set forth, acting as the bellows valve, is driven or forced forward into the distending capillaries until the result claimed—their extreme distension, structural or anatomical, insufficiency, exudation, extravasation—occurs, and consolidation is completed. The respiratory movements, in addition to the sum of the remaining circulatory forces, are
evidently quite competent to force the results as set forth. But, as still further favoring the results of circulatory force to produce the pneumatic exudation, I may refer to two other physiological facts which have a bearing upon the point—one having reference to the blood, and the other to capillary action. Of the latter, that vessels of their class, by their osmotic quality, favor such movements through their walls, and that especially when atomic they readily permit, in degree, both exudations and extravasations. Of the former, by virtue of the motility of all its elements—fluid and solid—it naturally and easily escapes from the capillaries, especially if these vessels are lacking in tone, by diapedesis.

That pressure, favored by the anatomical conditions and physiological potencies set forth, through a created structural insufficiency of the capillaries (also a prior result of obstructive and direct pressure), is the cause of the pneumatic exudation, is further evident from the fact, as we shall see when we come to an analysis of the exudate, that, histologically, it is comprised simply of blood elements; and, lastly, as rendering this last point more conclusive, it is evident from exclusion. The only other possible cause that could result in exudation is an inflammatory action, which I have shown, and, in my opinion, most conclusively so, is not present in this process as an essential cause.

For the reasons given, therefore, I hold it is shown that a direct blood pressure—which remains and increases by augmentation of the effluent blood volume after collateral relief for the accumulating blood is cut off, aided greatly by the forcing and packing action of the greatly accelerated respiratory movements, and rendered possible by the delicacy and anatomical environment of the pulmonary capillaries—is the cause, first, of the structural insufficiency of these vessels, and, second, of exudation.

It is well to remark here that with exudation begins the conservative action of this pathological process, which action, when completed, determines the well-recognized cyclical character of acute pneumonia—hitherto not explained. This is most beautifully and clearly shown in the varied results of this far-reaching event, which I now proceed to set forth.

The effects of exudation, which begins to pour forth with the least degree of created anatomical insufficiency, and closely follows in the wake of preceding events, have already been classified as extra-vascular, general intra-vascular, and local intra-vascular.

The most apparent extra-vascular effect is the consolidation of the involved lung structure. This consolidation varies in extent, as we shall see, more or less in every case of the disease; it may amount to the fraction of a lobe, a lobe, an entire lung, or even be of greater extent; portions of both lungs may become involved.

The extent of consolidation in each case depends, first, upon the degree of the predisposing asthenia of the pulmonary capillaries or of the existing vaso-motor asthenia; second, upon the degree of blood pressure, and the rapidity of its development and action upon these vessels. The degree and rapidity of the resulting pressure again depend upon the existing volume of the systemic blood, and also upon the irritative character of the idiopathic organic reaction set up on account of the functional interference created. As governing pressure, I have referred in the context to the fact that pressure and volume, relative to local conditions, are equal; hence where the general volume is great, disturbances may create greater and more disastrous pressure than where it is correspondingly small. Again, where the vital reactions from irritation are considerable and rapid, local disturbances of blood pressure will be more quickly created, and will be more potent to cause more extended results than where reaction is inconsiderable. Hence is explained, in a general way, the more frequent occurrence of a quickly formed and extensive consolidation in young, full-blooded subjects than in the aged or in the depraved, where the circulating volume of systemic blood is lessened.

It must be clearly understood, also, with regard to the mode of consolidation, that it is not the result of a widespread, evenly progressing, general action throughout the area of the lung structure which comes to be involved, but that, on the contrary, it is an aggregated result of many separate consolidations, each of which is complete in itself; and also that, in general, these consolidations are not of strictly contemporaneous formation, but that each one is or may be developed just prior or subsequent to the others about it, excepting where, from an extensive, sudden, and adequate pressure, a large area of capillary vessels becomes insufficient at the same moment, or extension is not developed by an immediate collateral circulation, but by more extended action.

These individual consolidations, coagulations—known pathologically as "pneumonic granules"—result from the coagulation and molding of the exudate as it is received into the extra-capillary and terminal pulmonary air-spaces as it escapes under pressure from the hyperdistended, now anatomically insufficient, vessels.

As the action by which a single terminal space in the lungs—consisting, as it does, of an alveolus, surrounded irregularly with air-cells, and of the entering, ending bronchioles—is filled with the solidifying exudate represents the process of consolidation throughout the area affected, so a study of the effects of exudation in a single space will more clearly set forth the results of a total exudation and its solidification, or the aggregate effects of the unnumbered separate exudations and consolidations which occur in any single process.

Before proceeding with such study, however, it will be well to fix in the mind two facts—first, that the terminal air-spaces mentioned, so far as this exudation is concerned, are practically separate from each other; and, second, that they have a very small holding capacity. Although the alveoli are connected anatomically through the branching bronchioles, yet, as the pneumonic exudate does not extend from one to another through these tubes, but solidifies or coagulates at once, and just within their open mouths, the cavities into which the exudation is poured are to be regarded as distinct from each other.

The capacity of these spaces, even when they are distended to their utmost, is but slight, as we shall see from
their measurements. According to Gray ("Descript. and Surg. Anat."), the terminating bronchial tubes have a diameter of from $\frac{2}{3}$ to $\frac{4}{5}$ of an inch; the alveolus, or intercellular space, is not larger, though less regular, and the air-cells which surround it are only from $\frac{1}{3}$ to $\frac{1}{4}$ of an inch in diameter. The depth of an alveolus is about $\frac{1}{2}$ of an inch. These spaces are larger at the circumference of the lung and in emphysematous lungs, while they are smaller in the more central portions of an organ, and in the lungs of either young or undeveloped subjects. The cube of about $\frac{2}{3}$ of an inch, a very small quantity, will therefore nearly represent the average and distended capacity of a single space, and hence the minute size of a separate conglom— a "pneumatic granule," as stated—which, as we shall see later, may be readily perceived by the naked eye upon a torn surface of a consolidated lung.

(To be concluded.)

A SINGULAR CASE OF CONGENITAL MISPLACEMENTS IN A DOG.

History.—The patient was a full-bred cocker-spaniel, about three years old. It was brought to me for examination by two of my colleagues, one of whom had had charge of it. This gentleman looked upon the condition as being primarily that of sarcocele, with the secondary development of hydrocele. So far as he could gain any information, the condition had been noticed by the owner some three months. The cause which necessitated calling in professional attendance was difficulty in defecation, accompanied with much pain.

Diagnosis.—A subcutaneous movable tumor on the right side of the rump, partially in the perineal region, but mostly to the right of it; probably of a cancerous nature.

Status Praesens.—Body well nourished; general health good; right testicle not to be felt. The tumor was oval, about two inches and a half long and one and a half broad; on palpation, one felt a soft, yielding mass, somewhat like dough in consistence, occupying the superior part of the tumefaction. Aside from this, an elongated, somewhat flat and ovoid object could be felt, which could be moved in all directions. This object was looked upon by my colleagues as the missing testicle. At the time of my examination nothing indicating the presence of fluid within the sac of the tumor could be felt; but that the gentlemen were not mistaken in their diagnosis of its presence, at intervals, will be shown shortly.

Operation.—The operation was very successful, but the patient died. Some would probably be of the opinion, more especially in the veterinary profession, that it is poor policy to chronicle one's errors in diagnosis or surgery; but it is my opinion that the careful study of them is of fully as much benefit to one's self and others as reporting our successes.

Complete anaesthesia was produced by ether. On a second and very careful examination we saw no reason for changing our conclusion. A section of the skin being made, we were enabled to examine more critically the contents of the tumefaction. No fluid escaped from the sac on opening it. There were no adhesions between the internal wall of the sac and its contents. The dough-like mass was found to be mostly adipose tissue; the hard object was of about the size of a man's testicle, somewhat flattened, with a sort of line of demarcation, or indentation, indicating a nodular septum of tissue harder than the remainder of the body, which had a somewhat spongy feel. The surface of this object was quite rough and slightly nodulated. On its posterior-inferior surface one could feel a cyst-like appendage, which did not contain any perceptible amount of fluid. One could feel quite a number of apparently ligamentous connections between this object and the body. On further examination of the adipose tissue, one could follow it into a canal which extended into the abdominal cavity, along the course of the rectum. This canal would easily admit the first two fingers of a man's hand for their entire length. The fatty tissue was determined to be an omental hernia. On enucleation of the rest of the contents of the sac, we found the connections to consist of two white, hard cords, a flat, ligamentous-looking body, and several blood-vessels.

The cystoid attachment to the tumor was conjectured to be the bladder, the two white round cords were taken to be the ureters, and, on catheterization, the ligamentous attachment proved to be the urethra, showing our conjecture to be correct as to the presence of the bladder.

The animal having suffered a great deal of pain in defecation during the preceding two weeks, in all probability from a loop of the rectum getting into the canal previously mentioned, and the future life of the patient promising to be burdened with still more suffering, it was thought best to continue the anaesthetic until death was produced.

Further examination revealed the termination of the penis at the angle of the ischium, where it was lost in its muscular adhesions; no part of it extended over the arch into the abdominal cavity. The urethra and two blood-vessels extended in a direct line, posteriorly, to the tumor, which was the hypertrophied prostate gland. The two other vessels connected with the latter, and the ureters, came out through the canal previously mentioned. The missing testicle was found in the external inguinal region, atrophied and buried in adipose tissue.

On opening the abdominal cavity, the right kidney was found to be floating, the vessels being six inches in length; all adipose surroundings were wanting. The other parts were normal. The presence of the bladder in the sac will explain the appearance of water, at times, to my colleagues; but no one seems to have noticed any variation in the external size of the tumor, which must certainly have taken place. The increase of the amount of the omentum within the sac and the continued enlargement of the prostate will explain the gradual increase of the tumefaction in size. The long hair on the parts would sufficiently explain the reason of its not being recognized earlier, or until the difficulty in defecation was noticed.
CLINICAL REPORTS.

NEW YORK HOSPITAL.

CLINICAL REMARKS BY ROBERT F. WEIR, M. D.

September 29, 1883.

Gouty Tumor of the Heel.—Traumatic Destruction Synovitis of the Foot; Disease of the Metatarsal Bones; Failure of Excision; Amputation of the Leg.—Necrosis of the Inferior Maxilla; Secondary Operation.

Gentlemen: The patient upon whom I operated ten days ago for removal of a tooth from the left bronchus recovered from the operation without an untoward symptom, and has left the hospital cured. A week ago to-day I operated upon three patients for tight stricture of the urethra, in two instances situated just anterior to the triangular ligament, and in the other in the anterior portion of the urethra, the operation being that of division, so as to allow of the passage of a No. 32 or 34 sound. After the operation, all these patients were given five drops of the tincture of aconite, with an eighth of a grain of morphia, and then three drops of aconite and one sixteenth of a grain of morphia every few hours. In one of the cases—not that of the patient, however, with previous nervous symptoms—two or three violent chills took place, and the temperature ran up to 106° F. That patient had several years ago had division performed, and then had a series of chills, and was for a while quite sick. Having received quinine on that occasion, he requested that it be given in addition to the aconite and morphia in the present instance. It was given, and, whether for that reason or from the element of time, the temperature soon fell. Yesterday all the patients were doing well. The temperature rose above 102° F. for a little while in one of the other cases also. I confess to some skepticism in regard to the efficacy of quinine in controlling the temperature after operations upon the urethra. This view is supported by the observations of Malherbe, a French surgeon. My rule is not to pass the sound after the operation until the slight elevation of temperature which we may expect after almost any incision had entirely passed away, and then to begin with a lower number than that to which the division has been carried—say No. 26—and occupy two or three sittings, one or two days apart, in running from this number up to 32 or 34, as the case may be. No chill followed the passage of the sound yesterday.

The first patient upon whom I shall operate upon to-day is a physician of middle age, a subject of gout. Two years ago he noticed a swelling over the left heel. This has grown slowly in size, and occasionally a small amount of whitish fluid exudes from it. The rubbing of the shoe causes some irritation. The growth has now reached the size of a walnut, and you observe, upon section, after its excision, that it appears, from its light gray color and grittiness, to be composed of the trate of sodium. All bleeding having been checked, the foot will be dressed with gauge impregnated with a solution of bichloride of mercury, and healing be allowed to take place by granulation.

The second case is that of a man forty years of age, who entered the hospital on the 29th of July, 1883, having four months previously been struck on the foot by a falling stone. Inflammatory action took place, resulting in an abscess with several openings, through which, at the time of his admission, probes could be passed down to softened bone. Most of the trouble seemed to have been along the line of the sculptoid articulation. On rubbing the tarsal bone together, crepitus was elicited, indicating that the cartilaginous surfaces had undergone disorganization. The condition being due to traumatism, it was hoped that it could be the more effectually treated by excising the dead bone, and for this purpose, on the 8th of August, the patient was placed under an anesthetic, the sinuses were freely opened, and a large amount of fungous granulations was removed, together with a part of several of the bones of the tarsus, which were the seat of necrosis. Free drainage was established through a large rubber tube. This attempt to save the foot failed, however. Considerable inflammatory action continued, and, while during the past two weeks there has been much less local than general trouble, there has been unpleasant constitutional implication indicated by elevation of temperature, etc., and septicaemia is threatened. The temperature rises every night to between 100° and 101° F.; but there is not much sweating, and no diarrhoea. I shall amputate the leg a little above the middle, making a flap operation, and using the Esmech bandage, which will be left on until after the completion of the dressing of the stump, as advised and practiced by that surgeon. The dressing, as you see, consists of pieces of sublime gauze, a roller bandage, a peat pad, and outside of all a rubber bandage. This latter will be kept on for an hour, but the rest of the dressing will be left on for eight days or two weeks, unless there be some indication for its removal. To avoid the change of dressing which a rubber drain demands at the end of a few days, an absorbable bone tube will be used for this purpose.

The third case is one of necrosis of the lower jaw, in a girl twenty years of age, who entered the hospital on the 8th of July of this year, giving the following history: Six months previously she had trouble with her teeth, resulting in pain and swelling about the lower jaw. The teeth were drawn, but the pain and swelling did not abate, but rather increased in severity. Finally an abscess developed, which opened externally and also into the mouth. Through these openings, which were surrounded by dense, branny, swollen tissue, dead bone could be felt. No special treatment was instituted except to keep the parts clean with disinfectant lotions, but the patient has continued to suffer a great deal of pain; occasionally one of the openings closes, when the swelling increases, and then a fresh discharge of matter takes place. Very small pieces of bone have been observed to come out on two or three occasions. On introducing the probe, the patient not being under the influence of an anesthetic, I was able to feel dead bone at the angle of the jaw, both on the external and on the internal aspect. In flat bones the dead portion does not separate as soon as in the long bone, and we are therefore often uncertain when to interfere surgically; but in the present case, and at the present stage of the trouble, we feel justified in cutting down and removing any dead bone that may be found. You will observe that, having broken down the involucrem, I have been enabled to remove the portion of dead bone, which consists of the angle of the jaw, being fully an inch long, and involving the entire thickness of the bone. A drainage-tube will be inserted, and a gauze dressing applied, as in the two former cases.

Removal of a Foreign Body from the Pleural Cavity.

Gentlemen: The first patient upon whom I present to you to-day is a man, twenty-eight years of age, who entered one of the medical wards on the 29th of August, more than three weeks ago, suffering from symptoms of pleurisy. The pleural cavity rapidly filled with fluid, and on the seventh of the month aspiration was resorted to. A large amount of nearly clear fluid was withdrawn, but the temperature rose afterward, and the symptoms in general pointed to the formation of pus in the pleural cavity. This supposition was verified by withdrawing a small amount of that fluid with the hypodermic needle. Three days ago a large
trocars and canulae were introduced, and a number of ounces of pus were withdrawn, the carbolic spray playing during the operation. In the case of another patient, upon whom the operation was performed at the same time, the outer tube, which was quite a large one, was allowed to remain in the opening, and the man has since done perfectly well. In the case of this patient, however, as the cannula was imperfect, I inserted a piece of rubber catheter through the tube into the pleural cavity, prior to the withdrawal of the latter, in order to secure perfect drainage, and to avoid the chafing which sometimes takes place from the rigid or sharp end of a metallic tube. In order to guard against the possibility of the suction force of the air entering the pleural cavity drawing the tube within, I had passed a suture through the tube and the skin on either side, thus securing it perfectly, but I was not aware of the fact that the catheter, though never before used, had been for some time in the hospital. Though flexible, it had deteriorated from age in a way that I will shortly explain, and was liable to break, which it afterward did, and entered the pleural cavity. This was discovered the next morning, after fifty three ounces of pus had drained into the antiseptic dressings used. This weakness in rubber tubing, while common to all vulcanized goods, is often met with in the red rubber, for I have been informed that, in order to make catheters smooth and polished, sulphide of antimony is used, and an excess of this element can frequently be recognized in a dusty layer, which in time exerts a deleterious influence upon the rubber, destroying its elastic qualities. This fact should also be remembered in connection with catheterization of the bladder, and a patient, when given a rubber catheter to pass upon himself, should be instructed to always buy two at a time, in order to guard against an accident taking place in the bladder similar to that which has occurred in this man's pleural cavity. I may add that the elastic quality of rubber is better preserved by keeping it immersed more or less in pure water or in weak water of ammonium. Since this accident has occurred, I have learned, in conversation with several of my professional friends, that a similar one has taken place four or five times in their experience, the tubing escaping either directly from the hand of the surgeon into the pleural cavity, or afterward from being imperfectly secured to the thoracic walls. In each instance the foreign body was successfully removed and the patient recovered, and the pleurisy did not seem to have been aggravated by the accident; on the contrary, the cure seemed to have been hastened thereby—that is to say, that a free opening was beneficial. In connection with the use of rubber catheters in urinary surgery, I recall the case of a man who once came to me in great distress, more of a mental than of a bodily nature, he having passed, while at Long Branch, a rubber catheter, as he had been in the habit of doing, and, on trying to withdraw it, found that a part remained behind in the posterior portion of the urethra. Retention fortunately was not present, as the urine flowed continuously through the catheter, the outer end of which was just outside the triangular ligament. I withdrew the piece without difficulty, but have since been in the habit of instructing my patients to observe when the catheter begins to swell, which is an indication of its weakening, and to discard it at once. You will observe that, in the case of this patient, the intercostal space is large, and I have been enabled to cut down into the pleural cavity, going through a considerable thickness of tissues, and, failing to find, as I hoped, the catheter in the track of the puncture, I have therefore opened the pleura widely, and have inserted a long bent dressing forceps, and with very little difficulty have seized the piece of tubing and withdrawn it. It is nearly four inches in length. Had the intercostal space been as narrow as in some patients, it would have been necessary to remove a portion of a rib in order to obtain sufficient room to hunt for the foreign body, and to extract it; in that event, of course, the intercostal artery would be divided, but this, I may say, is an accident which constitutes much less of a bugbear in the surgery of the chest than formerly. Bleeding may be easily checked with the hemostatic forceps. If you are not fortunate in the first seizure with this instrument, draw up the parts with it in situ, and then, probably more easily, you can catch the artery and tie it. The method described by Dr. Abbe, in the "Medical Record" for February 18, 1882, an illustration of which you here see, is also very effectual in controlling the hemorrhage from this artery, and has been practiced with great satisfaction by other surgeons since. I have now introduced a piece of large and thoroughly tested black rubber tubing through the wound into the pleural cavity, sewed the cut walls closely around it, passed a safety-pin through the tube, and, to make matters doubly sure, secured the safety-pin to the chest-wall by means of two threads and some sticking-plaster. To secure any possible advantage which may pertain to the carbolic-acid spray, two of these have been made to play over the wound during the operation. An antiseptic pot dressing, under which a rubber bag is placed containing sublimated sponges, for the purpose of absorbing the escaping purulent fluid, has also been applied.

October 6, 1882.

Pneumothorax.—Thoracentesis.

Gentlemen: This patient, a male and an Italian, entered the medical wards of the hospital some days ago, giving a very imperfect history. He had been sick for about twenty days, dating from an exposure to wet. He had chills at irregular intervals, followed by fever and sweating. There was difficulty of breathing, with severe cough and but little expectoration. The liver and the spleen were found enlarged. The patient was transferred to the surgical ward for an operation for pyo-pneumothorax of the left side of the chest, of which there were the usual physical evidences, such as the metallic tinkling, splash of succussion, etc., being present, and the presence of pus was, furthermore, positively determined by the introduction of the hypodermic needle. I shall now cut into the pleural cavity low down, at a point below and back of the axillary space, in order to secure free drainage. As a matter of safety, the carbolic-acid spray will be used, though not with the same security as in the previous case. About forty ounces of pus have been removed. I now introduce a large and strong rubber drainage-tube, made fast by a safety-pin, and apply a thick peat dressing soaked in the bichloride solution, as in the other case. The patient's general condition is low, and what the final result will be can only be determined with time; it must be remembered that there is a possibility of the lung perforation being due to tuberculosis, though the evidence of such is not found.

October 13, 1883.

Opening of the Knee Joint for Supposed Movable Cartilage.—Fatty Tumor of the Shoulder.—Hydroucele Injected with Pure Carbolic Acid.

Gentlemen: The case before you is one of inflammation of the knee joint of long standing, occurring in a man twenty-nine years of age, who has had syphilis, although antisypiliferous treatment has had no apparent effect upon the joint affection. The disease began, without any previous injury, two years ago, in the form of a swelling of the left knee, unaccompanied by pain. After a time, however, the patient noticed that once in a while, when walking about, the knee was seized with a feeling as if the ligaments were put upon the stretch, which caused severe pain, notably on the inner side of the joint. He received treatment at the Chambers Street Hospital, where it was recognized that there was considerable fluid in the joint,
and elastic bandages were applied, which caused considerable absorption. When the man presented himself at my clinic at the College of Physicians and Surgeons, a few days ago, there was tenderness about the knee, with considerable general distension of the whole joint, and a marked bulging on the posterior aspect of the limb over the inner hamstring, which evidently contained fluid. It was uncertain whether this swelling communicated with the interior of the joint or not, but, on the whole, the case appeared to be one of so-called hydrarthrosis. After considerable manipulation, there was then discovered at the inner side of the patella a hard movable body, which by pressure slid under the ligamentum patellae. I told you at that time that such loose cartilages in the knee joint as this appeared to be were due usually to one of three things: First, from inflammatory enlargement of the fringes of the synovial membrane lining the joint. These may either remain attached or float loose after being detached and increase in size. Or, secondly, an injury might possibly have caused a piece of the semilunar cartilage to become detached. Or, thirdly, a blood-clot, the result of an injury, might become so far organized as to act as a foreign body. Of these three common causes, the most frequent one is the organization and detachment of synovial fringes. This complication is more likely to occur in the knee joint, but it also sometimes occurs in other joints of the body. Sometimes the detached fringes exist in considerable numbers, especially in cases of rheumatic arthritis. There is no history of injury nor of rheumatism in this case. Whether the pain which sometimes occurs while he is walking about is due to a loose body becoming caught in the joint, I am unable to say, but the suffering he experiences is far less than is usual. Some patients learn, when this accident occurs to them, to set the obstacle free within the joint by forced flexion or extension, after which they can continue their journey. The origin of this body in the present case can not be positively settled until the joint has been cut into, if, indeed, it can be done then.

An incision was made over the supposed cartilage near to the inner side of the patella, but, on opening the joint, the mass that appeared in the wound was not hard nor white but soft, fibrous, and of a brownish hue; it could be drawn nearly an inch out of the joint with a pedicle of increasing thickness. To explore this, which was a novelty to all the surgeons present, the wound was enlarged. The growth (I) could be traced by the finger to run across the joint under the ligamentum patellae and between the femur and tibia for some distance. The question arose whether this might be a neoplasm, one of the rare fatty tumors found occasionally in joints, or whether it was an abnormally enlarged subligamental fatty tissue. Opinions were divided in the consultation as to the course to be pursued: whether to cut across the joint and to remove the mass, or to tie up the piece already seized and somewhat torn by traction, and to drain the wound after washing it out thoroughly with the sublimate solution. The latter course was decided on, though considerable difficulty was experienced in satisfactorily washing out the poultice over the internal hamstring, which communicated with the joint cavity. The parts were then thoroughly enveloped with an absorbent dressing of wood-wool, and the leg strapped to a Volkmann’s splint, enameled to avoid its becoming contaminated by absorption of the discharges.

With regard to the dangers of removal of loose cartilage from the knee joint, before antiseptic methods were employed, out of one hundred and sixty-two cases operated upon there were about twenty-eight deaths. In thirty-two cases in which antiseptic methods were employed not a single death occurred. It must be remembered, however, that this patient has undergone a more severe operation than the simple one of removal of a loose cartilage from the knee; I have seriously invaded the joint, and the final termination must be more or less doubtful; there will probably at any rate be more or less stiffness of the leg. You will observe that instead of using the spray I have operated in this case under an almost continuous flow of the bichloride solution.

I have been requested by Dr. Markoe, who has been called away, to remove for him a fatty tumor from the shoulder of a woman of about thirty years of age. The tumor is situated just beneath the skin, which it has thrown into more or less distinct dimples, leaving no doubt as to its real nature. You will observe that it has been removed with perfect ease, a drainage-tube inserted, and the wound closed up to the tube with a continued catgut (Koche’s) suture. The tumor is of about half the size of the fist, and is composed of lobules of fat. Such growths do not as a rule return after removal.

The next case is one of simple hydrocele, which has been tapped on several occasions, the fluid reaccumulating after a time. The cause for the condition can not always be determined, especially in the aged; in younger persons it is often due to the irritation of the tunica vaginalis, from a testicle damaged, from gonorrhoea, or from an injury. In this man’s case the hydrocele followed a kick upon the stomach by a horse. The treatment which I first adopted in these cases was the usual one of throwing tincture of iodine into the sac of the tunica vaginalis, having first evacuated it of the hydrocele fluid. I early learned, acting upon the suggestion of my preceptor, Dr. Buck, to augment the amount of inflammation produced by the iodine by rubbing the tissues together for several successive days after making the injection. Statistics, however, showed that in a considerable percentage of the cases thus treated the cure was not permanent. In fifty-four cases collected by Osborne, a recurrence took place in eighteen. After antiseptics came into vogue I operated in about thirty cases, adopting the method of Volkmann, of incising the hydrocele its full length and stitching the tunica vaginalis to the skin, inserting a drainage-tube and partially reclosing the incision. This method was very effective, but the procedure was rather heroic, required an anaesthetic, and confined the patient to bed ten or fifteen days afterward. The method by injecting tincture of iodine had also been often attended by such local and general disturbance that the patient had to remain in the house from three to ten days. I then made use of a twenty-per-cent. solution of carbolic acid, throwing an ounce or two into the tunica vaginalis repeatedly through the cannula after withdrawing the hydrocele fluid; a drainage-tube was inserted through the cannula before the latter was withdrawn, and antiseptic dressing was applied. This treatment caused no pain, and was attended by very good results, but the degree of inflammation was not always sufficient; hence, lately following the example of Levis, of Philadelphia, I have been in the habit of injecting from half a dram to a dram and a half of pure carbolic acid, having first emptied the sac of the hydrocele fluid. Scarcely any pain attends the operation; it is very effectual, and the patient is able to attend to his business the next day. I have had an experience of nearly fifty cases treated this way, and in but two has any extra inflammation occurred. No cases of poisoning were met with. There is no doubt about the diagnosis in the present case, the form of the tumor, the fluctuation, and the translucency, all being undoubted evidence of hydrocele. You should remember, when examining the tumor by transmitted light, that the testicle, in accordance with the laws of refraction, appears smaller than it is in fact, and thus avoid puncturing this organ with the trocar. I have thrown about half a dram of pure carbolic acid into the tunica vaginalis, after having let the water escape through the cannula. This is allowed to remain in the cavity, and no dressing is applied.
THE NEW YORK MEDICAL JOURNAL,  
A Weekly Review of Medicine.

NEW YORK, SATURDAY, NOV. 3, 1883. 

THE PRELIMINARY EXAMINATION AND THE GRADED COURSE. 

During the past few years there has been a disposition on the part of our leading medical colleges to a progressive advance in methods of teaching, and it must certainly be acknowledged that a good deal has been accomplished in this direction. Twenty years ago the object aimed at, almost without exception, was to indoctrinate the students with the lecturers' personal views, and, in so far as argument was brought to bear at all, it was rather rhetorical than demonstrative. Now men are taught methods of investigation; they are taught to avoid seizing upon the plausible in theory, and, in fact, to regard all theory, save that which has been proved beyond question, as only a convenient scaffolding to serve a temporary purpose. Consequently, the medical students of the present time are educated in the real sense of the word, and not merely imbued with this or that doctrine. 

Under this new state of things, the student soon finds that, except in cases of rare natural aptitude, he needs all the aid that can be drawn from previous drilling in modern methods of study. If he lacks that resource, the chances are decidedly against his taking a creditable stand in his class, and oftentimes against his being able to pass the final examination. It is chiefly on this account, we think, that a preliminary examination is of service. It is a simple test of the candidate's fitness to divert his mental activity into special fields of study. In other words, it is a sort of act of mercy to the student, enabling him, at the expense of some mortification at the outset, to avoid the deeper and more far-reaching disappointment that would be his were he to fail at the last after a long struggle with the odds against him. We are unable to see that the preliminary examination answers any other good purpose. It surely does the college no good, and it certainly does not make its diplomas one whit more valuable. Still, its enforcement is to be commended, and it is to be regretted that colleges that are not endowed can seldom afford to dispense with the patronage which its tendency is to deprive them of. 

In regard to the graded course of instruction, there seems to be room for serious doubt if it will finally be conceded to be an advantage. Our impression is that it will be found to be the reverse. If a man has to study anatomy throughout his whole career, in order to achieve excellence as a surgeon; if chemistry and physiology, with all the rapidity of change that marks them, must constantly be called into requisition by the student of pathology; if materia medica and general therapeutics must support special therapeutics at every step—all of which suppositions we take to be indisputable—it is difficult to see what advantage is to result to the student from laying them aside so soon as he has once been able to pass an examination in them. To be sure, it facilitates the task of winning a diploma, since it divides the forces he has to contend with; but, far from giving him a better outfit with which to follow the practice of medicine, we are convinced that its tendency is quite the contrary. Moreover, we are unable to discern any harm in teaching clinical medicine and surgery to the novice. No one dreams of insisting upon a knowledge of descriptive anatomy before regional anatomy is taken up. In all departments of scientific teaching the acquisition of facts should go hand in hand with their application. It is only in this way that principles can really be elucidated. Besides, no faculty of the mind stands more in need of training than that of observation—it should be trained from the very outset. By all means, let first-year students see all the cases of disease they can. It is better that they should draw erroneous impressions, which they will readily correct as their study advances, than that their opportunities of learning the case with which error is fallen into should be put off to a period at which their ideas of their own acquirements have become so large that they rebel against confessing to themselves that they can be wrong. 

While we regard the graded course as a delusion, however, we believe that those colleges that have adopted it have done so in consequence of a genuine conviction that it was a step in the right direction. We are quite as much convinced, nevertheless, that the three great New York schools, together with the Jefferson College in Philadelphia, will not find in the long run that they have suffered, or that they have sacrificed anything of their pre-eminence, by declining to follow suit. 

THE FORM OF THE SKULL IN THE TWO SEXES. 

At a recent meeting of the Paris Society of Anthropology, M. Manouvrier summarized his observations on the relative form of the skull in the two sexes. He first sketched the prevailing opinion on the subject, remarking that Gratiolet recognized three cranial types—the frontal, the parietal, and the occipital—according to the relative development of these three cranial vertebrae. That author maintained that in children, as among the Mongolians, the typical form of the cranium was parietal, and that that type persisted through life in the case of women, while in men the type became frontal in the white races as compared with others. 

M. Manouvrier has been led to the conclusion, from experimental researches, that a general relation exists between the proportional weight and the form of the brain and of the skull. Contrary to the opinion generally entertained, he has found that the relative weight of the brain is much the greater in the female sex. From a study of several hundred skulls of French men and women, as well as from numerous data published by various authors who have studied the matter from diverse points of view, especially Broca, M. Manouvrier concludes: 1. That the feminine skull is of the frontal type, as compared with the masculine. 2. That the skull of a woman differs from that of a man especially by the lesser development of the parietal re-
gion, the seat of what is known as the motor zone of the brain. 3. That in women the occipital region is much more developed than in men, regard being had to the general cranial development, although relatively less than the frontal region. 4. That the vault of the cranium, as compared with its base, is greater in women than in men. 5. That, in proportion to the cranium, the face is smaller in women than in men.

These conclusions are founded on the following observations: The cubic capacity of the frontal bone, as examined in ninety-four frontals taken from the catacombs, is almost absolutely the same in the two sexes, whereas the total capacity of the cranium is quite different. The coronal angle is greater in women, and so is the frontal portion of the basis cranii, while the temporoparietal portion is smaller; in other words, the antero-posterior measurement of the frontal compartiment of the endocranium is greater in women in proportion to the total size of the skull from before backward. The breadth of the forehead is the same in the two sexes on internal measurement, the external excess in men being due to a difference in the thickness of the bone. In women the cerebral diameters are greater as compared with the facial diameters, with the length of the base of the cranium, and with the vertical diameter, the latter giving only the height of the middle of the vault. The first and second frontal indices of Broca and the fronto-zygomatic index (the proportion between the minimum frontal diameter and the facial bi-zygomatic diameter) are greater in women. The frontal part of the horizontal circumference, as compared with the remainder of that circumference, is the same in the two sexes, the parietal part being relatively greater in men, and the occipital in women. The frontal portion of the antero-posterior cerebral curve, as compared with the rest of that curve, is greater in women, and the frontal auricular angle of Broca is also greater, while the parietal auricular angle is smaller. In women the antero-posterior curve of the cranium and the antero-posterior diameter are greater as compared with the naso-basilars line, which marks the length of the basis cranii.

THE STUDY OF PSYCHIATRY.

The German Government having lately discussed the question of dropping the subject of the treatment of insanity from the requirements in the State examination, and having, it is reported, decided to omit that test, some of our German contemporaries very properly express regret at the fact. It is pointed out that the connection between a sick person's mental state and his bodily condition is sometimes so close that the physician in attendance would find a knowledge of insanity and its management of great advantage. This is notably the case with puerperal insanity, the victims of which are usually best treated at their homes. Indeed, the home treatment of almost all forms of mental alienation, for a time at least, is scarcely to be avoided, especially in districts remote from an asylum. To dwell upon the desirability of some degree of systematic knowledge of insanity on the part of the general practitioner under such circumstances seems so manifestly a work of supererogation that the wonder is that a government so progressive and so

THE REGULATION OF MEDICAL PRACTICE AND THE PLEA OF PERSECUTION.

An individual who styles himself a "magnetic physician" has lately been writing letters from Boston to the newspapers, in which he waxes fierce in denunciation of the New York law regulating medical practice. We have received proof-sheets of two of these letters, written to the "Banner of Light" and to the "Saratoga Sentinel," for which favor we presume we are indebted to the author. Stripped of their wordy ferocity and their inconsequential attempts at argument, the letters in question assume that the law in force in this State, together with laws of the same general purport elsewhere, is a device on the part of non-sectarian physicians to oppress the medical sects.

Every quack in the land is crafty enough to see that this spurious plea is almost the only one likely to touch the popular heart, and that, aside from downright "influence," it is all that can be relied on to bring about a repeal of the laws already in existence, or to prevent the enactment of like laws in States that now have none, relating to the practice of medicine. And there is great danger that this plea will prevail. Of course, it is utterly unfounded, as any one may assure himself by a perusal of the statutes in question. There is no law in force in this country that discriminates against any sort of medical practice, and there never will be. The legislation thus far obtained by the medical profession requires only proper guarantees that practitioners of medicine are persons who can show evidence of having received a fair medical education; it does not concern itself with their peculiar theories or modes of practice.

Of course, all this is well known to our readers, but it is not known to the general public, and there is no little danger, consequently, that a sympathetic clamor will be raised that will have its effect on legislators. Were the facts of the case known to the people, the scoundrels who trade on the love of fair play that prevails everywhere among us would find their occupation gone. We trust, therefore, that our readers will
omitted no opportunity to present the matter in its true light, each before his own circle of acquaintances, to the end that no senseless clamor may prevail against the uniformity of legislation that there seems to be some hope of securing as a means of making the profession as a whole what it should be, and of protecting the community against the predatory incursions of traveling mountebanks.

THE NOTIFICATION OF INFECTIOUS DISEASES.

There is great reason to fear that the risks run by the community in consequence of the failure by physicians to report cases of infectious disease to the proper sanitary officers are not appreciated by many members of the profession. It is not alone that the value of our statistics is vitiated by reason of their being founded on incomplete returns—a consideration ample of itself to impel every conscientious practitioner to do his duty in this matter; but, in addition, it needs no elaborate reasoning to show that outbreaks of infectious disease often grow to dimensions that make them practically unmanageable, which, if carefully reported in their beginnings, might readily have been brought under control.

Our own Board of Health has never failed to urge this matter with due energy upon the attention of the profession, although it has judiciously refrained from pushing the punitive provisions of the laws under which it acts. In proportion as it has been discreet should its appeals be heeded. Our attention is called to the subject anew by the practical way in which its bearings are put in the last Annual Report of the Connecticut State Board of Health, a volume alike creditable to the board and to the State. It is pointed out that the closure of schools might often be avoided by measures looking to individual isolation, with the double advantage of shielding the pupils against infection from their fellows and of keeping them away from other sources of infection during the hours devoted to study.

Some years ago, when boards of health were a novelty in this country, they may have shown a disposition to create unpleasantness in families afflicted with infectious diseases, but we are quite sure that that mode of behavior is a thing of the past, and that no physician now need hesitate to report a case under the apprehension that the patient or his friends will find the consequences disagreeable.

MINOR PARAGRAPHS.

THE HERO OF FIELD HOSPITALS.

The man in whom, while still but an assistant surgeon, Surgeon-General Hammond had the discernment to see the qualities to fit him for the exacting and responsible position of Medical Director of the Army of the Potomac is not likely to pass from the memory of those who took any part in the work of maintaining the organization of that army, or who were in a position to realize the perfection to which its organization was carried. But it is now verging on a score of years since that army was disbanded, and the number of persons to whom Surgeon Jonathan Letterman's achievements are personally known is getting to be limited. By preparing a memoir of Dr. Letterman, therefore, Surgeon Bennett A. Clements, of the army, has performed a service to the community, every member of which has a personal interest in the matter of army organization in case of another outbreak of war, as well as a graceful act in commemoration of a deceased fellow-officer. We refer to his paper published in the September number of the "Journal of the Military Service Institution," a copy of which, in the form of a handsome pamphlet, issued by Messrs. G. P. Putnam's Sons, we have taken great interest in reading.

EVOLUTION AND THE TREATMENT OF WOUNDS.

We have been much interested in a brochure* lately brought out by one of our occasional contributors, Dr. C. Pitfield Mitchell, in which he treats of the connection of the doctrine of evolution with the management of wounds. The work is scholarly and thoughtful, being in part an elaboration of the author's article, entitled "An Evolution Aspect of the Healing of Wounds," published in this journal rather more than a year ago. A thorough advocate of the doctrine of evolution, especially as expounded by Mr. Herbert Spencer, Dr. Mitchell yet avoids the temptation to fit facts to the law, but contents himself with tracing their points of contact. We commend the essay to our readers' attention.

THE "MEDICAL STUDENT."

Thus is the title of a new monthly journal, published in New York. The size of its page is about that of this journal. The first number, dated October, 1883, contains twelve pages of reading matter. The typographical appearance is creditable, and the first issue is embellished with a particularly good portrait of Professor William Darling. If medical students are really in need of an "organ"—and such seems to be the idea of Mr. William G. Mortimer, who is both the editor and the publisher—they are to be congratulated on having found one of such handsome appearance, and one that gives promise of containing much matter of interest not only to under-graduates, but also to practitioners.

THE NEW YORK INFANT ASYLUM.

On complaint of the asylum, and on the affidavit of Dr. Frederick M. Warner, Dr. Edward Bradley, Dr. George B. Fowler, and Dr. A. N. Bell, Judge Donohue has enjoined the Board of Health of the Town of East Chester from all further interference in the concerns of the asylum. This scarcely improves the status of the institution before the public or the profession. Last week we published a letter from Dr. William M. Polk, in which he stated that he had never had any official connection with the asylum, and now Dr. Paul F. Mundé asks us to announce that he has resigned from it.

LIABILITY FOR DOCTORS' BILLS.

A correspondent of the "Maryland Medical Journal" says: "Dr. Samuel H. Gump was sent for by Mrs. Harry Fisher to attend her nurse, who was sick at her place in the country. The nurse failing to pay the bill for professional services rendered, the doctor sent it to Mr. Fisher, who refused to pay it. Thereupon the doctor brought suit against Mr. Fisher, and the case was tried before Judge Duffy, of the Baltimore City Court, on October 20, 1883. The judge decided that Mr. Fisher was responsible for the payment for medical services rendered the nurse employed by him, the doctor having been sent for by Mrs.

Fisher, and that she had the right to make her husband responsible for such services, and that, having sent for the physician herself, her husband was fully responsible. Judgment was given the plaintiff for the amount of the bill and costs."

**NEWS ITEMS.**

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 30, 1883:

Yellow Fever.—A Pacific mail steamership arrived at San Francisco Wednesday morning, with three of her company suffering from yellow fever.

**The Cholera in the East.**—A reoccurrence of the epidemic has broken out in Alexandria, causing from five to ten deaths daily, and the disease is reported to have appeared at Mecca.

Small-pox.—One of the Cunard passenger steamerships reached this port on Wednesday, having a patient with small-pox on board. The affected person was isolated after it was known that he had the disease, and the vessel was allowed to come up to her berth after a short detention at the quarantine station, where she was fumigated.

**The Late Dr. Beverley Livingston.**—At a stated meeting of the New York Pathological Society, held October 24, 1883, the following tribute to the memory of the late Dr. Beverley Livingston was unanimously adopted:

The decease of our late colleague, Dr. Beverley Livingston, brings to the Pathological Society an uncommon sorrow. When, in the fullness of years, one of our number is called from our midst, the knowledge that separation must come at last and the pleasant recollection of completed labor reconcile us to our loss. But when we are deprived of the counsel of one who gave such promise of useful and invaluable aid, before whom there seemed to be a long and honorable career and an almost achieved reputation, our sorrow is deep indeed.

Dr. Beverley Livingston was distinguished by an earnest zeal, indefatigable industry, by love and devotion to his profession. While he gathered in the pursuit of practice some of the fruits which the latter yields, he gave an ample return by aiding, as an active co-worker with us, the advancement of science. Though his career was incomplete, the lesson of his life is none the less perfect. To have won the respect and esteem of his colleagues, to have been honored in the full discharge of his duties as a man and physician, is the reward which the memory of our late associate proudly and justly claims.

The New York Pathological Society presents this tribute to the worthy family of the deceased, in the hope that in it they may find a better consolation than in words of sympathy.

Signed
H. N. Heineman, F. Ferguson, E. L. Partridge, Committee.

**An Expulsion from the New Haven County Medical Society.**—At the recent semi-annual meeting, Dr. Francis Bacon moved the following resolutions, which were unanimously adopted:

Whereas, E. L. R. Thomson, a member of this society, is accused of the offense of criminally procuring an abortion, and was prosecuted therefor in the City Court, and, making no defense, was held in bond of $1,000 for trial in the Superior Court, which bond he has since forfeited rather than to appear for trial at the appointed time, hoping thus to escape further punishment, and thereby making virtual confession of the justice of the accusation; therefore, be it

Resolved, That he, the said E. L. R. Thomson, be, and hereby is expelled from this society.

Resolved, That this society, viewing with deep concern the prevalence of the execrable crime of fertilicide, a crime which strikes at the very roots of society, a crime equally shameful, demoralizing, and fraught with infinite dangers to the woman upon whom it is practiced, has seen with indignant regret the latest exhibition of folly in the administration of laws against this crime.

Resolved, That, in the opinion of this society, the conviction and adequate punishment at law of a conspicuous abortionist would have a stimulating and salutary effect upon the public conscience, now dulled and numbed by the sight of statutes condemned as a dead letter by the impunity of habitual malefactors.

The Cost of Public Charity and Correction.—The Commissioners of Public Charities and Correction estimate that $1,711,377.50 will be required to maintain the institutions under their care during the coming year.

The New Pharmacopœia.—The publishers, Messrs. William Wood & Co., announce that any person having purchased a copy of the United States Pharmacopœia of 1880, and desiring a list of the corrections made since its publication, can procure the same by sending a two-cent stamp to them.

The Veterinary Medical Society of the State of New York was organized last week.

The Paris Faculty of Medicine.—M. Jaccoud, formerly professor of pathology, has been transferred to the chair of clinical medicine, succeeding the late M. Lasègue. Candidates for the vacant chair of pathology were to be allowed until October 26th to present their claims.

Conviction of an Abortionist.—Mrs. Furlong, the Brooklyn abortionist, has been convicted on a charge of criminal abortion. An outline of the facts in the case was given in the journal several weeks ago.

**OBITUARY NOTES.**

**John Francis Gignoux, M. D.**—Dr. Gignoux died on Friday of last week, in the forty-first year of his age. The deceased was of French parentage, but we think he was born in this country. At all events, the greater part of his life was spent in New York and its immediate neighborhood, although he received his academic education in Maryland. He graduated in medicine from the College of Physicians and Surgeons, in the class of 1861. Before receiving his diploma, he served creditably in the United States Sanitary Commission, and after his graduation he spent two years as a member of the house staff of the New York Hospital. After completing his term at the hospital, he practiced medicine for several short periods in New York and in Monroe, Orange County, his professional career being interrupted a number of times by his embarking in business undertakings of various kinds. When seized with his last illness, he was in practice in this city.

Dr. Gignoux was a man of powerful build, and his death at the comparatively early age of forty is a surprise to those who have often admired his physique. His bodily vigor was fully
equalled by his mental capacity, and his qualities of heart were such as to endear him to all who knew him.

Alva E. Kemp, M.D., of East Douglas, Mass., died suddenly on Monday, the 29th inst., at the age of sixty-one. He was a member of the Massachusetts Medical Society, and was held in high esteem both as a physician and as a citizen. His death was due to disease of the heart.

Dyer Loomis, M.D., of New Berlin, N. Y., died recently, at the age of eighty-three. He was born in Ashfield, Mass., graduated in medicine in 1827, and practiced his profession in his adopted town for over half a century. He was a member of the Medical Society of the State of New York and of the Medical Society of the County of Chenango.

John J. Zitter, M.D., of Baltimore.—Dr. Zitter, formerly surgeon-general of the Hungarian army, and surgeon-general of the State of Pennsylvania during the late civil war, died in Baltimore on Tuesday of this week. He was prominent as a politician.

Letters to the Editor.

THE EFFECT OF AMYL NITRITE ON THE CIRCULATION IN HIGH ALTITUDES.

To the Editor of the New York Medical Journal:

Sirs: A patient of mine, who had been provided with this drug for her own use in anral vertigo, recently took a trip up the Oroyawand to Chicla, which is twelve thousand two hundred and twenty-five feet above the sea. Learning that people who make this ascent sometimes suffer very much from vertigo and other head symptoms, in consequence of inhaling the highly rarefied air found at such a height, she carried the medicine along, with the intention of resorting to its use if necessary. The trouble caused by ascending to the high altitude of Chicla is known among the Peruvians as soroche.

My correspondent, writing from Callao, Peru, says: "Before leaving the ship I put the two little bottles of amyl which you gave me in my bag, and made the following observations from their use on certain members of the party who were affected: . . . When we were about two thirds of the way up, one of the gentlemen got out to pick some flowers. After walking rather rapidly, he came back with his whole face, especially the lips and nostrils, of a deep purple color; and, in describing his feelings, he said that he was very dizzy, and that his head ached. The inhalation of the amyl relieved him almost immediately, and, although we continued the ascent, his face resumed its natural color; any exercise after this, however, brought the trouble on again, and he was obliged to resort to the medicine frequently until we were well down again on the return journey. On our arrival at Chicla we had breakfast, and, inasmuch as none of us had any nausea, we were told that we were not very badly off; yet we all performed our movements while there very slowly. I felt as if all the blood in my body was trying to get into my head, and water ran from my nose. My own distress was not relieved by the amyl; but still I was able to get about. Just after beginning our descent, one of the ladies was taken with dizziness, and became deathly pale. The amyl relieved her at once, and she was obliged to use it but twice. The pulses of the party, when on the summit, were observed to range from 92 to 128. One gentleman, who became dizzy at the station at Chicla, was relieved by a glass of Italia, which is a kind of brandy made on this coast from the Muscadel grape."

Although these observations may not be regarded with the same interest as if coming from a professional writer, and may not possess the value of repeated experiments in this line of the drug, yet they seem to be suggestive of an important fact, namely, that the heart's action may thus be sustained, under the circumstances related, more promptly than by the use of alcohol or other diffusible stimulants. Thinking that the attention of those who have opportunities to give this drug a trial for the trouble mentioned by my correspondent may be drawn to the subject by this quotation from her letter, I beg to ask a place for this communication in the columns of your journal.

Samuel Sexton.

THE NEW YORK INFANT ASYLUM.

Mr. Vernon, October 24, 1883.

To the Editor of the New York Medical Journal:

Sirs: Will you allow me to make a correction to your editorial comments on the New York Infant Asylum troubles? It was not the East Chester Board of Health, but a coroner's jury who condemned the management of the Infant Asylum, and recommended the district attorney to take the matter in hand. And this action was not taken, as you intimate, because of the death-rate, but because of the evidence of "gross negligence on the part of those having charge of the medical and sanitary departments, and the lack of attention of the president of the society acting under the authority of the Board of Managers." And allow me to add that the absurdity of the affair centers in Mr. Bell's action in procuring an injunction against the East Chester Board of Health, when this board was simply taking measures to guard the village against contagion from the Asylum. The coroner is still at work with another jury, investigating other abuses said to exist at the Asylum. And the quarantine which should be established to protect this village is postponed until the courts decide if the Board of Health can protect the community who elected them for this specific purpose.

E. F. Bresl.

A TEMPTING PROPOSITION FROM A LIFE INSURANCE COMPANY.

To the Editor of the New York Medical Journal:

Sirs: The many malecontents who continually do cry about the insufficient remuneration of professional services will rejoice at the glad tidings that finally light glimmerers at the end of the long and wearying road of medical study. I have before me an alluring multiplicate document from a prominent life insurance company in Boston, intimating that, if I be "thoroughly acquainted with the methods of physical exploration," and can induce two of my professional brethren to vouch for my moral character and scientific attainments, I may aspire to act as an examiner in the district wherein I live, the fee for each examination being fixed at the munificent sum of twenty-five cents. In addition to this positive pecuniary proposal, I am offered the prospective advantage of a possible increase in my private practice through the new acquaintances which I may make among the able-bodied applicants for life assurance, who might, perhaps, learning the amount of my official emoluments, be willing to employ me at the same rate.

Circumstances beyond my control debar me from availing myself of this tempting offer, under which, if business were very brisk, I might earn as much as two dollars a month; but the fraternal sentiment which notoriously actuates all of us in the State of New York impels me to make jubilee the opening which awaits a favored few of those who, having mastered the science and art of medicine, have yet been unable to obtain situations as journeymen mechanics or elevated-railway gate-men. Any such may hear of something to their advantage by
Procedures of Societies.

New York Pathological Society.

A stated meeting was held October 10, 1883, Dr. G. F. Shrady, President, in the chair.

Disease at the Knee-Joint.—Dr. Waardenbeek presented the upper part of the tibia and fibula, the seat of disease, for which he had performed amputation recently. The patient was fifty-two years of age, and about two months before the operation had noticed some swelling of the knee. There was but little pain throughout the course of the disease. During the last three weeks the swelling increased rapidly. The condition joined after amputation seemed to be that of recent haemorrhage occurring after rarefaction of the bony structure of the head of the tibia and fibula. No pus was present. There had been no history of injury, and the patient was able to walk until the time of the operation.

The President referred to the points in diagnosis between these cases and the arthropathies of locomotor ataxia, and stated that he had recently seen two cases of the latter in which the histories dated back two years, and in which pain was almost entirely absent. One of the patients could walk about with perfect ease, except that the joint was not steady.

Strangulated Inguinal Hernia.—Dr. Elliot presented a specimen, giving the following history: On the 18th of July a young man, nineteen years of age, was brought to the hospital, having been seized with the symptoms of strangulated hernia two days before. Attempts at reduction by taxis had been made without success. During the last twenty-four hours there had been stereotonic vomiting; the patient was unconscious, and did not rally after the operation. The strangulated parts were not gangrenous, but were not returned. The points of interest in the case were: The descent of a congenital hernia with strangulation for the first time at the age of eighteen years, the result of the case with almost complete absence of general peritonitis, the comparatively good condition of the parts, and the possibility of recovery had the tumor been reduced.

Dr. Carpenter had once operated in a case of strangulated hernia of five or more days' standing. The condition of the gut so closely resembled gangrene that it was questioned whether it should be returned into the abdominal cavity. This was done, however, but the patient never rallied from the operation. An interesting fact in the case was that the physician who first saw the patient took the case to be one of indirect inguinal hernia, and attempted reduction by way of the inguinal canal. It being really a case of direct inguinal hernia, his efforts had simply resulted in increasing the size of the tumor.

Dr. Peters reported progress from the committee appointed to investigate the subject of Scarlet Fever in Horses. The report gave the result of experiments made by Dr. Sickler upon the inoculation of scarlatinal poison, both in horses and in man. One calf also was inoculated. Blood from a child suffering from scarlatina was introduced into the circulation of the animal. The symptoms produced were more or less uniformly those of redness of the pharyngeal mucous membrane, swelling of the glands of the neck, rise of temperature and pulse rate, running from the nose, eruption, and restlessness. Seven children, who had been exposed to scarlatina, were inoculated either by injection of blood or of the scales of scarlatinal eruption, or by inhalation of the exhalations of a patient suffering from the disease. In all but one case symptoms of the disease followed soon after the inoculation; in that case several days passed before the child showed signs of the disease. The attacks were light. In both did albuminuria develop. The patients recovered. Dr. Peters remarked that, although the veterinary surgeons of New York did not usually recognize that scarlet fever existed among horses, it was described in books on veterinary surgery, and, with diptheria, had been traced back to the earliest periods at which these diseases had been recognized in man, if not earlier. He regarded a certain form of "pink eye," but in which the eye is not likely really to become of a pink color, as scarlet fever; swelling of the glands of the neck, discharge from the nostrils, and albuminuria were much more likely to be present. The danger of men carrying the germs of the disease home from the stables to their children ought to be borne in mind in any case of doubtful origin.

Cerebral Softening.—Dr. Ferguson presented the brain of a patient, a woman sixty-five years of age, who died in the New York Hospital that day. A short time before, she scalded herself to the first and second degrees over the chest, arms, and legs with boiling water. It was stated that she had never been sick before. On admission there was paralysis of both sensation and motion on the left side of the body; the tongue deviated to the left, speech was thick and incoherent, but questions were answered intelligently. The mental condition, however, grew worse; the breathing became stertorous, and the pulse, respiration, and temperature rose. At the autopsy the legs and ankles were found slightly edematous; hypertrophy of the left ventricular walls with moderate dilatation existed; the kidneys were small, the surface granular, the cortex atrophied, numerous hyaline granular, and fatty casts being present in the tubules. There was extensive softening in the right hemisphere of the brain, especially in the parietal region. The ventricles were dilated. In some places, centrally, the cerebral structure was almost completely disorganized. The left hemi-plure was not affected. There was no evidence of embolism, thrombosis, or haeorrhage, unless to a very limited degree. The interest in the case related to the suddenness of the cerebral symptoms, and to the extensive softening without apparent cause. A more careful microscopical examination would be made after hardening of the tissues. It was also of interest to note the extent of the kidney lesions, the numerous casts in the tubules, with absence of signs of renal disease, upon careful examination of the urine.

Dr. Birdsall said that, of the three possible causes of the cerebral lesion—embolism, thrombosis, and haeorrhage—he thought the latter was the most probable, inasmuch as there seemed to be some evidence of slight haemorrhage in the ganglia.

A stated meeting was held October 24, 1883, Dr. G. F. Shrady, President, in the chair.

Sarcoma of the Choroid and Vitreous Body.—Dr. Heitzmann presented a specimen from a man sixty years of age in whom the eye was enucleated for sarcoma. The disease afterward manifesting itself in the liver and elsewhere, the patient had died. The usual signs of the melanoid variety of malignant tumor were present. Dr. Heitzmann considered the case especially interesting, as going to prove the view which he almost alone sustained, that the vitreous body was living and organized, the evidence of which in this case was its distinct separation from the choroid tumor by a fibrous capsule, the disease having, therefore, affected the vitreous independently, and not by cell migration.
Dr. Jacot thought that the question raised was an important one, and that before accepting this case in evidence it would be interesting to know as to the possibility of secondary affection by way of the lymphatics entering the eye anteriorly.

Exstirpation of the Kidney.—Dr. Wylie presented a specimen and gave the history of the case. [Dr. Wylie's account of the case will be embodied in a paper to be published in a future number of the Journal.]

Dr. Howe thought the presence of the tubercles might be considered sufficient cause for the pain which the patient had suffered, without appealing to possible strangulation.

Dr. Jacot thought the impression should not be allowed to go forth that movable or floating kidney was in itself sufficient reason for extirpation of that organ; if, so, a great many women would have to be deprived of their renal organs. He could recall at least thirty cases of floating kidney—mostly in women, some in children, fewer in men—and in not one had there been any indication for nephrectomy. They should be told to wear a bandage, and, if they were slightly discomforted thereby, it was better to bear the discomfort than to have one kidney.

Dr. Wylie doubted whether much would be gained by wearing a bandage; he was inclined to think that a tight bandage in the form of a corset, although worn higher up, was sometimes a cause of the condition. Floating kidney in itself without symptoms certainly did not justify nephrectomy.

Dr. Heineman said that as many as half a dozen cases of floating kidney were seen at Professor Clark's clinic nearly every winter, mostly in women. It was true, as suggested, that the pus in the urine at present in Dr. Wylie's case might come from the ligated ureter, but it was improbable that it came from the other kidney, for usually tuberculosis affected both of these organs at the same time.

Strangulated Hernia.—Dr. Howe presented a specimen, removed from a man, forty-five years of age, who said that he had had a hernia for thirty years, but that it had never before given him any trouble. October 19th, while dressing meat—his occupation being that of a butcher—he felt sudden pain in the groin; the swelling grew red, and the pain continued. He vomited three or four times daily, and had not had a passage since the attack. He entered the hospital October 23d, when he was suffering great pain and was in a condition of partial collapse. The oblique hernial swelling had been injected. Three or four inches of gangrenous intestine were removed, and the ends stitched to the edges of the sac. The patient would doubtless die. The case was one illustrating the sad results of neglect. Evidently no attempts had been made at taxis.

Dr. Wylie stated that he had seen a case in the country in which the physician had refused to operate for strangulated hernia because, as he said, the day was too cold. An artificial anus formed, and the patient was still confined most of the time to the bed, about a year after the accident. He asked Dr. Howe if the opening should be closed.

Dr. Howe replied that it should not; that, if it were not large enough, it should be made larger.

Stenosis of the Pulmonary Orbice of the Heart.—Dr. Van Santvoord presented the heart of a child which died at the age of twenty days at the Randall's Island Foundling Asylum. On admission, it was well developed; the respiration and pulse were rapid; there was a loud murmur over the whole of the chest, most distinct to the left of the sternum at its junction with the third and fourth ribs. The child was not cyanotic, but cyanosis developed, and it apparently died of cardiac failure. At the autopsy the semilunar valves of the pulmonary artery were found much thickened and shortened, causing marked stenosis. It had also been stated that the tricuspid valve was affected. But this was not evident from the specimen in its present condition. There was marked hypertrrophy of the right ventricle, the ductus arteriosus was widely open, the inter-ventricular septum perfect. There was no atelectasis.

Rupture of the Heart.—Dr. Ferguson presented two hearts the seat of rupture. The first specimen was from a man about fifty years of age. He had suffered from an attack of dyspepsia, and about two hours afterward, having gone to the water-closet, was found dead. At the autopsy the body was found well nourished, and there was no edema. The kidneys were markedly atrophied, giving the usual signs of diffuse nephritis. The lungs were congested and edematous. The pericardium was distended with pure blood. The heart was normal in size; the walls were the seat of degeneration; the left ventricle was ruptured near its apex a distance of three quarters of an inch.

The second case was that of a man, forty-four years of age, who in September last sustained an injury on the dorsal aspect of the left hand; the soft parts were torn off and the flexor tendons exposed. The wound was dressed antiseptically, and did well for three weeks, when tetanus developed; the patient suffered greatly from dyspepsia, and died in a convulsion. The pulse had been strong and regular, slightly faster than normal, the temperature 99° to 101°, the respirations 40 to 50. At the autopsy the brain and spinal cord were found intensely congested, the lungs congested and edematous, the pericardium containing one hundred cubic centimetres of blood, the cavities dilated, the ventricular walls thin, the muscular tissue brownish, and the valves competent, with a few small patches of atheroma in the mitral valve. There was an opening in the right ventricle large enough to admit an ordinary probe. The walls around it were about a line in thickness. One was, therefore, a case of rupture of the heart, the seat of myocardiitis, with marked diffuse nephritis, and the other of rupture in the convulsions of tetanus, the heart being normal.

Abscess of the First and Second Dorsal Vertebrae; Death with Cyanosis.—Dr. Chapin had seen a female child, two years and eleven months old, brought to the dispensary on the 5th of September, having a cough and a wheezing sound over the chest. Nothing but some bronchial and tracheal rales were made out. The temperature was normal. The child improved. About three weeks later the mother stated that the patient, while playing, turned blue in the face and suddenly died. The first and second dorsal vertebrae were found to be the seat of a large abscess; there were tubercles in the lungs and trachea; there was also an enlarged cheesy bronchial gland. There had been no dyspneia.

Carcinoma of the Stomach, Liver, Spleen, and Intestine.—The specimens were sent by Dr. Stickler. The patient, a man, was fifty-two years of age; had been well up to fifteen months previously. There was no family history bearing on the case. Symptoms began with abdominal pain, for which anodynes and counter-irritants were applied. The pain extended to the right hypochondrium; there was vomiting, but never of pure blood or chocolate-colored matter; the patient rapidly became emaciated. There was constipation, and the urine was scanty; cancerous cachexia appeared. Later on, an irregular tumor was felt at the pyloric end of the stomach. At the autopsy the cecum was found so constricted that it seemed impossible for faces to have passed; the transverse colon was drawn downward and attached to the ascending colon, and also to the gall-bladder and spleen; the liver was small, firm in consistency, attached to the spleen by fibrous bands; the stomach lay behind the liver, was the seat of cancerous degeneration, and was much smaller than normal.

Dr. Peters made a few remarks on scarlet fever in horses.
NAPHTHOL—its Medicinal Uses and Value—Dr. John V. Shoemaker read the following paper:

Naphthol is one of the remedies of recent introduction, and of the two products of that name the \( \beta \) naphthol is the one which was first used by Professor Kaposi as a substitute for the tar preparations in skin diseases. It was thought by him to be the essential and curative ingredient of tar, while it was free from the objectionable features of the latter. My attention was directed to this remedial agent by Dr. Justus Wolff, a chemist largely interested in the manufacture of coal-tar products, who kindly furnished me a paper on the chemistry of this substance, along with an account of some novel properties which he had observed in it. As this paper, however, is too long for reproduction here in its entirety, and, besides, is largely of chemical interest only, I will here give it briefly in abstract as far as will be necessary to acquaint us with the chemical character of its subject, as follows:

Naphthol is a derivative of naphthalene, a hydrocarbon found in large quantities in coal-tar, belonging to the so-called aromatic group. In the fractional distillation of coal-tar, various hydrocarbons are obtained at different degrees of heat. Thus, at 60° C., benzol distils over; between 60° and 110° C., benzol and toluid mixed; at 111° C., toluid alone; from 111° to 136°, toluid and the different xylens mixed; from 136° C. to 142° C., xylens only; then the cuminene, phenol, and cresols; and at 218° C., naphthalene, which sublimes in colorless, transparent, brilliant, crystalline plates, possessed of a disagreeable, pungent odor, the empirical formula of which is \( \text{C}_11\text{H}_{14} \). Naphthol is produced from this by a substitution of one of the hydrogens in naphthalene by one molecule of hydroxyl = \( \text{OH} \). According to the different positions of the hydrogen substituted in the naphthalene by the hydroxyl, two different naphthols are obtained, of which one is called a naphthol, and the other, the one we shall alone speak of hereafter, is the \( \beta \) naphthol of the formula \( \text{C}_11\text{H}_{13}\text{OH} \). The naphthols demonstrate the advantage of a knowledge of the relative and positive positions of substitution in order to understand the cause and constitution of the different off-springs from simple or compound constitutions. The method of procuring naphthol is like the general process employed in effecting hydroxyl substitutions by first producing monosulphonic substitutions, by means of strong sulphuric acid at certain temperatures, and converting the monosulphonic compound with sodium hydrate, the ordinary dry caustic soda. In the case of naphthalene treated thus with sulphuric acid, the naphthal-monosulphonic acid is produced according to the following formula:

\[
\text{C}_11\text{H}_{13}\text{SO}_3\text{H} = \text{C}_11\text{H}_7\text{SO}_2\text{H} + \text{H}_2\text{O},
\]

which, on being melted with sodium hydrate, yields the sulphonic hydroxyl, or naphthol, as per formula herewith:

\[
\text{C}_11\text{H}_7\text{SO}_2\text{H} + 2(\text{NaOH}) = \text{C}_11\text{H}_7\text{SO}_4\text{Na} + \text{OH} + \text{NaOH}
\]

\[= \text{C}_11\text{H}_6\text{OH} + \text{SO}_4\text{Na} + \text{OH}_2.\]

According to the different temperature employed in the sulphonation of the naphthalene, either \( \alpha \) or \( \beta \) naphthol is derived by the last process. The naphthols thus produced are usually purified by distillation and brought in the market as crystalline masses of a reddish color, and a disagreeable and pungent odor, as shown in the specimen here with submitted. The \( \beta \) naphthol crystallizes in scale like chlorohombicoid lamina from watery solutions, while in a molten state it represents chlorohombicoids prisms. It dissolves in 522 parts of water at 60° F., and in 75 parts of boiling water. It is readily soluble in alcohol, ether, and chloroform. An aqueous solution is colored yellow by chloride of lime, and, by heating this solution, yellow flakes separate. It melts at 122° C. (Schaeffer), but a mixture of both \( \alpha \) and \( \beta \) naphthol melts at a lower temperature than either alone. Compounds with alkaline metals or ammonia and alkaline earths are not stable, and separate easily, either by evaporation or in contact with carbonic acid. The naphthols stand in the same relation to naphthalene as phenol to benzol and cresols to toluol. If one of the six hydrogens in benzol is replaced by hydroxyl, phenol is obtained; in the same way are cresols and naphthols formed. By this analogy of constitution and activity, it is not surprising that they prove allike in their disinfectant character as well, and in order to prove this I undertook a series of experiments. Of course, the medicinal naphthol for that purpose was out of question, and I experimented, therefore, first to obtain a naphthol free from odor. As the crude article contains, as contaminations, sulphur and sulphurous acid, the sublimes thereof will yield, besides the naphthol crystals, also sulphurated hydrogen, thionaphtholes, carbolic and cresylic acid, thio-phenols, and the like, to which ordinary naphthol owes its pungent and disagreeable odor. I avoided this all by passing a rapid current of steam through its aqueous solution, expelling thus all volatile by-products, and obtained naphthol in its greatest state of purity, in beautiful silver crystalline scales, as here submitted. This naphthol may again be sublime and obtained, then, in elegant white crystals, as here shown; but by the heat employed, more or less decomposition again takes place and renders the product somewhat odorous and pungent.

In order to test the disinfectant and antiseptic properties of my inodorous naphthol, I added one part thereof, in powder form, to 480 parts of urine, which, at the expiration of six months, at a varying summer temperature, manifests no odor or signs of decomposition, while another of the same urine, without addition of naphthol, had a strong putrid odor after standing for three days only. To this latter I added, after standing thus for eight days, some of my inodorous powdered naphthol in the above-mentioned proportion, and in twenty-eight hours it had lost its putrid odor, and has kept thus up to the present writing, when no putrefaction or signs of it can be detected in either specimen. The same experience I have had with meat immersed in a solution of naphthol, 520 parts of water, as well as in other experiments similarly conducted. Experiments with solutions of the compounds of naphthols with alkalies or alkaline earths prove that these act very much less antiseptically than the solutions of pure naphthol soaps, containing four to ten per cent. of free naphthol, and found excellent and serviceable in removing odors of putrefaction or decomposition from hands or clothes. They are also very efficacious in destroying clothes or body-lice, as naphthol is a very active parasiticide. If naphthol is vaporized by means of heat, the air in rooms contaminated, in consequence of disease or otherwise, will be found to be rapidly deodorized and rendered fresh and sweet without other odors, making it thus of the greatest value for sick-rooms, hospital wards, dissecting-rooms, etc. As carbolic acid has many disadvantages, and is not the deodorant or antiseptic par excellence, the inodorous naphthol can certainly take its place in every respect.

As naphthol has been described variously as poisonous and injurious to the animal economy, which by its composition and analogy was not apparent, I felt it my duty to experiment with it in regard to such, and commenced at once, without hesitation, by taking it internally; one part dissolved in 3,000 parts of water produced at first heart-burn, a slight sensation in the right lumbar region, and some dizziness. Of that solution an equivalent amount was taken to represent a half-grain. These symptoms disappeared after continuing its use for some days, and, while the urine showed upon analysis traces of naphthol and naphthol compounds, no albumin or blood could be detected therein. The doses then were gradually increased to four grains per day for six days, and still no untoward symptoms were discovered, while the warmth in the stomach, directly after taking, was followed by increased appetite. Dr. Schofield, of Albany, reports to me that, upon my communication, he has used it largely, at first experimentally in the Albany Hospital, where it has now become a staple article, and is used almost entirely to the exclusion of other disinfectants and antiseptics. They use it there for all kinds of disinfection in wards, sick-rooms, for wounds, etc., and have abandoned carbolic acid in all but a few cases, and always with the greatest satisfaction and success.

Thus far the paper of Dr. Wolff. His experience, as well as that of Kaposi and others, led me, some eight or nine months ago, to employ it both in private and hospital practice, and the success attained with it soon led me to further experiments. I found it to fully sustain the claim that Kaposi had made for it
in scabies, psoriasis, and chromophytosis, as well as in some of
the chronic forms of eczema, in which it not only allayed the
itching attendant therewith, but lessened the inflammation as well.
In wounds and indolent ulcers I have found it a most useful de-
tergent and deodorant, removing the fester and establishing
healthy action of the parts. Aqueous solutions, containing half
a grain to the ounce, I have used to great advantage as vaginal
injections, especially in lacerorrhoea and uterine carcinoma, as
well as in gonorrhoeal affections, both in males and in females.
In diphtheritic throat affections it made a most useful gargle, as
well as to remove the fester of entarhial and other affections of
the buccal cavity. Its greatest value, however, arose from its
disinfectant action on the evacuations of fever patients and the
rooms containing them, while by its absence of odor it did not
tend to produce inconvenience either to patient or attendants.
Combined with powdered tallow or starch, or both, and dusted
into the shoes or stockings of those affected with feet exhaus-
tations of the feet, it acts most satisfactorily, and its effects are
equally as good in the same affection involving the hands and
the axillary and inguinal regions. Combined with other oint-
ments in the proportion of from one to ten grains to the ounce, it
not alone preserves the unguent from decomposition, but exer-
cises also an antiseptic action on the parts and the exudation
therefrom. A slight admixture to an experimental sample of
lard has preserved the same in excellent condition throughout
the hot summer months. In chronic psoriasis, particularly when
there is great infiltration, a five-to fifteen-per-cent. ointment has
frequently been attended with good results. It has also been
very effective in squamous and fissured eczema, used in combi-
nation with lard or gelatin.

To test for myself its antiseptic properties in comparison with
those of carbolic acid, I mixed the whites of two eggs with an
equal weight of water and took one half of this mixture in one
phial, adding one grain of crystallized carbolic acid, while to the
other half, in another phial, I added one grain of Dr. Wolff's odor-
less naphthol. After the expiration of five days the carbolized
albumin assumed a putrid odor, whereas the naphtholized part,
though discolored by the naphthol, remains to this day—twenty
days after the experiment—without odor. A quantity (about
half a pound) of meat, already commencing to putrefy, was also
at the same date immersed in a saturated aqueous solution of
naphthol, with the effect of arresting the putrefaction and pre-
serving it for some time.

After using naphthol so long and successfully without any un-
toward occurrences, I read, to my astonishment and alarm, that
Dr. A. Neisser, in the "Centralblatt für die medizinischen Wiss-
schaften," 1881, No. 30, reported most extraordinary toxic
effects obtained with naphthol, and that also Kaposi reported
having seen haematuria, ischaemia, vomiting, unconsciousness, and
ecchymotic attacks in a boy after the external application of naph-
thol; also that Squire reports, in the "British Medical Journal,"
January 14, 1882, its producing blisters and irritating the skin.
Dr. Piffard regards it as a dangerous remedy, and Professor Kapon,
while he reports good results with it ("British Medical
Journal," p. 759) in scabies, prurigo, and eczema, advises in
prolonged cases simple ointment to be substituted every fourth
week, to avoid any possible risk of absorption. Dr. Neisser
stated that one gramme of a saturated solution (which in water
would contain about one thirtieth of a grain of naphthol) in-
jected hypodermically in a dog produced hemoglobinuria, and
shortly afterward death. To verify these accounts and satisfy
myself of the toxic effect of pure naphthol, if any it possessed,
I administered to one rabbit, repeatedly in twenty-four hours,
three-four minims of a saturated aqueous solution, hypodermic-
ally, without any result, either to inconvenience the animal,
increase his temperature, diminish his appetite, or cause a lethal
effect. This method of treatment was pursued for five days,
not fewer than four to five injections being made each day, and
the result was still the same. Determined to obtain toxic effects
with it, and, if possible, to demonstrate its toxic action by a
post-mortem examination, another rabbit was fed, at first every
two hours, with one-grain pills of naphthol, and subsequently
with two- and four-grain pills, at the same intervals, but, beyond
increasing the appetite of the animal, no special effects were
apparent. In consideration of this, one of my assistants, Dr.
Charles S. Means, and my student, Mr. F. C. Waterman, volun-
teered to take naphthol themselves internally, to test, if possible,
its action upon the human organism. They commenced with
one-quarter-grain doses every two hours, their pulse, tempera-
ture, and urine being subjected to the closest inspection both
before and after. The second day they took a half-grain every
two hours; the third, one grain every three hours; the same on
the fourth, while on the fifth and sixth they took two grains
every three hours, and on the seventh, five grains twice daily.
The pulse and temperature did not appear to be affected by this,
nor was at any time albumin or blood apparent in the urine.

Though they experienced great warmth in the epigastie region
after each dose, that passed away in a short time, but left them
with slight vertigo, buzzing in the ears, with all evidence of cere-
bral hyperemia. The urine evacuations were softened and of
muddy consistence, changed to a clay color, and in one of the
cases increased to diarrhoea.

Arriving at a résumé of my experiments, I must certainly
claim the odorless naphthol which I had received from Dr.
Wolff as not a toxic agent; and, while I have found it a most
useful remedial substance, and a disinfectant and antiseptic of
the greatest value, it does not, in my experience, confirm the
dangerous influence exercised on the human organism as re-
ported by the gentlemen above quoted, a fact for which I can
only account by the greater purity of the material used by me
—purified from the deleterious contaminations above enumer-
ated by the process already described, which is not employed
abroad, where yet naphthol is sold and used as reddish crystal-
line masses, with strong, pungent, and disagreeable odor. That
it is far superior to carbolic acid and other disinfectants and an-
tiseptics I have no doubt, and I am informed that in price it is
not alone cheaper than the former, but, by its greater efficacy
and the smaller amount necessary, it is certainly more advan-
tageous, aside from its greatest recommendation of being almost
absolutely odorless. It must be borne in mind that all my re-
marks apply to odorless naphthol—only such as I have exhibited
—and that I consider that alone as safe for medicinal use.

Note on Hydargyrum Formamidatum.—A paper with this
title was read by Dr. James C. Wilson: Some accounts of this
preparation have appeared in recent journals. Toward the close
of last year, Professor Liebreich proposed, in a meeting of the
Berlin Medical Society, a new drug for the treatment of syphilis
by the hypodermic method. Chemically this drug belongs to
the amide group. Liebreich was led to use it from the fact that
the ordinary amides of the body, of which urea is the principal
one, are eliminated in an unchanged state. When, however,
the amide is in combination with a metal, decomposition occurs,
and the metal is reduced and deposited. Liebreich found, by act-
ual experiment, that this statement is true of mercury. It is
supposed that the formamidated mercury, after hypodermic
injection, undergoes decomposition, and that the metal mercury
is set free in the tissues. The preparation is soluble in water,
of neutral reaction, does not congeal albumin, is not precipitated
by caustic soda, and the presence of mercury can be demon-
strated by potassium sulphide. It produces its effects very
surely and rapidly. Liebreich regards it as the best remedy
known for the hypodermic treatment of syphilis by mercury,
as it is but little liable to excite local troubles or salivation. Later ("Medical Times and Gazette," July 7, 1888), we find that Professor Zeissl, in Vienna, after trial of this remedy in fifteen cases of syphilis, was well satisfied with the results. In three of these cases salivation was produced. Some pain followed its injection, which was not, however, so severe as that following the hypodermic use of mercuric bichloride. Twenty injections was the maximum number required to disperse the manifestations, even in severe cases.

Dr. Schnecht, of Berlin ("New Remedies," Sept., 1883), writes as follows: "Formamide is a colorless liquid, boiling at about 195° C, which can be distilled without decomposition only in vacuo. It is prepared by acting upon formate of ethyl by ammonia. When pure, it is neutral, but easily becomes acid. If a concentrated solution of formamide be boiled with precipitated mercuric oxide, decomposition ensues, and metallic mercury is separated. On the other hand, if a dilute solution of formamide be warmed on the water-bath with precipitated mercuric oxide, a clear, colorless solution results, in which soda (hydrate of sodium) produces no precipitate. Sulphide of ammonium, however, precipitates the mercury as sulphide, both from the formamide of mercury and from mercuric chloride. Solution of albumin precipitated by the latter salt, but not by the formamide. Formamide of mercury is prepared in the following manner: 10 to 18 grms. of freshly precipitated, completely washed, and still moist mercuric oxide are gently warmed with a little water in a porcelain capsule, with gradual addition of 10 grms. of formamide. As soon as solution has taken place, the resulting colorless liquid is filtered into a litre-flask, and the latter filled to the litre-mark with distilled water. Each cubic centimetre contains 0.91 grm. of mercury, which is the quantity representing one hypodermic dose. Formamide of mercury keeps well in brown-colored bottles, and should also be dispensed in these."

In a note from Vienna ("Medical News," October 13, 1883), it is stated that Professor Neumann is now trying hydrocyanic acid formamidatum on a large scale as an anti-syphilitic. It is used hypodermically in doses of 1 c. c. It acts with far greater efficacy upon the recent efflorescences than upon the later manifestations. Pain of great severity and active local inflammatory troubles have resulted in Neumann's cases. The preparation which I exhibit, made by Merck, of Darmstadt, is a one-per-cent., aqueous solution, and the dose of it from half to one ordinary hypodermic syringe full. It has not been possible to obtain this drug in this city until the present time. I would be glad to place the specimen which is exhibited in the hands of any member of the society who may desire to make a trial of it chemically.

The Treatment of Psoriasis.—Dr. Arthur Van Harlingen read the following paper: Psoriasis is one of the common skin diseases met with in this country. The statistics of the American Dermatological Association show that it occurs in the proportion of about six per cent, in all diseases of the skin encountered. Daily experience would seem to indicate a still more frequent occurrence, because the affection is a disfiguring and annoying one, and therefore patients are more inclined to seek relief, and also because it is a stubborn disease and greatly prone to relapse. The history of a single case will often extend over many years, and bring it under the observation of a number of different physicians. It is because of the comparative frequency with which psoriasis is met and its stubbornness to treatment that I have selected it as the subject of my remarks this evening. Having had a good deal of experience in the treatment of the commoner forms of the disease, it is my intention to confine myself chiefly to the consideration of such remedies as have come under my own observation and use, only touching incidentally on others.

The object of treatment in psoriasis is the removal of the eruption as it exists upon the skin. We can not hope with any degree of certainty in any given case to prevent a recurrence of the disease, or, if you please, a relapse. For the drug has not yet been discovered which will surely take away all tendency to the recurrence of psoriasis; and whoever promises a cure, in the wider sense of the word, to his patient, will, in a very great number of cases, find that he has been too sanguine. Fortunately, however, a certain number of patients do seem to recover. I do not know what has been the experience of others in this respect, but I have patients who have been under observation three, five, even eight and ten years without relapse. Such cases are, unfortunately, few.

Pre-eminent among the internal remedies which are useful in the treatment of psoriasis is arsenic, which may be justly called a specific in this disease. I think I am not asserting too much when I say that eight out of ten cases of psoriasis of average character and severity will do better under the use of arsenic than with any other remedy. I prefer Fowler's solution, given in the average dose of four minims thrice daily. I think this solution is often prescribed in too large doses, and I am sure the dose of five to ten minims, as given in the books, is too large for ordinary use. Most patients bear a four-minim dose very well, but there are idiosyncrasies. I have sometimes been obliged to limit the dose at the beginning to one minima in cases where subsequently such toleration has been established that twelve minims have been taken with impunity. However, four minims is a good dose to begin with, and, if the effect does not begin to show itself within ten days or two weeks, the amount may be gradually increased. Fowler's solution should never be given to the patient in a phial with directions to drop out the requisite number of drops. The patient is apt to make a mistake, phials of different sizes may pour out more or less in each drop, and there is always danger in leaving a half-empty phial of poison about the house. The solution is better given mixed with water, or with wine of iron or other convenient vehicle. The effect produced by arsenic upon the eruption of psoriasis is, first, in diminishing the quantity of epidermic scales thrown off, and then in preventing the appearance of new lesions. The patches gradually lose their scaliness, begin to heal in the middle, and disappear little by little. It must be remembered, however, that arsenic is a slowly acting remedy, and its use should be continued through many months to get the best security against relapse. The other liquid preparations of arsenic used in psoriasis are Pearson's solution of the arsenate of sodium, and Donovan's solution of the iodide of mercury and arsenic. I have used the former in a few cases without noticing any perceptible difference as regards efficacy between it and Fowler's solution. The solution of mercury and arsenic (Donovan's) I have employed in certain stubborn cases with good effect where Fowler's solution has seemed to fail. The existence of syphilis as the cause of the eruption in these cases having been excluded, I am at a loss to account for the apparently greater efficacy of the mixed treatment. The dose given was as much as ten drops, and, although this solution is weaker in arsenic than Fowler's, yet I am inclined to the opinion that the conjoint administration of the two drugs, mercury and arsenic, was the cause of the good result rather than the increased dose. I should be inclined to use Donovan's solution in cases where Fowler's solution had failed. The mixture of arsenic acid, black pepper, and sugar of milk, known as Asiatic powder, and recently placed in the Pharmacopoeia with the pepper left out, among the triturations, is of no particular value above the other preparations, and is not so convenient of administration. Hypodermic injections of solutions of arsenic have been employed in the treatment of psoriasis, but I have had no experience in their use.
Next in value to arsenic in the treatment of psoriasis is iron, I commonly employ the tincture of iron in cases where arsenic does not seem indicated. There is one type of psoriasis which includes robust, rosy, well-nourished individuals, “the very picture of health.” Such people have never been sick a day in their lives, or perhaps may have had slight attacks of articular rheumatism. Such patients do well under arsenic. But there is another type in which the individual is thin, poorly nourished, and perhaps somewhat anemic. These are the cases which do well under iron, which is best administered in the form of the tincture of the chloride. With these two remedies, arsenic and iron, I usually succeed in curing ordinary cases of psoriasis, adding in rare cases cod-liver oil to the use of the tincture of iron when necessary. Of course, local applications are employed at the same time. Of these I shall speak presently.

In addition to the internal remedies mentioned, quite a host of others have been employed from time to time. Such are tar, carbolic acid, copaiba, phosphorus, tincture of cancaries, tincture of unze, carbonate of ammonium, acetate of potassium and other diuretics; the alkalies, as liquor potasse and the alkaline mineral waters. Of these, I have found alkalies and diuretics useful in cases when a markedly inflammatory condition of the skin has existed. The other remedies I have not employed, nor do I think the reports of their usefulness based on a sufficient number of facts, except in the case of tar possibly, to make it worth while to try them.

Equally important with the internal treatment of psoriasis is the external management of the disease. It is, of course, desirable to remove the eruption as soon as possible, wherever it may be situated; but when it is found upon the face, there is every reason to endeavor its cure by all means, and in the shortest time. External and internal treatment should therefore be combined when practicable. The first thing to do is to remove the scales. This may be done by means of local or general baths, wet dressings, etc., or by inunctions with fats and oils, by the use of soap, or by the action of impermeable dressings of indiarubber or oil-silk. When only a few lesions are to be acted upon, a solution of salicylic acid in alcohol, one part to sixteen, well rubbed in with a sponge, will remove the scales very nicely. The scales having been removed, the next thing is to apply such substances to the diseased patches as may most quickly modify the abnormal condition of the skin, and bring it back again to a healthy condition.

An innumerable number of applications have been recommended for this purpose, the most of which I shall pass over with only a mention. Such have been soaps and alkalies, citric and hydrochloric acids, sulphur, iodine, and mercury, alone and in combination, together with the various forms and preparations of tar, creasote, and carbolic acid. All of these remedies have their uses, and most of them, especially the tarry preparations, I have employed time and again in years gone by, and with moderate satisfaction. The introduction, however, of chrysarobin or chrysophanic acid, some six or seven years ago, put quite a new face on the local treatment of psoriasis; and since then, with the aid of this and other later discoveries, we are able to work a much more rapid change in the appearance and condition of the skin in this disease. As chrysarobin is perfectly well known to all here present, both as to its advantages and defects, I shall say but little about it in the ordinary form of its application, namely, as an ointment. When it first came out I tried it quite extensively, but its disadvantages seemed so great that I had already begun to restrict its use greatly in my practice, when a new agent appeared, which, for every-day use, has in my hands, until very recently, almost entirely superseded all other local applications. I refer to pyrogallic acid.

I do not think pyrogallic acid is by any means so well known as an application for the relief of psoriasis as is chrysarobin. If I may judge by the infrequency with which its virtues are mentioned in the journals (although I believe all recent text-books speak of it), it is not in general use. But it is, in my opinion, one of the very best remedies we have for the cure of cases of psoriasis of average severity. Employed in the form of ointment, of the strength of one part to one drachm of the pyrogallic acid to one ounce of simple ointment, the effect produced by it is almost as rapid and decided as that brought about by chrysarobin, without the accompanying discoloration. A slight blackish staining is all that is produced, and the ointment can even be employed in the scalp without markedly discoloring the hair, if applied carefully. It is desirable, however, not to apply soap or alkalies at the same time, because this causes a more permanent and deeper stain. Pyrogallic acid can not be used in extensively generalized psoriasis, when large surfaces are affected by the disease, without a certain amount of danger from absorption, as indicated by stranguary and olive-green or tar-colored urinary secretions. With care, however, and the occasional suspension of the remedy for short periods, I believe this remedy could be employed, even in universal psoriasis, with good effect.

One more external application in psoriasis remains to be spoken of—namely, naphthal. This drug, a derivative of coal-tar, was introduced into use several years ago by Kaposi, of Vienna, as a sort of substitute for carbolic acid. He recommends it very highly in psoriasis, in the form of ointment, about eighty grains to the ounce, and I have used it in this and other strengths, and also in solutions in alcohol and oil, with fairly good effect. Naphthal is not so active in its effect as chrysa-
robine or pyrogallic acid, but it is much more agreeable, and is, I think, peculiarly well adapted for employment upon such parts as are exposed to the view, as the face and hands. Like pyro-
agallic acid, it must be used with caution over large surfaces, as absorption with toxic effects may be produced.

It remains to mention briefly two or three methods of application of these remedies which have recently been brought forward. The first of these is the treatment by medicated gelatin which was introduced by Professor Pick, the well-known dermatologist of Prague. My attention was first drawn to this by a pamphlet which Professor Pick kindly sent me, in which he gave an account of his earlier experiments with medicated gelatins, but I have not as yet had an opportunity of testing this method of medication as I should desire. I may say, however, that the method does not seem to me calculated to prove convenient and popular in private practice. I had for some time been making some experiments in my service at the Polyclinique in the preparation of gelatins impregnated with chrysarobin and pyrogallic acid, but without much satisfaction, when Dr. Charles L. Mitchell, the well-known pharmacist of this city, sent me some excellent preparations of his own, which seem to be perfectly adapted to the purpose for which they are intended.

A bit of one of these gelatin sticks is cut off and placed in a water-bath, where it soon melts into a clear homogeneous fluid, which may then be applied to the lesions of the skin by means of a paint-brush. The advantages claimed are cleanliness and transparency. The coating of gelatin does not rub off on the clothes, and is therefore not so dirty as an unctuous application. A fresh coating can be painted on every day or two as the old

* In a communication read before the American Dermatological Association last month, and published in the “American Journal of the Medical Sciences" for October, I have given the results of my experience in the use of naphthal in various diseases of the skin, psoriasis among the number. I may refer to that paper for further details as to the action of the drug in this disease.
layer wears off. The chief disadvantage of this method of treatment is that it requires apparatus which is not convenient to carry about, nor can the patient be trusted to employ it at his discretion. My own experience is that in psoriasis, at least, the gelatin applications are not active enough. I have not, however, used them with sufficient frequency to pronounce a positive opinion.

Recently a solution of chrysarobin in collodion has been recommended in the treatment of psoriasis by Dr. George H. Fox, of New York, and several dermatologists have confirmed his statements with regard to its efficacy. I have employed this preparation in one or two instances, but it has seemed to me so much less active than the chrysarobin ointment that I have not been encouraged to continue its use. It has one great advantage over the gelatin applications, however, and that is, that it can be applied extramurally and without the paraphernalia which must accompany the use of the gelatin.

A few weeks since a pamphlet by Professor Auspitz, of Vienna, reached me, in which that distinguished dermatologist recommended liquor gutta percha as a vehicle for the application of chrysarobin. I at once obtained a ten-per-cent. solution, or rather emulsion, of chrysarobin in liquor gutta percha, and happening to have a case of psoriasis of the face and scalp under treatment, I gave some to the patient to apply once daily. The effect was so happy as to encourage me very much to hope that we have in this preparation the most convenient method of applying chrysarobin yet devised: and as chrysarobin is, after all, the most efficient local agent in the treatment of psoriasis as yet brought forward, I have no hesitation in urging the trial of this preparation on any one who may have a case of psoriasis under treatment. It is to be noted, however, that the same watch must be kept upon the skin, for fear of exciting dermatitis, as when the ointment is used. Only when the liquor gutta percha dries, which it does very quickly, there is little or no danger of rubbing the chrysarobin over the good skin, nor is there much danger, if any, of staining the clothing.

Miscellany.

Therapeutical Notes.—The Therapeutic Use of Douches of Compressed Air.—M. Maurice Dupont has obtained good results ("Bulletin general de therapeutique," September 30, 1883) from the therapeutic use of douches of compressed air. M. Dupont believes that aerotherapy need not be confined to the treatment of diseases of the lungs and respiratory passages, but that it may be applied effectively to various affections characterized by impaired nutrition. By the influence, mechanical and chemical, of an atmosphere more dense and richer in oxygen, it is possible to increase, decrease, or modify the processes of nutrition when they are perturbed. He has extended the methods of application to embrace baths and douches, in order to make use of the mechanical force of compressed air as an agent of "flagellation," and the cold produced by its liberation as a refrigerant. The douche of compressed air, applied like the douche of water, is of benefit to patients of delicate constitution, who would be proper subjects for hydropathic treatment, if they reacted better after the use of cold water. M. Dupont employs compressed-air douches under a pressure of three atmospheres. The air is conducted through a pipe of canvas and canvashose, provided with a nozzle eight to ten millimetres in diameter at its orifice. The jet of compressed air is directed against the patient, who lies stripped upon a couch.

The results are: 1. "Flagellation;" deep depression of the integument where the air strikes it; displacement and gliding of the superficial upon the deeper tissues; veritable massage, which sends back the blood in the vessels from the periphery to the center.

2. Cooling of the skin and rapid reaction due to the energetic flagellation, which brings a glow to the surface. The patient, as soon as drenched, dresses himself, no friction being required to warm him up. Not having been wet, he is not exposed to the evaporation which follows the use of water, and which, by the subsequent chilling it causes, is liable to neutralize the good gained by the reaction. If, however, the patient be vigorous enough to justify it, the lowering of temperature by the douche may be made still greater by mixing a little water with the air. The water is thrown in a finely divided condition, and the current of air produces a very rapid evaporation, and therefore a marked reduction of temperature. Indeed, this may be carried low enough to produce local hemi-anesthesia. The douche not only leaves a feeling of warmth all over the surface, but it produces a marked sense of freshness and vigor. However great the reduction of temperature may have been, a reaction will almost invariably follow, and follow almost immediately. The anesthetic properties of the douche may be increased by mixing carbonic-acid gas with the air.

M. Dupont believes that the douche of compressed air is indicated in: 1. Pulmonary tuberculosis, chlorosis, anemia, obesity, rachitis, etc., to increase the activity of the nutritive processes. 2. Oedema, hydrarthrosis, ankylosis, etc., to improve the circulation and favor the absorption of effused fluids. 3. Various cases of paralysis, as an adjuvant to electricity. 4. Hyperesthesia, hysteria, contractures, etc.

The Presence of Sulphate of Quinine in Sulphate of Cinchona.—In discussing these topics before the Paris Therapeutical Society, M. Catillon raised the question whether the febrifuge properties attributed to sulphate of cinchonine were not due to the sulphate of quinine which the former salt, as prepared for commerce, contained in considerable quantity. M. Dujardin-Beaumetz expressed the belief that the sulphate of cinchonine acted like the sulphate of quinine, but that its action was not so regular or so energetic. It was a sort of "second-chop" sulphate of quinine [de second marque]. Furthermore, the researches of M. Moutard-Martin had shown definitely that it possessed febrifuge properties. M. Tanret thought that the proportion of alkaloids in the different varieties of cinchona bark was a matter of more importance to manufacturers of quinine than to pharmacists. In point of fact, but a small part of the alkaloids of the bark—a third part only—was soluble, and appeared in the various pharmaceutical preparations of cinchona.

The rest was insoluble, and, together with the red coloring matter, remained in the residuum. M. E. Petit could not share this opinion. In the first place, specimens of cinchona bark were to be found in commerce which did not contain a trace of quinine. There was, then, a great advantage in analyzing the bark before using it in pharmacy. Moreover, three quarters of the alkaloids of cinchona obtained from Java could be extracted by water alone, and the entire strength of the bark could be exhausted with fifty-six-per-cent. alcohol. Furthermore, according to the new code, it was allowable to extract the alkaloids first by the action of water, and to complete the extraction by means of an acid liquor. M. Tanret was confident that, even with an acid liquor, all the alkaloids could not be extracted, at least without the use of a prejudicial quantity of acid. He promised to communicate the results of his experience on that point.

Disease Germs; their Vitality; Means of Rendering them Inactive.—M. Paul Bert, President of the Paris Society of Biology, in discussing the question of disease germs recently before that society, stated that he had received numerous letters from persons engaged in handing mercury who believed that their occupation afforded them immunity from contracting cholera. Workers in copper are said to enjoy a like immunity from the disease. These supposed facts led M. Bert to seriously question whether there did not exist for each sort of disease germ a destructive agent in the presence of which the germ was unable to develop. M. Davaine, with the view of answering this same question, instituted a series of experiments upon the bacteria of anthrax. M. Bert, with M. Capitan, undertook a similar series of experiments upon the virus of glanders. This virus, "sown" in solutions of sulphate of copper, bichloride of mercury, chloride of gold, or in oxygenated [ozonized] water, was not fruitful; on the contrary, its development was rapid in solutions of permanganate and of carbonate of potassium.
A first question relative to the vitality of disease germ is, then, one of the medium in which they find lodgment. But the question is also pertinent if, even in a hostile medium, the germ can not multiply if the quantity of the virus is considerable, or if the medium which receives it is not up to the standard strength, as, for example, an organism that has been overworked and exhausted. M. Bouley observed that it manifested the true appearance that they were more liable than others to contract glanders or other contagious diseases. The experiments of M. Chauveau on sheep proved that large quantities of virus would avail when small quantities were inserted. He produced anthrax in animals by the introduction of virus in considerable quantities when smaller amounts introduced into the same animals had failed to generate the disease.

The Treatment of Badlorn.—M. Vidal ("Gazette hebdomadaire de médecine et de chirurgie") details some points from his personal experience in the treatment of baldness. He had used blisters, but had often found ordinary blisters painful, difficult of application, and liable to cause cantharidism, unless special precautions were taken to prevent this accident. Desirous of finding a less objectionable means of producing blisters, he experimented with all the preparations of Duplane guillotum, but without success. Subsequently he used a preparation known in Java under the name of "Andolandel," which had been recommended by Van Leent, of Holland. This vesicant tincture is obtained from Lyto rubidz. It gave very good results, and was not painful. Having exhausted his supply of andolandel, he tried a vesicant tincture prepared by his former pupil, M. Bidel. Two or three coats of this were applied with a brush, the surface having been previously well cleaned. Complete evacuation took place, without any considerable pain, in about two hours and a half. This tincture is prepared from the seed by macerating for twenty-four hours, first in cold alcoholic and afterward in a water both with four parts, by weight, of ninety per cent. alcohol. Thus made, it contains nearly 12 per cent. of cantharidin.

M. Vidal used the same tincture to blister the chest in affections of the lung and pleura. Cantharidism never occurred. The desired amount of vesicant action may be produced by the use of one or more coatings of the tincture. M. Féris is of the opinion that this treatment may be satisfactorily carried on by means of a vesicant principle, used in Cochín China, which is obtained from an insect known under the name of hopo-op. He had never known that preparation to cause any accidental analogous to cantharidism.

The Treatment of Pulmonary Phthisis and other Wasting Diseases.—Dr. Joseph A. Síttes, of Belmont, Nevada ("Cincinnati Lancet and Clinic," October 29, 1885), advocates the use of oleum lini as a substitute for oleum morrhuae in pulmonary phthisis and all other wasting diseases. He has obtained better results with it than he could get with coelir oil, or with any of its emulsions. No attempt should be made to push the oil until diarrhoea is produced. The old rule requiring this should not be followed. Comparatively small doses are quite sufficient. Oleum lini may be made palatable by combining it with honey and with any of the maltine preparations, as in the following formula: 30.0, linum, raw, 50; mel. rose, 5; maltine, q.s., ad jv. M. Sig. A tablespoonful three times a day. If desired, branny, whisky, or other alcoholic stimulants may be added. Thus prepared, either with or without any preparation of alcohol, linseed-oil will be taken by patients uncomplainingly, and oftentimes with a marked improvement in their nutrition, and with all the benefits which such improved nutrition produces. Children convalescing from fever or whooping-cough, or who are the victims of malnutrition from any cause, are benefited by oleum lini. They may be given a teaspoonful or more of the above-mentioned mixture, according to age. The old idea that linseed-oil impairs digestion Dr. Síttes believes to be erroneous, if it be given in moderate doses and in a palatable form.

[As many of our readers are doubtless aware, linseed-oil has been used on a good deal in New York of late years, at the suggestion of Dr. Samuel Sherwell, of Brooklyn. It has been found that bread made with a certain proportion of linseed-meal mixed with the flour is not unpalatable.]

The Administration of Powdered Meat.—M. Caillou proposes ("Gazette hebdomadaire de médecine et de chirurgie") a new formula by means of which powdered meat may be given without exciting the aversion of patients. It is as follows: To two spoonsfuls of the powder add a little sugar and two spoonsfuls of Madeira wine. Mix thoroughly, and, after the sugar has been completely dissolved, add four spoonsfuls of water. The thorough mixture of the meat-powder with the wine before adding the water is essential to the complete suppression of the disagreeable odor of the powder.

Quinidine and its Allier.—Researches into the action of the secondary alkaloids of quinidine resulted in the valuable addition of codeine to the Pharmacopoeia. The investigations of M. Laborde give reason to hope that benefit may arise to medicine from the further study of the secondary alkaloids other than cinchona quinidine, which are found in cinchona. That observer has lately given much attention to the study of the physiological action of quinidine. This principle he finds to agree with cinchonine and cinchonidine in producing convulsive movements of the body, while quinine appears to be incapable of doing so. A guineapig, beneath whose skin some sulphate of quinine was injected, quickly passed into a stupid semi-conscious state, and was seized with opisthotonic convulsions. Tonic and clonic muscular contractions succeeded another till death by asphyxia ensued three quarters of an hour after the injection. Cinchonine and cinchonidine possess the convulsive property in a more marked degree than quinidine. This drug, therefore, holds a middle position between the alkaloids just mentioned on the one hand, and quinine on the other; but its affinities are stronger on the side of the former group. An impure specimen of sulphate of quinine, experimented with in like manner, gave the convulsive reaction, thus proving the presence of the other alkaloids, and illustrating a remark of M. Laborde, that one advantage gained by his experiments is the establishment of a physiological test of the purity of these substances.—British Med. Jour.

Hairdressing.—We are indebted to Dr. S. C. Gordon, of Portland, Me., for a copy of an interesting paper read by him at the last meeting of the Maine Medical Association, entitled "Results of Treatment of Injuries occurring at Parturition," from which we extract the following:

"In perinorrhaphy there is one caution to be observed, the lack of which has caused many a patient to regret having had it performed. I allude to the use of too many sutures. In my own practice, I have found several cases where the vaginal passage was too small, and coitus necessarily painful. This is no unimportant matter, but one that we are bound to regard. If the last suture is carried up through the undenuded mucous membrane, thereby drawing the posterior wall down and covering the wound, and by so much shortening the vagina, we obtain a perineal body sufficiently strong and thick, without closing the vulva so high as to interfere with the proper sexual relation. After no one of these operations do I allow the etieter to be used, unless the patient is unable to evacuate the bladder. Its use is almost sure to produce more or less cystitis, which continues, in many instances, for months. Neither do I allow the bowels to become constipated, much less take measures to check them. They should be kept soluble, so that no fecal impaction shall occur."

A Seventh Sense.—Sir William Thomson, the eminent professor of mathematics at the University of Glasgow, in his inaugural address, delivered last week, as President of the Midland Institute, at Birmingham, broached the idea of the existence of a magnetic sense. This sense he called the seventh sense, to distinguish it from our other six senses—namely, those of sight, hearing, taste, smell, heat, and force. He said that, in speaking of a possible magnetic sense, he in no way supported that wretched groveling superstition of animal magnetism, spiritualism, mesmerism, or clairvoyance, of which they had heard so much. There was no seventh sense of a mystic kind. Clairvoyance, and so on, was the result of bad observation chiefly, somewhat mixed up with the effects of wilful imposture, acting on an innocent and trusting mind. If there were not a distinct magnetic sense, it was a very great wonder that there was not. The study of magnetism was a very recondite subject. One very wonderful discovery that was made in electric magnetism was made by Faraday, and worked out very admirably by Foucauld, an excellent French experimenter, showing that a piece of copper, or a piece of silver, fall between the
poles of a magnet, would fall down slowly, as if through mud. Was it conceivable that, if a piece of copper could scarcely move through the air between the poles of an electric magnet, a human being or living creature, in the same position, would experience no effect? Lord Lindsay got an enormous magnet, so large that the head of any person wishing to try the experiment could get well between the poles; and the result of the experiment was marvelous, the marvel being that nothing was perceived. Sir William Thomson, however, was not willing to admit that the investigation was complete. He could not help thinking that the quality of matter in the air, which produced such a prodigious effect on a piece of metal, could be absolutely without any perceptible effect whatever on a living body. He thought the experiment was worth repeating; and it was worth examining whether or not an exceedingly powerful magnetic force was without perceptible effect on a living vegetable or animal body. His own speculations had led him to conclude that there might be a seventh or magnetic sense; and that it was an exceedingly powerful magnetic effect might be produced on living bodies which could not be explained by heat, force, or any other sensation.—British Med. Jour.

The New York Polyclinic.—The order of clinics and courses for the regular term of 1883-'84 is as follows:

Gynæcology.—9 to 10 a. m.: Dr. Wyllie, Mondays and Thursdays, at Bellevue Hospital; Dr. Hunter, Wednesdays and Saturdays, at the Polyclinic.

2 p. m.: Dr. Hunter, Mondays, at the Woman's Hospital.

2 p. m.: Dr. Mundé, Fridays, at Mount Sinai Hospital. 3 p. m.: Dr. Mundé, Mondays, at Mount Sinai Hospital; Dr. Wyllie, Tuesdays and Fridays, at the Polyclinic.

Diseases of Children.—10 to 11 a. m.: Dr. Milbank, Mondays, Wednesdays, and Fridays; Dr. Ripley, Tuesdays, Thursdays, and Saturdays.

Surgery.—11 to 12 a. m.: Dr. Wyeth, Mondays, Wednesdays, and Fridays; Dr. Gerster, Tuesdays, Thursdays, and Saturdays, at the Polyclinic. 2 to 4 p. m.: Dr. Gerster, Tuesdays; Dr. Wyeth, Wednesdays and Thursdays (2:45), at Mount Sinai Hospital. 3 to 4 p. m.: Dr. Gerster, Thursdays, at Mount Sinai Hospital.

Orthopedic Surgery.—9 to 10 a. m.: Dr. Gibney, daily, at the Hospital of the New York Society for the Relief of the Ruptured and Crippled. 3 to 4 p. m.: Tuesdays, Thursdays, and Saturdays, at the Polyclinic.

Bandaging and Surgical Dressings.—8 p. m.: Dr. Crummer, Tuesdays; Dr. Kimball, Saturdays.

Operative Surgery on the Cadaver.—8 to 10 p. m.: Dr. Wyeth, Dr. Gerster, and Dr. Gibney, assisted by Dr. Wardwell and Dr. Pryor, daily.

Diseases of the Skin.—1 to 2 p. m.: Dr. Bronson, Mondays, Wednesdays, and Fridays; Dr. Robinson, Tuesdays, Thursdays, and Saturdays, at the Polyclinic.

Physiological Chemistry.—1 to 2 p. m.: Dr. Fowler, Mondays, Wednesdays, and Fridays, at the Laboratory, 215 East Thirty-sixth Street.

Diseases of the Chest and General Diagnosis.—2 to 3 p. m.: Dr. Leaing, Mondays, Wednesdays, and Fridays; Dr. Hudson, Tuesdays, Thursdays, and Saturdays.

Diseases of the Eye.—2 to 3 p. m.: Dr. Webster, Mondays, Wednesdays, and Fridays; Dr. Grunen, Tuesdays, Thursdays, and Saturdays, and Mondays at 3 p. m., at Mount Sinai Hospital.

Diseases of the Throat, Nose, and Ear.—4 to 5 p. m.: Dr. Elsberg, Mondays, Wednesdays, and Fridays; Dr. Brandeis, Tuesdays, Thursdays, and Saturdays.

Diseases of the Nervous System.—4 to 5 p. m.: Dr. Hamilton, Mondays, Wednesdays, and Fridays; Dr. Gray, Tuesdays, Thursdays, and Saturdays.

Lectures on Orthopedic Surgery.—We would direct the attention of our readers to Dr. Newton M. Shaffer's course of lectures at the New York Orthopedic Dispensary and Hospital, the arrangement of which will be found stated in our advertising pages. For several years past Dr. Shaffer's lectures have proved very acceptable to the profession.

Danger from Flies.—According to the "British Medical Journal," Dr. Grassi is said to have made an important, and by no means pleasant, discovery in regard to flies. It has always been recognized that these insects might carry the germs of infection on their wings or feet, but it was not known that they were capable of taking in at the mouth such objects as the ova of various worms, and of discharging them again unchanged in their feces. This point has now been established, and several striking experiments illustrate it. Dr. Grassi exposed in his laboratory a plate containing a great number of the eggs of a human parasite, the Trycocephalus dispar. Some sheets of white paper were placed in the kitchen, which stands about ten metres from the laboratory. After some hours, the usual little spots produced by the feces of flies were found on the paper. These spots, when examined by the microscope, were found to contain some of the eggs of the tricercophalus. Some of the flies themselves were then caught, and their intestines presented large numbers of the ova. Similar experiments with the ova of the Oxysys serunciularis and of the Tenea solium afforded corresponding results. Shortly after the flies had some muddy cream the Oidium lactis was found in their feces. Dr. Grassi mentions an innocuous and yet conclusive experiment that every one can try. Sprinkle a little lycopodium on sweetened water, and afterward examine the feces and the intestines of the flies; numerous spots will be found. As flies are by no means particular in choosing either a place to feed or a place to defecate, often selecting meat or food for the purpose, a somewhat alarming vision of possible consequences is raised. Dr. Grassi invites the attention of naturalists to the subject, and hopes that some effectual means of destroying flies may be discovered.

The Propagation of Disease by Books.—When preventive medicine is searching out and checking all possible means by which infectious and contagious maladies are spread, the part which books may play in the propagation of disease should not be overlooked. There can be no doubt that the specific contagia of many zymotic disorders, and especially of scarlatina, small-pox, and typhoid fever, in the form of particles of material emanations from the bodies of patients, may attach themselves to the covers and pages of books, and so be carried from the sick to the healthy. In private families, all books and periodicals used by a patient during his illness from a zymotic disease had best be burned upon his convalescence. In general hospitals in which zymotic diseases are treated, scrupulous care should be taken that all literature used by patients suffering from contagious and infectious maladies shall be reserved exclusively for use in the special wards devoted to such disorders. We are afraid zymotic diseases are sometimes spread by books through the agency of lending-libraries and second-hand book-shops; and it would be well if the literature of such establishments were occasionally subjected to efficient disinfection. Persons recovering from zymotic disease should remember that it is one of their duties to take all care to avoid their infection of the healthy, and they should be taught to refrain from handing to others the books they have used during their illness.—British Med. Jour.

The History of Gonorrhoea.—Professor Hamilton, of Aberdeen, whose profound study of the histological conditions in bronchitis well qualifies him for the task, has been enabled to examine microscopically the condition of the urectra in acute gonorrhoea, opportunities for which must rarely occur. The epithelium of the urethra is disposed, much as in the bronchus, in three strata—the deepest of flat cells, the middle of pear-shaped cells, and the superficial of columnar cells. In acute gonorrhoea the process consists mainly in an exaggerated and irregular proliferation of the deeper strata of cells, the cell-proliferation being so rapid that the discharge contains but few of the fully developed columnar forms. The denudation of the surface in this process explains the scabbing pain on micturition. The secretion of the mucous glands is increased, as in bronchial inflammation. There is also considerable corporcular infiltration of the mucous membrane, leucocytes being accumulated in the sub-epithelial lymphatic spaces; and although there does not exist an elastic basement membrane, which Professor Hamilton believes to prevent the escape of these interstitial products on to the free surface in bronchitis, he doubts either if that occurs here, believing rather that the cellular exudations in the meshes
of the mucosa are carried away by the lymph stream. There was not in this specimen any marked congestion of the blood-vessels; and the trabecular tissue of the penis was not abnormal, unless accumulated leucocytes in the cavernous spaces be so considered. Strictures are produced in chronic urethritis probably by the sub-mucous tissue becoming cresosed and contracting upon the lamina, the absence of "fixed joints" indicating the difference in result from chronic bronchitis when the tubes are dilated. The tubules of the testicles and of the epididymis from the same case also showed marked catarrhal inflammation, being filled with débris and epithelial cells in all stages of disintegration; but there was no interstitial inflammation whatever.

The paper is contained in the current number of the "Practitioner," which is also enriched by a very lucid account of the pathology of dropsy from the editor's pen.—Lancet.

The Hay Fever Association.—The "Lancet" seems to imagine that this is an association of gentlemen who make a specialty of hay fever, and proceeds to read its members quite a little homily on the inconvenience of such subtle subdivisions of medical study.

The Sanitary Conference at Rome.—All, the European powers have signified their adherence to the proposal of the Italian government to summon a conference at Rome, with the object of making sanitary regulations, and drawing up an international sanitary code. Signor Manchini, Minister for Foreign Affairs, will shortly address a circular to the powers on the subject.—British Medical Journal.

Antiseptic Frigidity of Wounds.—The healing of open wounds is said to take place more slowly under the influence of antiseptic dressings. It would seem, according to M. Gosselin, that the antiseptic substances exert an antiphlogistic action on open wounds. In preference to speaking of such an effect as antiphlogistic, M. Gosselin would use a new term—frigidity. By frigidity, then, we are to understand the slowness of repARATION and cicatrization of an open wound. In 1879 and 1880 MM. Gosselin and Bergeron showed that antiseptic agents impede the alteration of the blood about wounds, not only by purifying the atmosphere of the gums of putrefaction, but by rendering the extravasated blood less liable to undergo putrefaction. It has been since determined that this change in the blood also takes place within the capillaries, and consists, in fact, in a coagulation of the albuminous material. Weak solutions of carbolic acid, alcohol pure and diluted, and camphorated brandy, all give rise to coagulation of the blood in the capillaries, as well as outside the vessels. The circulation is thereby arrested, and this occurs without any vascular contraction. The stronger the antiseptic solution the more rapidly was the circulation arrested. Moreover, Gosselin believes that this limited amount of arrest in the circulation is not accompanied by any gangrene of the tissues.—Lancet.

Army Intelligence.—Office List of Changes of Officers serving in the Medical Department of the United States Army from October 20, 1883, to October 27, 1883.—Barnett, Richards, Captain and Assistant Surgeon. Assigned to duty at Columbus Barracks, Columbus, Ohio. Par. 1, S. O. 240, A. G. O., October 20, 1883. —Wolverton, William D., Major and Surgeon. Granted leave of absence for one month. Par. 6, S. O. 201, Department of the East, October 24, 1883. —Maas, Louis M., Captain and Assistant Surgeon. Assigned to duty at Fort A. Lincoln, Dakota Territory. Par. 4, S. O. 180, Department of Dakota, October 15, 1883. —Moore, John, Lieutenant-Colonel and Assistant Medical Purveyor. To be relieved from duty as Medical Director, Headquarters Department of the Columbia, to proceed to San Francisco, California, and assume charge of the medical purveying depot in that city. Par. 10, S. O. 243, A. G. O., October 24, 1883. —Horton, S. M., Major and Surgeon. Leave of absence for one month, with permission to apply for an extension of three months. Par. 6, S. O. 216, Department of the Missouri, October 26, 1883. —Merrill, J. C., Captain and Assistant Surgeon. Granted leave of absence for one month. Par. 7, S. O. 201, Department of the East, October 24, 1883.

Naval Intelligence.—Office List of Changes in the Medical Corps of the Navy during the week ending October 27, 1883.—Surgeon W. K. Van Reypen, detached from the Naval Hospital, New York, and ordered to the United States steamer Powhatan. —Surgeon H. M. Wells, detached from the Naval Laboratory, New York, and ordered to the Naval Hospital, New York. —Medical Inspector A. C. Gorgas' orders modified so that he will be detached from the Naval Hospital, Chelsea, Mass., on December 10th instead of November 10th.

Wasing, Eugene, Assistant Surgeon. To proceed to New Orleans, La., for temporary duty, August 2, 1883. To proceed to Mobile, Ala., for temporary duty, August 27, 1883. To rejoin his station (New Orleans) as soon as practicable, September 25, 1883. —Promotions.—Gutierrez, John, Passed Assistant Surgeon. Promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, September 1, 1883. August 31, 1883. —Resignation.—O'Connor, F. J., Assistant Surgeon. Resignation accepted by the Secretary of the Treasury, to take effect August 1, 1883. August 2, 1883. —Appointment.—Wasing, Eugene, M. D., of South Carolina, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, August 2, 1883.

Society Meetings for the Coming Week.—Monday, November 5th: New York Academy of Sciences (Section in Biology); Medico-Chirurgical Society of German Physicians; Morrisania Medical Society (private); Brooklyn Anatomical and Surgical Society (private); Utica Medical Library Association. Tuesday, November 6th: New York Neurological Society; New York Obstetrical Society; Buffalo Medical Association; Elmhurst Academy of Medicine; Ogdenburg Medical Association; Medical Society of the County of Hudson, N. J.; Weehawken Medical Society of the County of Richmond, N. Y. (Stapleton). Thursday, November 8th: New York Physicians' Mutual Aid Association (annual); Society of Medical Jurisprudence and State Medicine; Public Health Association of New York; Harlem Medical Association (private); Brooklyn Pathological Society. Friday, November 9th: Yorkville Medical Association (private); Medical Society of the Town of Saugerties, N. Y. Saturday, November 10th: New York Medical and Surgical Society (private).
Lectures and Addresses.

A CLINICAL LECTURE ON
DISEASES OF CHILDREN,
DELIVERED AT THE VIENNA POLIKLINIK.

By Professor Alois Monti,

The Treatment of Mild Cases of Scarlet Fever.—Rickets with Laryngismus.—General Remarks on the Phenomena of Rickets.

Case I.—This child, gentlemen, according to the father's account, has been sick for fifteen days. The illness began with vomiting and sleeplessness, and then a redness of the skin was noticed all over the body. You observe on the hands the characteristic desquamation which can only result from scarlatina. When you examine the skin, you find that it is unusually dry and scaly. Hence we have scarlatina in the desquamative stage, and this has evidently been a simple case, with no great disturbance of the general system.

What is to be done in such a case? In the first place, it is of the highest importance to examine the urine, as renal complications occur during the third week of the disease. I shall have it done in this instance. This child must go to bed and stay there, taking no food except soups and milk. Such patients should be carefully isolated. If there are other healthy children in the house, they should not be allowed to attend school, but must be kept at home and closely observed. As regards medication, I would insist that there is no specific treatment. You may give whatever you please, it makes no difference with the course of the disease. Attend strictly to the diet, as this is of vital importance. In light cases, renal complications never occur when the diet is properly regulated. Medication does not affect the fever, but, as long as it is present, give nothing but soup and milk.

Examine the urine daily, and as long as it remains cloudy, even if no albumin is present, give no solid food. No meat should be allowed before the fourth week. It has been my experience that all children who take solid food too soon have renal complications, as shown by the appearance of albuminuric, dropsy, etc. After the fourth week this danger is past. The ordinary idea that the use of cold baths, or the so-called "taking cold" from the patient's getting up too soon, is the cause of kidney trouble after scarlatina is erroneous. It is only caused by the premature use of a meat diet. If there is albumin in the urine, keep the patient in bed up to the fourth week. When may you give baths? At any stage. They have no deleterious influence on the kidneys. The only point is not to give them too warm—above 20°–27° C. [=78°–80° Fahr.]

In regard to medicines: In simple cases give nothing; distilled water is as good as anything. But, as you must give something in your private practice, dilute phosphoric acid or carbolic-acid water may be used. This is the only treatment. You will never see dropsy in simple cases under this treatment. This child's urine has now been examined, and found to be normal. The treatment, in short, will be: Keep him in bed, and give nothing but soup and milk.

Case II.—I spoke yesterday of the rachitic changes to be noticed in the skull. In the thorax you will notice enlargement of the heads of the ribs, increased width of the sternum, and, subsequently, sinking in of the thorax on each side, giving rise to the so-called "pigeon-breast." In this infant the process is only just beginning. You can feel the heads of the ribs, which are slightly enlarged. The ribs are curved on one side more than on the other. The vertebrae are normal, but the head shows rachitic changes clearly. The mother says that the child has spasms of the glottis at night. Now, this spasm is a symptom of several diseases, but is not a disease itself. It bears an intimate relation to rickets, and, according as the latter disease progresses or comes to a stand-still, the laryngeal spasms increase or diminish in frequency. Thus, in Vienna, when autumn comes and the child is obliged to be in the house a good deal, the rachitic processes advance more rapidly, and with them the tendency to laryngismus. In summer, on the contrary, when the child is much in the open air, the disease is arrested. This alternation may continue for two or three years. The cause of this laryngeal spasm in rickets has never been ascertained. Some observers maintain that it is due to peripheral irritation in the nervous system; others have sought for an explanation in the possible cerebral changes which may accompany cranio-tabes.

There is no treatment for this laryngeal trouble aside from an anti-rachitic treatment. Regulate the diet. Give milk and soup, and meat if the child is old enough. Cod-liver oil is the most important remedy. I would prescribe in this case:

B. Ol. morrhuae, 1000
  Pulv. acacis,
  Aq. destill., ad, q. s. ad 10000
  Tinet. valerianae, 200

M.

Sig. Three teaspoonsfuls three times a day.

Give the child a salt bath at least three times a week. When a spasm occurs, open the window and give the patient air. It is a good plan also to sprinkle cold water on the abdomen. By seizing the tongue with two fingers and pulling it forward, we elevate the larynx, and thus stop the attack.

Case III.—This child, the mother says, suffers from cough and dyspnea. The temperature of the skin is evidently elevated. On examination, we see that this is a beautiful example of rickets affecting the entire skeleton. The thorax is short, with a well-marked "rosary"; there is a slight angular curvature of the spine. Even the clavicles, you see, are bent. Feel of the scapulae; they are abnormally thickened. There are characteristic epiphyseal swellings on the extremities. Notice the pelvis, how small and narrow it is. The child is five years old, and yet he is not larger than one of two years. On standing him up, see how peculiarly the pelvis slants forward. The trochanters are unusually prominent. The thighs bend outward; hence the knees are thrown inward (guin valgum), and a result-
ing forward curve appears in the tibia, in consequence of which he has flat-foot. All of these changes result in regular sequence from the pelvic deformity. The arms are, in like manner, bent and distorted; in fact, there is hardly a bone in the whole body which remains unaltered. As a result of the disease, the child is thin and badly nourished. The abdomen is prominent. On examining the throat, we find that the neck is larger than normal, and that a catarrh is present.

In connection with this case I should like to speak a little further of the symptoms of rachitis, of which you have seen such a good example. As a result of the thoracic changes, the lungs themselves may be affected. Rhachitic children are very prone to catarrh and pneumonia. If the rachitis ceases to advance, the pulmonary symptoms may disappear; but, if the disease continues, the pulmonary centers become cheesy. In every case there is enlargement of the spleen, varying in extent with the progress of the disease. Examination of the blood shows nothing unusual, though in some cases leucocytosis may develop. The urine is generally of low specific gravity, the phosphates are frequently in excess, and I have found lactic acid, but not often. The most important systemic disturbances are those in the alimentary organs. The appetite is poor, with dyspepsia, gastric pain, and vomiting. The stools are irregular, sometimes loose, and sometimes the contrary. Analysis of the faces shows an excess of lime.

Meteorism is a constant accompaniment of the digestive troubles. So long as the latter continue, we may be sure that the rhachitis is progressing. Notice carefully the general condition of the child’s nutrition, and let him be weighed at regular intervals. Lay it down as a cardinal rule that, as long as the patient wastes, the disease must be advancing. Fever has been stated to be a symptom of progressing rachitis. I have often noticed it in such cases, but it has always been due to some complication, not to the affection itself.

As regards the course of the disease, I would say that it begins in the head or thorax, and may either be limited to one of those regions or affect the entire skeleton, as in the case which you have seen. It is important to be able to tell in a certain case just when the changes began. During the first few weeks of infancy the head is first affected; at three or four months, the thorax; between the ages of two and three years, the long bones begin to show evidences of rachitis. The time of the normal growth and development of the bones determines the time at which they may be affected. From this you will see that it is important to notice whether the head alone is involved, or several of the bones.

Bleached Sponges. — It is quite commonly supposed that the bleached sponges which can be seen at nearly every street corner in the baskets of itinerant vendors have done service at some one of the hospitals, and have been cleansed and bleached to supply the demand of those who prefer a cheap article. Although this impression is probably an erroneous one, the public should nevertheless avoid using, for bathing purposes, sponges that have been “chemically treated” in order to render them white, as instances have been reported of serious inflammation of the eyes caused by their use.

Original Communications.

THE IMPORTANCE OF
CLEANLINESS IN SURGICAL OPERATIONS.*

By R. STANSBURY SUTTON, A. M., M. D., PITTSBURG, PA.

In years prior to 1838 no germ theory of disease existed. It has had its growth within the present generation, and is far from fully developed at the present time. Earlier surgeons did not annoy themselves with visions of bacteria-clouds and micrococci-colonies. Legs were amputated, arteries tied, bones excised and reseected. Many died of infection, many survived. That the statistics in reference to this matter have improved with the growth of the germ theory, and the practice of the antisepptic system, there can be no reasonable doubt.

But, while modern surgeons have attained better results, it is entirely probable that the germ theory is, in some respects, badly understood, and that our application of chemicals for the destruction of bacteria and micrococci is too wholesale, and often more detrimental to the wounds and the patients than the germs they are supposed to destroy would be.

In times gone by, a great amount of dirty and careless surgery was followed by good results — a proof of itself that all matter out of place, which we call dirt, was not a poison to the wounds infected. What is ordinarily termed dirt may or may not be pernicious. It may even be antiseptic. In proof of this, we have antiseptic soils, as, for instance, the peat so often now used for surgical dressings.

And it is a fact that in this city of Pittsburgh the dirtiest portions are the most exempt from epidemics of infectious diseases. It would appear that we lack discrimination in reference to this matter of what is and what is not really dirt. Many have attached too much importance to the microscopic inhabitants of our world; and some even argue as if the Almighty had put us on the earth for the express purpose of destroying bacteria in our lungs and stomachs, and of being in turn destroyed by them. In short, they have gone wild on the subject, and are only now learning that many, and, indeed, nearly all of these little organisms are innocuous; that only some varieties are malignant.

Much is being learned; and, while the germ theory of disease is in the main correct, we shall ere long better understand how to apply it to practice in surgery, and know better where and what to combat. Some germs are dangerous, some are not. In late years I have known two doctors to grow very ill after cutting their corns. One was a regular, the other a homeopathic doctor. The former died, the latter survived. Both had cut their corns with a dirty knife. Fus was the element which had dried upon the blade, and begat a bacterium that did the business for one, and nearly for the other. When the old surgeons cut open an abscess, wiped off the knife upon a towel, then gave the knife a rub or two over the leg of their pantaloons before putting it away, this was considered pretty clean work. But, if the

* Read before the American Academy of Medicine, October 10, 1883.
next fellow, who had a boil opened with that knife, died, death from natural causes was the verdict, and the comment followed that all surgical operations were "ticklish things." It was not the pus on the knife that poisoned these doctors; it was the germs of bacteria lying dry there, and which were planted in a soil suitable for their development. They had developed in the pus, and were ready for planting. Pus injected directly into the blood-vessels has by Chauveau been proved incapable of producing pyaemia when the pus is fresh or so-called healthy pus. Virchow substantiates this view in proving that pyaemia is not thus produced.

The pus must contain something else—a poisonous germ or element. It grows from exposure of the pus to the air, and possibly from other conditions.

One day I saw Lawson Tait open a belly, seize a Fallo- pian tube full of pus, and, in trying to draw it out of the wound in the belly-wall, the sac ruptured, and the pus ran over the woman's intestines and trickled away down into her belly. I drew a long breath; the idea that the woman would soon develop a peritonitis was in my mind. She didn't do anything of the kind; she got well, and did it in good style. That "something"—that bacterium or villainous micrococci—wasn't in that pus. One drop—yes, one one hundredth of a drop—of some pus in that woman's belly would have killed her. All fluids are not noxious, even if purulent; all germs are not malignant. Besides, all the germs fatal to one animal may be innocuous to another. This has been well established. A few years ago, while on a shooting expedition, I fell in with an intelligent fellow whose profession was spaying hogs and cattle. He had done one thousand ovariotomies among hogs with scarcely any loss. I learned that he was going to operate, at the farm I was staying at, the next day. I postponed my morning hunt and observed him.

The hogs were put into a dirty pen, caught one by one, and held on the side. The fellow's hands were dirty, his tools no better, his ligatures ditto. He cut the hogs, took out the ovaries and tubes, à la Lawson Tait, put one stitch in the wound at its middle, and turned the hogs loose in the dirty barn-yard. I was there for some days later. Those hogs all did well. Had they been human subjects, they would certainly all have died. Living tissues combat noxious germs and destroy them. More is this the case in some animals than in others. Lister believed in noxious germs, and originated much of the so-called antisepic method. Through it surgery has shown better results, and it is quite possible, almost proved, that the cleanliness insured by the method is all that is in it. While this is true, it does not follow that germsicides will not yet be found better than carboic acid, etc., and free from the objections now pertaining to some—that of being poisonous to our patients. We are told that the alimentary canal is full of bacteria, that often a large proportion of the fecal matter consists of bac- teria alone. In London I saw Mr. Allingham doing many operations in the rectum. He used no carboic acid or other germicide. I said to him: "Do you do operations at the opening of a sewer without antisepic precautions?"

"Yes," he replied, "and the wounds do very well. Some- how or other the intestinal variety don't injure the wounds."

So we are told that those bacteria infest all the openings of the body. The dentists don't seem to be much troubled about them. Their tooth pulling is rarely followed by trouble. All germs are not malignant, and the great probability is that very few germs are. These latter we must look out for, and, to make ourselves safe, we must wage war against all germs. If a surgeon ignores all cleanliness he will come to grief; but, if he is clean in every detail, carboic acid will not likely do much for him, unless he operates in the pus-soaked wards of some old hospital, where he had better adhere closely to Listerism, spray and all. Carboic acid is not a reliable germicide, and sometimes poisons the patient. Iodoform is a good germicide, but also a poison.

Bichloride of mercury will kill bacteria when diluted to the extent of one part of the salt to 330,000 parts of water. It is the coming agony on this subject. We shall see. Yet something for spray must be found; carboic acid is of no use, water is just as effective as a germicide, for no bacteria are killed, in the short time a spray is playing, by a five-per-cent. solution of carboic acid. Wet germs stick to the surface they lie on; therefore wet the floor and the walls, and, if you like, wet the air, with a spray of water or carbolized water, but keep it off the wound. It is good for nothing. Spray has had its day; irrigation with carbolized water will stand much longer. The carboic-acid (a three-per-cent. solution) water, if it stands made for a few days, may be depended upon for purity, and a stream running through a wound will cleanse it, lessen bleeding, and make it easier to operate. But the water must be from twenty-four to forty- eight hours old, or it may contain living bacteria, and spores may live in it for a week. Iodoform is a more reliable germicide, but it is very poisonous, and must be carefully handled inside of the belly.

What precautions should we observe independent of chemicals in surgical operations? The place of operation should be free from carpet and curtains and upholstered furniture. The floor should be well scrubbed, the walls also, and both should be wet at the time of operation. No dust can therefore be disseminated through the room. The patient should be scrupulously clean as to clothing and covers. The parts to be operated upon should be well scrubbed with soap and water, and shaved with a clean razor. Tow- els wrung out of boiling water should be laid about the area surrounding the part. Thus the place for the wound and surroundings are rendered aseptic.

The operator, assistants, and nurses should wear clothing free from blood-stains or splotches of pus, and which has never been worn about infectious cases of disease. They should cut and clean their nails, and scrub their hands and arms with soap and water and dry them upon clean towels. The instruments to be used should have been scrupu- lously cleaned with turpentine or alcohol, then with soap and water, and should lie in pans which were filled with boiling water sufficiently high to immerse all. The water will cool sufficiently to proceed by the time all is ready.

The ligatures should also be scalded in the same man- ner, and used directly from the bath. No one but the oper- ator should handle the instruments if possible, and they
THE PATHOLOGY OF ACUTE LOBAR PNEUMONIA FROM A NEW STANDPOINT.

BY WILLIAM D. SCHUYLER, M. D.

Fourth Article.

An Outline Scheme of the Developing Local Process.—The Rationale of the Process.

(Concluded from page 500.)

The inference to be derived from the limitation and possible size or very small holding capacity of a single receiving space into which exudation is poured is, that when exudation begins to form in one of them, it must almost immediately fill it, especially as this exudation, as we have seen, occurs under and from pressure. And for an equal reason the consequent effects to be noticed hereafter must occur with like rapidity. Furthermore, as we may infer from the comparison of strength and possible resistance, already given, when exudation begins, the process of consolidation, in a general sense an entire consolidation, may be, as it frequently is, rapid and quickly completed.

I may say that it is mainly by the aggregate action of the immense numbers of separate consolidations, "pneumonic granules," within its structure that the lung involved is solidified and distended. Some distending action, however, may result from developing epithelium. As this source of development and distension is not noticed by some pathologists, and as it occurs late in the process in yellow consolidation, when exudation proper is complete, such effects must be slight and unimportant in comparison to those of the essential pneumonic exudate.

In order to appreciate all of the effects of exudation, it is important to bear in mind or understand (1) that it is derived from the blood in the branches of the pulmonary artery (Flett); and (2) that it is comprised of elements of the blood. That the pneumonic exudation is blood, probably somewhat altered relatively by pressure and the straining process to which it has been subjected, also by having been obstructed nutritively, will be apparent, first, by its behavior and course—including its immediate solidification by coagulation, its early and rapid degeneration, liquefaction, and subsequent complete removal, in which (course) it exactly resembles that of blood when from any cause that fluid becomes extra-vascular; second, that it is blood further, and I may say conclusively, shown under histological considerations of morbid anatomy, given in a subsequent chapter, already referred to, the support therein being mainly derived from authorities cited.

The several results of exudation as it escapes from the vessels, and is received, retained, and solidified, in an extra-vascular, terminal air-space, are, 1, a filling of this very small cavity until it is distended to its utmost capacity; 2, the formation, pari passu, of pressure within this space and upon its walls, notably of lateral pressure upon the vessels, in the alveolar walls and in the alveolar septa; and, 3, the depletion of the systemic blood in volume equal to the quantity of the exudate.

a. The general gross aggregate of these effects is as follows: Of the multiplied formation of the individual coagulates, 1, the solidification of the lung structure, as stated. As a single coagulate distends an individual space, so the aggregate structurally, and, as we shall see, completely, distends the organ throughout the area of the process and constitutes the consolidation of the pathology. 2. Of lateral pressure upon the vessels (owing to the amount of the exudate, its immediate coagulation, and the small holding capacity of the alveolar space), there results, first, their support against further distension and possible rupture; second, as the coagula grow, they compress the distorted, varicose vessels back into normal outlines and position; and, thirdly, by the pressure and counter-pressure of their continuing complete formation they cause the complete closure of the capillaries involved. This general closure of the capillaries throughout the area involved by the process is rendered readily probable by the delicacy of their walls and a consequent inability of the vessels themselves to offer resistance.
also by the readiness with which their previous blood contents is evacuated. At the moment exudation begins, in the stage of engorgement, the involved capillaries are congested, filled to their extreme limit of distension, as will be shown later, with obstructed blood. Before the exudate can compress these vessels, or pari passu, their contents must be discharged. This discharge is accomplished partly by exudation itself and partly by displacement, the contents by the latter method being moved forward into the efferent vessels by the lateral pressure of the exudate. Evacuation by exudation is direct, and calls for no explanation; and, by displacement, is readily accomplished, for two reasons, namely: 1, because the congesting, obstructed, intra-vascular blood does not coagulate; and, 2, because the internal capillary coat is unimpaired by the process. For which reasons its evacuation by a forward movement is readily accomplished, especially by a properly applied, and, as pointed out, a developed external, lateral force.

That this blood does not coagulate we have among others the evidence of Delafield ("Studies in Path. Anat.," New York, 1882), who says: "In earlier stages of red hepatization... although the blood-vessels are full of blood, it is not coagulated." Also that it is readily displaced throughout is evident from the well-known and often verified fact that the vessels of the pneumonic lung may, with no considerable effort, be injected with an artificial preparation post mortem, death occurring at any stage of the process. Furthermore, the readiness and ease with which these vessels may be injected demonstrates the second point claimed—that the intima, their internal coat, is uninjured structurally throughout, and that their structural potency is preserved to the end. This latter fact is of interest in connection with the teaching that in croupous pneumonia, the acute lobar we are studying, the involved capillaries are closed, destroyed, by an intra-vascular, endothelial, inflammatory cell proliferation, and are subsequently reformed (Heitzmann), and must conclusively negative such a result.

The contents of these capillaries being readily removable, as shown; that the resulting lateral pressure of the exudate, aided by exudation direct as an action, is adequate to cause their evacuation, is evident (1) from the anemia which exists, as we shall see (study of morbid anatomy), throughout the period of complete consolidation; (2) from the obstruction to general circulation which exists at this time during consolidation, and (3) from the degree of intra-organic distension, and hence pressure, to which the lung is subjected by an acute pneumatic solidification, which distension is said by some to equal a full inspiration. By others (Aitken, Wilson Fox), the organ has been found so swollen, distended, as to entirely fill the costal cavity, as shown by exhibiting the marks of the ribs when removed from the chest.

The probability of a simple, mechanical, non-inflammatory closure of these capillaries by the resulting pressure of the forming and solid exudate is evident, partly from the fact that obstruction exists while consolidation is perfect, and partly, furthermore, by the additional fact that it is relieved when softening of the consolidate, in the course of its degeneration, reaches a point at which pressure ceases to be adequate to shut out a further passage of the blood, which, as we shall see, occurs just prior to the crisis of the process or of its resolution. The phenomenon of this renewal of the circulation could scarcely be attributed to a possible vascular reformation. That a capillary structure so extensive as becomes implicated and closed in acute lobar pneumonia is destroyed by inflammatory action and again renewed (according to the author of this theory, to wit: "a great many capillaries are destroyed, for the nearer the process approaches to gray hepatization the fewer are the capillaries to be seen in the alveolar walls,"—Heitzmann, "Microscopic Morphology in Health and Disease. Croupous Pneumonia," pp. 719)—especially at the time reconstruction must occur, if at all, about the period of crisis, when many subjects who ultimately recover are quite moribund from asthenia, and others are too feeble from age to support such an extensive reformation of vascular structure, especially through a region practically tied up by the consolidate and by its pressure, and, therefore, most feebly supplied with imperfectly oxygenated blood—is scarcely possible. It is much easier to believe that the vessels "which can not be seen in the alveolar walls in complete gray consolidation" are simply closed by pressure; especially as the course of the exudate, its effects by development and softening, quite conclusively account for the pari passu phenomena of circulation. That anemia exists during complete consolidation will be shown farther on, and that such a state is due to pressure is conclusively evident.

b. The general vascular effects due to exudation in this process are most important as regards the conservative character already claimed for it. They are (1) depletion of the volume of the systemic blood in amount equal to the entire weight of the exudate, including that which is expectorated and retained—the latter forming the consolidate; and (2) the restoration of an equalized and non-injurious, non-pathological blood pressure throughout the systemic and pulmonary vessels.

The importance of the effect of depletion as a conservative action will be appreciated only when we consider the relative amount of the entire blood thus lost, as estimated in the manner above stated. The weight of the expectorated exudate I do not find to have been computed. While expectoration varies greatly, in many cases it amounts to half a pint, a pint, or even more. Add this quantity, however, to the weight of the consolidated exudate, which has been estimated by comparing, with due precaution, the weight of the consolidated with the unaffected lung, and I found to amount anywhere up to two pounds if a single lobe is affected, and to four or even five pounds when an entire lung has been involved (Flint, Styles, Grisolle), and the total loss must amount to from one sixth to one third the entire amount in the body.

Considering, furthermore, that the nutritive functions are quite inhibited, as we have seen, while obstruction is present, and that therefore little increase or renewal of the vital fluid can arise from this source, the proportionally large amount of depletion which takes place can but have a markedly inhibiting effect upon the process in progress. The conservative action of this great depletion is manifest
throughout the second effect noted—namely, that of restoring an equalized blood pressure throughout the systemic and pulmonary circuit; and especially as annulling the local afferent pulmonary morbid fulness and pressure which developed on account of the obstruction resulting while the blood volume was greater than could readily pass through the functionally diminished pulmonary capillaries.

It has been set forth that the development and extension of the pneumatic process depend upon and are the result of (1), and directly, a created capillary insufficiency more or less limited or extended; and (2) a consequent resulting, abnormal and greatly and rapidly increased intra-vascular local afferent blood pressure, which creates a further and extending capillary insufficiency, and is the important cause of the process, or, more especially, of its extent as it is subsequently developed. I may state here that, could the circulating blood be withheld from entering and aggregating in the insufficient capillaries as a result of their atony, and approximate pressure thereby be prevented, there would not result a pneumatic process; the affected capillaries would soon recover their tone, and no inconvenience would be felt. As a suggestion, I question whether under some conditions of temporary debility and low blood pressure such an occurrence may and does not take place.

But a process once developed through pressure, by the depletion which results from exudation, the blood volume, which makes pressure possible, is naturally reduced until the diminished remainder can and does pass the uncomplicated and available pulmonary vessels without stress or delay. In which way and by which process that which could not be anticipated and prevented—the occurrence of a resulting morbid intra-capillary blood pressure immediately following the initial lesion—is now accomplished through exudation and the completion of the necessary supporting anatomical process, and it renders a further extension or consolidation impossible. Excepting from some added cause an extension of the primary lesion—viz., the creation of a more extended capillary functional insufficiency—occurs, when a further like consolidation may result or not, according to the resulting disturbance of pressure which may be possible and is created.

c. A description of the local vascular effects, noticed as the third division of the results of exudation, has been anticipated in the foregoing. They are, (1) in regard to the involved, affected atomic and distended capillaries, their support, restoration to normal outlines, and, later, their complete closure; (2) in a general pulmonary sense, the consolidation and distension of the involved structure, with a resulting intra-organic pressure; (3) the creation of a consequent anaemic condition throughout the region consolidated; (4) cessation of the action of morbid development; and, (5) except in a histological sense, a repose of the organ as anatomically involved.

Syphilis in the Tropics.—At the recent meeting of the International Congress of Colonial Physicians, held at Amsterdam, M. Catrin, of the medical corps of the French army, dwelt upon the special severity of tertiary syphilis in hot climates. In 182 cases there were 52 of perforation of the palate. In general, he thought syphilis was most severe where malaria was most intense.

ON THE SO-CALLED EQUINE SCARLATINA.

By FRANK S. BILLINGS, Vet. Surg., BOSTON.

I have been asked to write a paper on this disease. There is no such disease. It has been, and is still, the misfortune of veterinary medicine to be a sort of tail attached to human medicine, a parasite which depends on the latter for strength and support. In the early days of veterinary medicine the nomenclature of the human branch was transferred without reflection to the diseases of animals, as the micro-pathological anatomy of the organs of man has been, and is to-day.

Then we have the "measles" of the hog. Who would for a moment think this was not measles at all, but a cysticercus invasion? We speak of "hog cholera," which bears no relation to the human disease; of the "typhus" of various animals, when nothing resembling the typhus of man, in its peculiar microscopic phenomena, has ever been seen. "Typhoidal" phenomena are common enough in all species of animals, but not those peculiar to typhus.

Veterinary pathologists (we never had one—though many books have been written, we never have yet had a logical, skeptical thinker, as a writer on pathology in veterinary medicine) have yet to learn what constitutes the essentials that should give an animal disease the same name which it occupies in human nosology. To give an animal disease the same name attached to a human disease which it resembles, it must have:

1. The same cause, and be equally transmissible between man and this animal species.
2. Having the same cause, its genus must be similar.
3. The principal points of its pathological anatomy must be similar.
4. It must be similar in course and termination.

These may not be all the points of resemblance, but they are the cardinal ones, and are only slightly modified by the varieties of constitution, anatomical structure of parts, etc. For instance, pneumonia is pneumonia wherever you find it, and so of every organic disease, and in general we have pretty nearly the same varieties in animals as appear in man; but it is singular that the different varieties which occur, under varying circumstances, in man never appear in the same course in our animals, viz.: Broncho-pneumonia is the rule in the horse, cheesy pneumonia in cattle, and catarrhal pneumonia in the dog.

As to "scarlatina," to be such in fact, the first necessity would be that it was transmissible in some way from man to the horse, and vice versa. This is not the case. It has not one characteristic in common with the disease in man, except that there is a cutaneous eruption. The name has been entirely dropped from all the modern continental works on zoopathology, and never appears in any of the medical periodicals, except those of English origin.

What is known as "scarlatina" is either a condition following on the "influenza diseases," or a new malarial complication due to some new contagium, which the anticipating disease had prepared the way for. It is nothing but a
modified form of what is known as "purpura" in English veterinary works, and occurs under exactly the same conditions.

My exact meaning will become clearer to medical readers if I quote from Williams, the best English author. He says: *

"A febrile disease, characterized by an eruption of the skin, petechial spots on the nose, soreness of the throat, and sometimes suppuration in different parts of the body, particularly the submaxillary space."

"Unlike the scarlatina which attacks man, it is a non-contagious disease, generally attacking but one or two horses in a large stud, among which some form of epizootic disease is at the time prevalent."

"Scarlatina is usually associated with epizootic catarrh, and occurs in animals that have been for some days suffering from that disease; and the production of such an alteration in the blood as induces the scarlatina is due to defective ventilation or stable drainage, or to overworking, by which the air becomes loaded with decomposing animal matter. Sometimes a weak constitution will convert a catarrh into scarlatina, and the severity of an epizootic disease may alter the blood and give origin to scarlatina."

This is from an author who has been called a "world-renowned pathologist." If it is pathology, if there is a grain of logical sense in it, except that the condition the author calls a disease comes as a sequel of something else, then I do not know the use of language.

The A B C of zoopathy has yet to be written.

Clinical Reports.

NEW YORK HOSPITAL.

CLINICAL REMARKS BY ROBERT F. WEIR, M. D.

October 20, 1883.

TWO CASES OF INTERNAL URETHROTOMY.

Gentlemen: The patient before you is a seaman, forty-eight years of age, who contracted his first gonorrhoea thirty years ago. Eighteen years ago he sustained an injury of the hip and an internal injury causing bloody urine. A physician at that time told him he would be obliged in the future occasionally to pass an instrument through the urethra. Hence it may be inferred that the urethra was lacerated to some extent. Three years afterward he was operated upon by external urethrotomy, and was given an instrument which he was told to pass. This he did for a time, and then, as usual with such patients, neglected it. He is positive the size of the instrument was No. 10 English. Finally, about six months ago, a No. 6 was the largest that he was able to pass. Then further neglect on his part took place, and subsequently more or less complete retention occurred several times. At present I find a stricture three inches from the meatus, admitting a No. 6 French—a stricture which has not yet been operated upon; and at the site of the old stricture, now retracted, is another narrowing. The scar of the operation is seen in the perineum. Now, you might suppose that when external urethrotomy was done, the entire depth of the urethral wall, and, of course, of the striated portion, being divided, recontraction would not take place; and, as a rule, up to a certain limit, that limit being the normal size of the urethral canal, the more thorough the division the less likely is recontraction to take place, or at least to take place so soon. Division up to the normal size—sufficient to admit No. 32 French will do, as a rule—is as effectual by internal as by external urethrotomy, and it is much safer. Statistics show that dilatation is but little safer than internal urethrotomy, and, as the latter gives more permanent and quicker results, I shall resort to it on this occasion. I have some specimens here showing the small amount of spongy tissue in the upper as compared with the lower wall of the urethra. You will see that the resistance to the cutting blade due to the firmness of the fibrous bands is much greater at the lower than at the upper stricture, from the fact of its traumatic origin. The division is effected with Maisonneuve's urethrotome, and afterward the front stricture, which has not yielded sufficiently, is enlarged with Otis's instrument.

In the case of the second patient, who contracted his first gonorrhoea eighteen years ago, the stricture is situated about four inches from the meatus, and admits of a No. 12 French bougie à boule. There is no deeper stricture. I call your attention to a little point shown in the examination—the peculiar appearance of the oil injected after it has become mixed with the mucous of the canal; it looks very much like the secretion of a chronic ulcer, and might lead one to a false diagnosis. The stricture is now divided, first with Maisonneuve's and then with Otis's urethrotome. The latter was too large for introduction at first. Should hemorrhage occur, it can be controlled in the anterior portion of the canal by a bandage wrapped snugly about the penis; in the peno-serotal portion, or in the perineum, by pressure exerted upon a perineal pad by a rubber bandage attached to a belly-piece.

Both of the patients will receive an eighth of a grain of morphine every two hours and five drops of the tincture of aconite the first day, the further administration of these drugs to depend on whether or not a chill attends the passage of the urine. Sounds will not be passed for two or three days, and then only if the temperature of the body is normal, after which they must be used regularly—at first by the surgeon, and finally by the patient.

Book Notices.

Of all recent contributions to literature with which we are acquainted, "English as She is Spoke" is the one most vividly brought to our mind by this coruscation of scientifical light. In inaudible ambition, in the temerity born of conscious fitness to execute and accomplish, and in general self-complacency, the authors of these two little books are one.

We feel that the interests of Mr. Hudson and our readers will best be served by a few morceaux taken from the index of this remarkable pot pourri.

BOOK NOTICES.

[ N. Y. Med. Jour.,

516

The unusual impartiality and evident conscientiousness of this inquiry ought to forward in a measurable degree the clearing of the turbid vivisection question. Previous arguments, either for or against experiments upon living animals, appear to us to have been nugatory, mainly for want of that sympathetic appreciation of opponents' motives which is essential to the adjustment of differences of sentiment.

Although "Philanthropos" is by tacit confession a working physiologist, the claims of the anti-vivisectionist to a respectful and even deferential hearing have never before been as generously and feelingly recognized by one so successful in placing the advocate for regulated experiment in an absolutely unsailable position. But, while we very willingly make this acknowledgment, we yet feel that "Philanthropos's" altruism needs extension. The able chapter on "Our Rights over Animals" we would gladly have seen supplemented by a longer chapter on The Rights of Animals to our Sympathy and Protection. The oneness of nature, the common brotherhood, not only of men, but of all living things, which is the most resplendent discovery of modern science, urges upon us, with an impassioned argument more forcible than untroubled sentiment, to admit the right of life to continue, and the claims of sentience to our tenderness. The highest gift of man is not his fortissimo supremacy in the order of organic nature, but what is literally its appanage—a proper sense of the responsibilities of that supremacy.

Under the heading, What is Pain? the physical basis of this subjective state is interestingly and instructively illustrated, and the question is considered from an aspect commonly ignored by anti-vivisectionists—the relation of pain to complexity of nervous organization. The question, What is Cruelty? is answered from a cognate standpoint. The infliction of pain is justifiable or unjustifiable according to circumstances. "Pain given for the good of the individual itself may be unjustifiable if the good to be obtained is not sufficient." And "long life, mental and bodily activity and health, are benefits which in quality more than balance the evil of pain." Succeeding chapters are occupied with "The Relation of Experiment to Physiology," "The Relation of Medicine to Experiment," "Legislation: Past, Present, and Possible," and there are forty-four pages of appendices.

Those who would be fortified, not only with the facts, but the logic of this subject, or dispossessed of unreasoned feeling against vivisection, should turn to the work of this singularly competent writer.

In these days of cheap medical literature it is actually a relief to the eye to see a book handsomely printed on thick paper with wide margins, no matter what it may contain. The contents of this one are worthy of the form in which they appear. Though nominally a second edition, it is actually a new work, being a consolidation under a new form, and with additions of the author's previous works "On the Treatment of Fractures" and "On the Treatment of Wounds." But, as the author says, "Wounds are fractures, and fractures wounds; differing in the situation and density of the structures involved, but essentially solutions of continuity, similar in causation, in processes of physiological repair, and in surgical treatment."

The gist of this whole book is to be found on page 286:

"That infection is always floating in the atmosphere, ready to settle, in the shape of impalpable and implicable germs, into any breach which may be made in the surface of a living body, is an idea which has never troubled me. The prescription, inspired by that idea, to rub strong carbolic acid into the innermost recesses of a compound fracture, to pursue and kill the germs; the warning that an antiseptic dressing may lose all its potency through a hole no bigger than a pin's point, in the investing Mackintosh, admitting countless germs; that a dressing must be changed as soon as a little discharge permeates it, lest a septic channel be established for the ubiquitous and maleficient vibrios; these will settle down, as a swarm from the air, on a granulating sore, if the spray be not kept in action while it is dressed, are—I say it with the sincerest respect—questionable propositions."

It is well known to the readers of Mr. Gangee that to him these propositions are no longer questionable. He simply does not believe them. He rejects a system of surgery founded on Pasteur's theory of germs. He believes in antiseptics simply up to the point of perfect cleanliness, and for his own part he prefers dry dressings, drainage, and rest for the treatment of all wounds. He has been, and is now, perhaps, the strongest advocate of these views, and the cases and clinical remarks which make up this very instructive and readable book are intended to teach, among other general principles of surgery, what may be done by simple methods of wound treatment. The time has been during the past few years when he has stood almost alone in advocating and practicing these principles.

It is needless to go into details over the cases themselves. They are interesting records intended for students, drawn from a large surgical practice, and much valuable information is conveyed by them in a colloquial form.
CORRESPONDENCE.

The object of this little work is to place on record the statistics of the Montreal General Hospital in reference to the operation of excision of the knee joint. Of the twenty-eight cases, a majority have been treated by the author, a number by Dr. Roddick, and a few by others. Only one ended fatally (from pyemia), and in two the limb was subsequently amputated. In one of these amputation was done because the patient insisted upon it, and in the other the patient contracted small-pox, and amputation was rendered necessary by suppuration. There were only four cases in which the shortening reported exceeded two inches, and in three it was less than one inch.

The point of individuality in the author's method of operating consists in so sawing the surfaces of the femur and tibia that the former shall be convex and the latter concave, the one fitting into the other. By this simple measure he obtains perfect apposition and more satisfactory union.

LETTER FROM WASHINGTON.

The Naval Medical Society.—Physicians in Civil Life and those in the Government Service.—The District Medical Association.—The Medical Society.—Mr. Graham Bell and the Rev. Dr. Gallaudet on the Education of Deaf-Mutes.—Dr. Sternberg on Bacteria.—The Forthcoming Report of the Surgeon-General of the Navy.

WASHINGTON, November 6, 1883.

The Naval Medical Society, which is now well advanced in the second year of its existence, has become a decidedly pros- perous body, those medical officers who are stationed at a dis- tance furnishing a large proportion of the papers at each meet- ing. At the last meeting, which occurred on the evening of November 1st, there were more papers than could be disposed of before ten o'clock, and the number present was almost larger than the Library of the Museum of Hygiene could accommoda- te, including visitors from the army and the district society.

The papers of the evening were: 1. A Report upon the late Epidemic of Yellow Fever at Pensacola, by Dr. D. M. Guiteras, accompanied by some typical temperature charts. 2. An Instance of Defective Plumbing, observed in his own house, by Dr. J. H. Kidder, the instance being the omission of a portion of the ventilating pipe, which should have communicated with
the soil-pipe; followed by some remarks by Mr. Robinson, the Inspector of Plumbing, upon the recent improvements made in the methods of inspection in the district. 3. A paper by Dr. John C. Wise upon the Treatment of Fractures of the Forearm, illustrated by a case occurring in his practice, and recommending the practice of extension in such fractures, as well as in those of the lower extremity. And, 4. A Report of a Remarkable Case of Double Aneurism of the Aorta, by Dr. J. H. Bryan. One of the aneurysmal dilatactions in this case had caused extensive absorption of one of the dorsal vertebra, and another had opened into the oesophagus by adhesion. Two of the papers were from out-town members, and all called for animated discussion.

There is a pretty broad difference in this city between medical men in civil life and those who are connected in one way or another with the Government. Some years ago the difference almost reached the gravity of a discussion, owing, I suppose, partly to the easy good nature of some army and navy surgeons, who were willing to practice medicine occasionally outside of their proper and limited sphere, but found that want of use had blunted the edge of their keenness in demanding fees. Taking into consideration the army and navy, the Marine-Hospital Service, and the many department clerks who have been at one time or another qualified practitioners, the number of those who can afford to compete with struggling practitioners upon these terms is so considerable that it would not be strange if there should grow up a distrustful attitude on the part of those who must live by their profession as well as in it. Quite recently I hear that there was introduced into the District Medical Association a resolution to the effect that those members of the association who become clerks, or engage in any business other than the practice of medicine, shall become, ipso facto, associate (i.e., non-voting) members. I mention the resolution (which, by the way, has not yet been acted upon) as illustrating the peculiar constitution of the medical association and society here, and not in a critical spirit. Indeed, the hypercritical might fail to see where the punishment is, etymologically speaking, of being made an associate member of an "association."

The association is not a medical, but an "ethical" body, to which every candidate for the advantages of medical converse must get admission before he can hope to belong to the medical society proper. The result is a very compact body, comprising most of the reputable practitioners of the district, whereby the code of ethics is maintained in a degree of absolutism not to be matched in many cities. The society is both kindly and liberal in admitting honorary members to a share in its discussions, but the platform of active membership is only to be reached through the narrow gateway of the association, after an extended probation.

But the medical man living in Washington who loves the mental friction of his fellows need not be confined to the medical society. Besides the Naval Medical Society, already mentioned, there are the Biological and Philosophical, meeting on alternate weeks, and sometimes even more interesting than the strictly professional gatherings.

Last Saturday night, for instance, at the Philosophical Society, a discussion between Mr. A. Graham Bell and Dr. Gallaudet on the subject of the education of deaf-mutes was so very entertaining that I am tempted to enlarge upon it somewhat, although it is not strictly a medical subject. Both speakers have a rare gift in expressing their thoughts extemporaneously, and both had very distinctly a message to deliver, with enough divergence in the purport of their messages to make the discussion lively and interesting. Beginning with a pretty close adherence to his text, "Some Fallacies relating to Deafness," Mr. Bell was led almost insensibly, as it appeared, into condemnation of the use of the sign language as a means for the instruction of those deaf from infancy. Dr. Gallaudet, as the President of the Kendall Green Deaf-Mute College, could scarcely do less than take up the cudgels in behalf of a system which is there largely practiced. As to cogency of argument, the honores were pretty equally divided; but it was noticed that, however the speakers might differ as to the value of the sign language in instructing the deaf, they both afforded striking though unconscious examples of the value which they attached to lively gesture, as illustrating and re-enforcing the power of speech.

On Friday last week, at the Biological Society, Dr. Sternberg lectured upon bacteria, using the proof-sheets of a work he is about to publish (upon malaria), and treating more particularly of the classification of the order, and the light thrown upon the same by the results of culture experiments made by himself and others.

The forthcoming Report of the Surgeon-General of the Navy is likely to attract much more of the general attention than commonly falls to the lot of official documents. It begins by stating that the present system of annual statistical exhibits of the health of the navy began with the report issued in 1880, and that a uniform system of tabulation has now been perfected which will, in a few years, afford a valuable mass of facts bearing upon the geographical distributions of disease and its relations to age, food, clothing, and the altogether exceptional nature of the floating habitations in which it occurs. In the British naval medical reports, where a settled and continuous system of tabulation has prevailed since 1837, the advantages of large aggregates, as furnishing data for studying the sanitary conditions peculiar to sea life, are very apparent. Our own reports heretofore have consisted of individual impressions and experiences published from time to time in a fragmentary form. The tabulated reports already issued under the present system cover 54,616 cases, an aggregate as yet too small, in the opinion of the Surgeon-General, for advantageous condensation or for a statement of general results.

He recommends that the medical departments of the great naval powers be invited to a conference, with a view to the adoption of a uniform nomenclature, classification, and tabulation of diseases, and, as well, of a system of interchange of periodical reports of the movement of disease, from which international reports of sanitary conditions all over the world may be published at stated intervals. It already appears that there are periods of accession, climax, and decline, followed by intervals of comparative immunity from disease, all over the world. "Are these variations due to some mysterious general cosmical conditions developed contemporaneously in various quarters of the globe, or to waves of morbidty arising in certain localities and successively invading others at remotest points?"

Adverting next to the Naval Hospital system, he is of the opinion that some of the existing buildings no longer fulfill the requirements of modern sanitary science; few are eligible situated, and all are too large and costly for present or probable future needs. Two of them (Chelsea, Mass., and Brooklyn) are in enclosures which are much too large and have materially appreciated in value. He therefore recommends that the establishments at Chelsea, Brooklyn, and Philadelphia be sold, and the proceeds turned into the Naval Hospital fund, from which the money was drawn to make the original purchases; that this fund be invested in Government securities, the interest on which will go far to make the system self-supporting; and that, instead of the establishments so disposed of, station hospitals be built at convenient points, suited to the needs of the locality and of the service, and intended for the accommodation of acute cases only. The cost of these station hospitals he estimates at fifteen
thousand dollars each. Chronic cases and those likely to be of long continuance are to be sent to a general hospital at a central point. For the central point he recommends Norfolk, as being in a mild climate, easily accessible at all seasons, and provided already with extensive grounds and suitable buildings. At the central hospital there will be an average of from five hundred to six hundred patients, affording exceptional advantages for the clinical instruction of the younger medical officers. Hither he would transport also the manufacturing and distributing laboratory now in New York, and the fifty or so insane patients usually in the Government Asylum at Washington. The establishment, if all of General Washington's plans be carried out, will correspond, with several advantages, to those now in operation at Netley and Toulon.

The Washington Hospital, he recommends, should be turned over to the Museum of Hygiene, which has proved to be a gratifying success, and which has long since overflowed the banks of its contracted quarters. The library has grown to about six thousand volumes, and is especially rich in sanitary and nautical literature. The experiment of establishing libraries of reference at all stations, and circulating medical libraries in all fleets, has also proved to be a success, and will be continued.

In general, the Report has much of the wit of brevity, and its recommendations are bold and far-reaching. I think them to be both wise and well-considered; but, when so many vested interests are attacked at once, it is inevitable that there will be active opposition, and, very likely, attacks of a more or less bitter kind. An inference which may be said to draw itself is that, unless the present Surgeon-General should be reappointed, neither report nor recommendations are likely to bear fruit.

LETTER FROM LONDON.

The Remains of Harvey.

LONDON, October 20, 1883.

Since the turbulent times of the Chamberlains, when the Royal College of Physicians concerned itself more, so far as the public could perceive, with furthering the material interests of physicians as a class—the word "physicians" being taken in its strict English sense, excluding surgeons and general practitioners—than with the promotion of medical science, it has gradually been settling down more and more to the latter course, until of late years it has performed its appointed functions almost unnoticed in this great center of trade. Rarely, in recent times, have any of its acts or any of its purposes (if, indeed, it has entertained any purposes apart from contributing to the great and ever-present work of helping the progress of our art along) occupied the attention of men outside its own limits, or, at all events, outside the profession. An instance to the contrary has lately occurred, and one which, as it is suitably noticed by the secular press, is likely to win for the college the credit of having done a graceful act of reverence to the memory of one of its most illustrious fellows.

I refer to its transfer of the remains of the immortal Harvey to a sarcophagus of its own provision. For more than two hundred years the remains of William Harvey had slept, "laid in lead," in the family vault in a dilapidated country church. In the course of these many years the casing itself had come to share in the decay manifested in the surroundings. The vault has been visited from time to time by various members of the medical profession, and they have not failed to notice the encroachments of time upon the sufficiency of the leaden case. Openings were found in it, and it is said that on one occasion a visitor was astonished to see a toad hop out from one of these holes. Whether or not this incident was the starting-point of the movement of the College of Physicians looking to a more adequate provision for protecting the remains, I can not say, but it is well known that for some time past the college has been desirous of obtaining permission from the Harvey family to furnish such provision. The members of the family are understood to have hesitated to grant the necessary permission, feeling, quite naturally, that it was their own duty and privilege to take whatever measures might be necessary. Finally, however, they yielded to the wishes of the College of Physicians, and the result has been the transfer of the remains from the vault to the Harvey Chapel above, where they now rest in a handsome sarcophagus provided by the college.

The ceremonies accompanying the transfer took place day before yesterday—St. Luke's day. The choice of that day seems to have been doubly fitting, since it is not only the day commemorative of the medical apostle, but also, as one of the memorial tablets in the chapel recounts, the anniversary of the day on which a member of the Harvey family was killed in battle. Proceeding to Hemstead, a small and obscure village in North Essex, where the Harvey family settled, the representatives of the college joined with those of the family in the simple but touching formalities. Among the medical men present, either officially or otherwise, were Sir William Jenner, Dr. H. W. Acland, Dr. George Paget, Dr. George T. Fincham, Sir Andrew Clark, Dr. F. W. Pavly, Dr. Wilson Fox, Dr. Farre, Sir Henry Pitman, Dr. Allehin, Dr. Munk, Dr. Henry Monro, Dr. C. B. Radcliffe, Dr. William Wood, Dr. Graily Hewitt, Dr. Alfred Meadows, Dr. Douglas Powell, Dr. W. G. Hunter, Dr. Broadbent, and the bearers, Sir Richard Bennett, Dr. Owen Rees, Dr. Sieveking, Dr. Quain, Dr. B. W. Richardson, Dr. Dyce Duckworth, Dr. Norman Moere, and Dr. Shepherd. The remains were borne from the vault round to the porch of the church, and thence into the chapel. The leaden case had been restored to its original condition so far as possible, and, enclosed therein, the remains were committed to the sarcophagus. A short service having been said by the clergyman, the president of the Royal College of Physicians deposited a copy of Harvey's works, in Latin, published by the college in 1766, together with photographs of the church and the following record written on parchment:

The body of William Harvey, "laid in lead," simply soddened, was laid, without shell or inclosure of any kind, in the Harvey vault of the church of Hemstead, Essex, in June, 1657. In the course of time the lead inclosing the remains was, from exposure and natural decay, so seriously damaged as to endanger its preservation and render some repair of it the duty of those interested in the memory of the illustrious discoverer of the circulation of the blood. The Royal College of Physicians of London, of which corporate body Harvey was a munificent benefactor, and which by his favor is the possessor in perpetuity of his patrimonial estate at Burmarsh, Kent, did, in 1882 and 1883, by permission of the representatives of the Harvey family, undertake that duty. In accordance with this determination, the leaden mortuary chest containing the remains of Harvey was repaired, and, as far as possible, restored to its original state, and on this 18th of October, 1883, in the presence of three representatives of the Harvey family and of the president, the office bearers, and many other fellows of the Royal College of Physicians (whose names are hereunto subscribed), was reverently translated from the Harvey vault to this sarcophagus, raised by the college for its reception and preservation.

Two years ago the tercentenary of Harvey's birth was celebrated by the erection of his statue at Folkestone, where he was born, and now this tardy attention to his remains at Hemstead crowns all that it has seemed well to do to insure, not the perpetuation of his memory, for that is imperishable, but a closer connection of our feelings with the man himself, in place of a vague sentiment concerning the discoverer of the circulation.
THE ACADEMY OF MEDICINE IN IRELAND.

It is but a few months since we chronicled the amalgamation of the various medical societies of Dublin into one organization entitled the Academy of Medicine in Ireland, and now a handsome volume comes to us giving the "Transactions" from December, 1882, to and including May of this year. Although originally formed of four Dublin societies, the Medical, the Surgical, the Obstetrical, and the Pathological, and although its membership is drawn largely from Dublin, we observe in the list of fellows and members the names of a number of gentlemen living elsewhere in Ireland, and even in other parts of the United Kingdom. It may be that these gentlemen were already members of one or another of the component societies; at all events, the plan of not making residence in Dublin necessary to membership must be allowed to be a good one. The tendency of our societies here is to impair their usefulness by narrow geographical limitations. We have before alluded to this fact with regret.

It may be remembered that, at the time the formation of the Academy of Medicine in Ireland was under consideration, about a year ago, one or two of the Dublin societies hesitated to sink their own autonomy by joining in the scheme. It is easy to understand a certain sentimental unwillingness of this sort, but it is hardly to be supposed that the feeling will linger long, even if it has not already died out. The individuality of each of the original societies survives, to all reasonable intents and purposes. Each has become a section of the Academy, choosing officers and holding meetings of its own, and each Sectional Council is entitled to two representatives in the General Council, besides its president and secretary. Combined, the representatives of the sections far outnumber the other members of the General Council, which manages the business of the Academy.

In addition to the due weight thus secured for the preferences of each section in matters affecting the general working of the organization, provision is made against evisceration of the scientific work. For example, it is stipulated in the Rules that no pathological specimen shall be exhibited at any section other than the Pathological, except by card; and such exhibition does not preclude any subsequent communication regarding the specimen at the Pathological Section.

There is one feature that strikes us as odd—namely, that the meetings are virtually private, although any fellow or member may introduce two visitors by cards obtained from the Sectional Secretaries, and a medical officer of the army or navy is entitled to admission on presenting his own card. No doubt the meetings are thus practically open to the profession, and under-graduates may become Student Associates, but it is not easy to see why there should be any restriction. Any physician is admitted without question to the meetings of our public societies, and we have yet to hear of any objection to the practice. It is quite practicable to restrict the membership without excluding any one from the meetings.

Besides the four sections, there are two sub-sections—one of Anatomy and Physiology, and one of Public Health. There is also a Committee of Reference, answering to what we commonly call a pathological committee. All things considered, the organization of the Academy of Medicine in Ireland seems to have been carried out in a way calculated to promote effective scientific work. If any proof were needed that such has been the case, it might be found in abundance in the volume of "Transactions."

An analysis of the contents of the volume, based on the proportion of work done by the several sections, would scarcely show the relative amount of consideration given to medicine, surgery, obstetrics, pathology, public health, and anatomy and physiology, for in one instance a paper that ought properly to have come before the Surgical Section was read before the Medical Section—a paper on the Successful Removal of a Laryngeal Polypus by Voltolini's Method. Moreover, as is the case with our Pathological Society, the work of the Pathological Section does not seem to have been at all confined to pathological discussion, but to have turned upon anything that happened to be illustrated by a specimen; consequently the proceedings of that section may be said to furnish but little if any indication of the degree to which strict pathological inquiry has been pursued by the Academy.

The fifty-one papers include eighteen read before the Pathological Section, eleven before the Surgical, ten before the Medical, seven before the Obstetrical, four before the Sub-section of Public Health, and one before the Sub-section of Anatomy and Physiology. Not only were more papers read before the first-mentioned section, but its proceedings take up nearly one third of the entire volume. Concerning the value of the papers published in the first volume of the Academy's "Transactions," it must be said to be very great. It is only to be regretted that the discussions also are not given.

The preponderance of ostensible over real pathological work in an organization of this sort, made up of the practitioners of an English-speaking country, it would probably be very difficult to do away with. There is enough of the realistic about a morbid specimen to keep the attention from flagging, and yet it seldom stimulates a meeting to pathological study. It is not at all certain, however, that the opposite state of things is desirable. The pursuit of pathological investigation is necessarily a work for individuals, and not for assemblages.

WILLIAM HARVEY.
reached only by dint of the most persevering and original research, we can scarcely wonder that Dr. William Harvey is known, so far as he is known at all to the world at large, as the discoverer of the circulation. It is in the nature of things that he should be so known, and the fact is not to be regretted, but it is to be hoped that the recent ceremonies attending the commitment of his remains to a more fitting receptacle than the rude and dilapidated casing in which they have slept for more than two hundred years—an account of which is given by our London correspondent—will have the effect of drawing attention anew to the real splendor of Harvey’s genius, by recalling the contrast between his great discovery and a mere discovery in the ordinary sense of the word.

Servetus had, it is true, already demonstrated the lesser circulation; but the blood was still supposed to be carried from the liver to the heart, which, in turn, distributed it to the body through the veins, the arteries being held to be only the channels through which the numerous hypothetical entities grouped under the term “spirits” were conveyed to the various parts. Not only Servetus, but Realdus Columbus and Casalpin, had stood on the verge of the grand induction made by Harvey; but it is none the less puzzling to speak of the latter as having simply given the finishing touch to their labors. On the contrary, difficult as it is for us, with our present knowledge, to realize how they could fail of the final step in the theory of the circulation, it reflects all the more lustre on Harvey’s sagacity that he was able to take firm hold upon what had been almost within their grasp.

But, grand as the generalization was that embodied Harvey’s great discovery, and admirable as the course of research, the patient observation repeated again and again, was by which he arrived at it, the discovery itself was not his greatest achievement. Indeed, had he failed to make it, he would yet have rendered its speedy attainment a certainty, for he established and inculcated methods of study that could not fail to lead to it. But, not only were those methods calculated to secure this single result, they were such as to carry an influence far beyond the scope even of so important an element in animal physiology as the circulation of the blood. It is safe to say that it was not our understanding of the circulation alone that was assured by Harvey’s investigations—in every nook of the great field of biology they were felt as an impetus and a guide; their impelling energy has been at work ever since, and their guidance has never failed. They gave the coup de grâce to the spirit of speculation and plausibility, and established exact observation and critical interpretation in their place.

With all our veneration for Harvey’s genius, let us not forget that it was in Italy that he studied anatomy, under Fabricius, where, it is not ungenerous to suppose, he took in the rudiments that he afterward developed into such a shapely structure. In his native land he met with honor, it is true, but not, we must infer, until he had battled for several years with incredulity, for his work, entitled “Exercitatio Anatomica de Motu Cordis et Sanguinis Circulatione,” was first published, not in England, but in Frankfurt.

Harvey’s achievements appeal not only to the professed investigator, but to the physician. He was not a man of leisure; he had no fund, either of time or of money, at his command, and no elaborate outfit. He was a practitioner of medicine, vexed with the every-day worries that are the common lot of our profession. Let the lesson be drawn that there is no man too much immersed in affairs, too much taxed in matters of detail, to give some share of his attention to endeavors to aid in the advancement of the sciences on which medicine rests.

THE COUNTY MEDICAL SOCIETY’S ANNUAL PRIZE.

We are not without hope that one good effect, quite apart from the question of ethics, may turn out to have been wrought by the gathering of so great a number of the members of the Medical Society of the County of New York as was witnessed on the occasion of the annual election of officers last month, for many of those present probably learned for the first time, as they listened to Dr. Purdy’s report in behalf of the Committee on Prize Essays, that there was such a thing as a prize offered by the society. The result will be, we trust, that some of those gentlemen, having been brought to realize the fact, will enter into competition for the prize in the future.

It must be on account of the absence of any wide knowledge of the opportunity that for the past two years the committee has not felt itself warranted in awarding the prize. This year but one essay was sent in, and that was so inferior in quality, the committee reported, that it failed utterly to deserve recompense. Much the same report had to be made the year before.

The conditions of the prize should be generally understood. It is an annual prize of a gold medal, of the value of one hundred dollars, to be awarded to the author of the best essay on any medical subject, provided any one of the essays is judged worthy of the award. The competition is open to all the members of the society.

It seems discreditable that two years should have passed without any essay worthy of the medal having been presented. The intrinsic value of the prize is small, it is true, but that is a matter that scarcely counts for much among the considerations that ordinarily induce men to compete in this way. A successful essayist wins the respect of many who perhaps never knew of him before, not only in the society itself, but among the profession at large, by the publication of the essay. The society’s membership is very large—not far short of a thousand—and surely there ought to be many of its members with sufficient ambition and ability to make a creditable contest every year.

MINOR PARAGRAPHS.

THE INDEX-CATALOGUE.

The fourth volume of the “Index-Catalogue of the Library of the Surgeon-General’s Office” closes with an entry of the works of Antonius Fizes. This shows the rapid progress that is being made in this great work, and the appearance of the volume reminds us anew of the heavy obligation under which the profession rests to Dr. Billings and his coadjutors. We can only repeat all that we have heretofore said in praise of the undertaking and
the way in which it has thus far been carried on. When we consider the size of these volumes, and the sort of matter that makes up their contents, the promptness with which they succeed each other becomes little less marvelous than their fullness and accuracy.

THE ARMY MEDICAL LIBRARY AND MUSEUM.

It appears by the annual report prepared by the late Surgeon-General Crane, for the year ending June 30th, that 3,912 volumes and about 5,000 pamphlets were added to the Library of the Surgeon-General's Office during the year, making the entire collection now about 60,900 volumes and 68,700 pamphlets. To the Army Medical Museum 628 specimens were added, 94 by purchase, and 544 by gift. The report renewes the recommendation for a fire-proof building for the library and the museum.

A NEW TREATMENT OF CHOLERA.

A new and, we must say, somewhat imaginative correspondent of the "Lancet," proposes to treat cholera patients by injections into the bladder. He alludes to the empty and contracted state of that organ in cases of cholera, and to the small opportunity there is for injecting any noteworthy bulk of liquid (liquid being what is wanted) under the skin or into the veins. He is not unmindful of the feeble absorbent power ordinarily manifested by the bladder, but believes that the case would be different in cholera patients. Intra-peritoneal injections, he thinks, ought not to be used until after experiments on a large scale have been made with the lower animals. To the latter caution he might have added that one desideratum is a method of injection that will enable the operator to perforate the parietal peritoneum without also plunging his instrument into the visera.

NEWS ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending October 30, 1883:

The Academy of Medicine.—At the next meeting, to be held Thursday evening, the 15th inst., Dr. Francis Deafeld will read a paper on Typhoid Fever in New York. It is expected that Dr. Loomis, Dr. Draper, Dr. Janeway, Dr. A. A. Smith, and others will take part in the discussion.

The New York Polytechnic.—Dr. Lewis S. Pitcher, of Brooklyn, gave a lecture before the surgical class on Friday of last week, on the Mechanism, Diagnosis, Pathology, and Treatment of Fractures of the Radius near the Wrist Joint.

The Woman's Medical College of the New York Externaty.—Dr. William Oliver Moore has been appointed professor of diseases of the eye and ear, in place of Dr. Charles Stedman Bull, resigned.

The Medical Department of the University of Georgetown.—Dr. John B. Hamilton, the Surgeon-General of the Marine-Hospital Service, has been elected professor of surgery.

A SANITARY CONVENTION will be held at London, Ontario, on the 14th and 17th inst., under the auspices of the Provincial Board of Health.

The late Professor William H. Byford, Jr.—The following resolutions have been adopted by the faculty of the Minnesota College Hospital:

Resolved, That as it hath pleased a loving and gracious Father to permit Dr. Byford, after a long and protracted period of great suffering, to lay gently down the burden of life; that in his early death the college to which he was devotedly attached suffers the great loss of an efficient, wise, and honorable instructor, whose efforts in its behalf and in the cause of medical education in general were constant and always marked by that wisdom and culture which are born of a wide experience and a liberal mind.

Resolved, That all his intercourse with his friends and professional brethren was marked by a high sense of honor and courtesy, and in his early and sudden death we lose a wise counselor and helpful friend.

Resolved, That we deeply sympathize with his bereaved and sorrowing wife, with his honored father and afflicted family in this their great sorrow.

Resolved, That a copy of these resolutions be sent to his bereaved wife, his sorrowing father and family, and that copies be sent for publication to the local papers and prominent medical journals.

OBITUARY NOTES.

Professor Depau, of Paris.—The death is announced of M. J.-A.-H. Depau, who for twenty-one years past has been a professor of obstetrics in the Paris Faculty of Medicine. M. Depau was born at Pan, in 1811, and received his medical education in Paris. He was made a member of the Académie de médecine in 1852, and has been a prominent and energetic participant in many of the debates held in that body, not only on obstetrics, but on many other topics, especially vaccination. It was he who took the leading part in securing a recognition in France of the danger of vaccinal syphilis and of the importance of animal vaccination. He also was conspicuous in maintaining the equine origin of the cow-pox. He was the founder of the "Archives de toxicologie," a monthly journal of obstetrics and diseases of women and children, and the author of several monographs in obstetrics, notably a treatise on obstetrical auscultation and a clinical work on obstetrics.
amount of suppuration. The wounds healed in from four to six weeks. He had since used this dressing in a number of cases, and with greater satisfaction than any other application. He had also used it in the case of granulating surfaces following burns, and had found that it diminished the amount of granulations, the contraction of which, when they were allowed to develop, was the chief source of deformity. In neither children nor adults had the dressing caused the slightest toxic effect.

The Diagnosic Value of the Bacilli of Tubercle.—Dr. Austin Flint stated that he had lately made the Bacillus tuberculosis in sputa a subject of clinical study, with reference especially to the diagnosis of pulmonary phthisis; and, as illustrating the value of the presence and the absence of this micro-organism, he related the following cases: The first case was that of a woman, over sixty years of age, who had had cough and expectoration for a considerable period. The physical examination rendered it probable that phthisis existed, but the proof was not positive; there was room for supposing that the case might be one of bronchitis and emphysema. Microscopical examination of the sputa showed the presence of bacilli.

The second case was that of a patient advanced in years, who had long suffered from cough and purulent expectoration. The physical signs rendered chronic bronchitis with dilated bronchial tubes probable. The microscopical examination of the sputa showed very few bacilli.

The third case was that of a woman, forty years of age, suffering from aphonia. She was examined in the summer, and the result was negative as regards the physical signs of phthisis; but the aphonia continued, and the sputa were examined with reference to the question whether the aphonia was nervous or phthisial. No bacilli were found, and the patient had since fully recovered her voice.

The fourth case was that of a woman, about forty years of age, who had repeatedly had small bronchial hemorrhages, always at the time of menstruation, which was normal. She had had no cough, but she was very anxious as to the possibility of the existence of phthisis. The physical examination of the chest was negative, and no bacilli were found in the sputa, which, being very small in quantity, were obtained with difficulty.

In two cases there were positive signs of phthisis, but the disease was not advanced. The patients had gained in weight, and the symptoms, together with the physical signs, were such as to lead to the belief that the disease was not progressing. Examinations of the sputa, however, showed the presence of bacilli, but in only moderate numbers.

The last case mentioned was that of a woman, forty years of age, who had had cough and expectoration for more than three years. She was considerably emaciated and enfeebled. The last winter and spring months were passed in Colorado. Before going there, she had hectic paroxysms, the expectoration was abundant, her appetite was poor, and her condition seemed to offer little in the way of a favorable prognosis. The improvement in Colorado was marked; she ceased to have paroxysms of fever, her appetite improved, she gained in weight, and there was notable improvement in the pulmonary symptoms. A physical examination of the chest, after her return from Colorado, showed solidification and cavity, but repeated examinations of the sputa were negative as regarded the presence of bacilli. Taking this latter fact in connection with the co-existing symptoms and the history, it seemed fair to conclude that the tuberculous disease in this case had ended, and that the patient was now suffering only from the lesions which were produced by the disease.

These few cases were related as illustrations. Dr. Flint added that, so far as his experience had gone thus far, it confirmed the value of the presence of bacilli in the sputa as positive proof of phthisis, their absence being of more or less value in the exclusion of phthisis, and the value of their abundance or scarcity, as bearing on the question of whether the disease was or was not actively progressing.

Dr. Flint stated that the microscopical examinations in these cases had been made by Dr. Welch and by Dr. William H. Flint.

Dr. Post asked Dr. Flint whether he considered hemoptysis occurring at the time of menstruation as less significant of phthisis than when it occurred at other times.

Dr. Flint replied in the affirmative. Patients without any affection of the lungs were known sometimes to have hemoptysis at the time of the menstrual flow; but this was less likely to occur than where the flow failed to appear.

Acute Yellow Atrophy of the Liver.—Dr. Francis Delfield gave the history of a case as follows: The patient was a woman, twenty-nine years of age, who entered Bellevue Hospital on the 29th of September. Three weeks previously she had been seized with headache, vomiting, prostration, and pain in the epigastrium. After three or four days she became jaundiced, the urine was high-colored, and the feces were of a clay color; there was absence of fever. She continued in this condition until her admission, at which time there was considerable jaundice, nearly everything taken was vomited, she complained of a good deal of pain at the epigastrium, the urine was high-colored, and the bowels were constipated, but what was passed was clay-colored. There was not very much prostration; there was no emaciation, no febrile movement, and no cerebral symptoms. The patient seemed to have been suffering from the ordinary jaundice which accompanies gastro-duodenitis. She died well until the 5th of October; the vomiting ceased entirely, but some jaundice still remained. On the 6th of October she was not quite so well; she again began to vomit. On the 7th vomiting became much worse, the jaundice was more decided, the temperature rose to 100° F., cerebral symptoms developed, and there was delirium alternating with semi-coma; the urine for the first time contained albumin in addition to bile pigment. The liver was distinctly diminished in size, and, on the 8th, the diminution was still more marked. The temperature ranged from 100° to 101°, the patient was still comatose or semi-comatose, and in this condition she died on the 9th of October. At the autopsy the liver and the kidneys showed the typical lesions of acute yellow atrophy. The liver weighed one pound and three quarters; it was soft and mottled red and yellow; the hepatic cells showed the regular changes, as did also the kidney tissue.

Mastoiditis following Diphtheria.—Dr. T. M. Markee presented a case of bone of considerable size, discharged in the course of suppurating mastoiditis following diphtheria. The case occurred in the practice of a physician in the country, who stated that the patient began immediately to recover after the discharge of the piece of bone, and suggested that trepanning might haveproved of benefit.

Peat as an Absorbent Dressing for Wounds.—The Chairman made some remarks upon this subject, suggested by those of Dr. Post on substrates of bismuth. Peat had been largely used as an absorbent dressing for surgical wounds by European operators, and, having received a supply from Dr. Nemer, an assistant at Esmarch's clinic, Dr. Sands had been testing its value at the Roosevelt Hospital during the past six months. It had proved superior in some respects to all other dressings which he had before used. Notwithstanding the bulkiness of the dressing, it could be neatly adapted to the surface, and be comfortably worn by the patient. In order to develop its absorbent qualities to the best advantage, the peat re-
quired to be moistened, the solution commonly used being the bichloride of mercury. It would then take up seven or eight times its weight of fluid. It was applied in bags of suitable size and shape. The value of this form of dressing had been well illustrated in a case of white swelling of the wrist, in which it was found necessary to excise all but two of the carpal bones, and to remove the extremities of the radius, ulna, and several of the metacarpal bones. The operation was very long and severe. Care was taken to irrigate the wound with an antiseptic solution during the operation, then to insert a decaledified-bone drainage-tube, and finally to apply the peat dressing, which was allowed to remain for three weeks without being changed. Meanwhile the patient was perfectly comfortable and free from pain and fever. When the dressing was removed, the drainage-tube was found to have been absorbed, no suppuration had taken place, and the wound had healed, except one small granulating surface. More recently Dr. Sands had excised the elbow joint for ankylosis, in the case of a child upon whom he had done a similar operation previously. The first operation was followed by profuse suppuration. In the last, in which the peat dressing was used, the wound healed without suppuration. Formerly the pad used with Lister's dressing became impervious and foul. The dressing being porous, the secretions from the wound were quickly absorbed, and, appearing at the surface evaporated, leaving the pad almost entirely dry, instead of accumulating beneath the dressing, as often happened when this was made of a less absorbent material.

Dr. Robert F. Weir confirmed the statements of the Chairman with regard to the value of the peat dressing, and said that a more carboneous and a more perfectly antiseptic form of the material was now being used at Kiel. Lately, "wood-wool" was employed as a dressing for wounds, by mixing one part of black peat with four of the ordinary kind, by Bruns and Czerny, and he himself had found it of excellent service in a number of cases in which he had tried it at the New York Hospital. This wood-wool was primarily manufactured for conversion into paper. Its absorbent property was even greater than that of peat, the latter being capable of absorbing nine times its weight, while the former would absorb thirteen times its weight. Dr. Weir thought, however, in his recent visit abroad, that the best results, with the quickest union, were obtained in wounds by Schade, of Hamburg, who used the finest jute as a dressing, and made it a rule not to allow it to remain on longer than a week or ten days. Absolute rest was enforced even in the case of comparatively simple wounds, and in each instance the entire limb was immobilized until the dressing was changed, when the wound was almost certain to be found completely healed. It was interesting to note the march of surgical methods in different places; for instance, in the north of Germany, notably in Hamburg, Kiel, and Berlin, at present the bichloride of mercury was being largely resorted to as an antiseptic, while in southern Germany, especially at Billroth's clinic, iodoform was chiefly employed.

Absorption of Carbolic Acid.—Dr. A. B. Ball reported a case of poisoning by a very small quantity of carbolic acid. The patient, a boy fourteen years of age, had been operated on by Dr. Sands for empyema, a free opening for drainage having been made under Lister spray, and a peat dressing applied. Three weeks before, when the peat-bag was received from Germany, it had been sprinkled with carbolic acid, and at the time of its application retained a slight odor of the acid. On the morning following the operation, Dr. Ball found the boy's mother in great consternation over the almost completely black appearance of the boy's urine. No other symptoms of carbolic-acid poisoning were noticeable. As it seemed very improbable that the discoloration of the urine was due to inhalation of the carbolic-acid spray, the peat-bag was suspected, and was found to have a faint, but distinct, odor of the acid. After removal of the bag, the dark color of the urine disappeared entirely within the next twenty-four hours. On the establishment of the drainage-opening, air had entered the pleural cavity freely with each inspiration, and thus air, which had been carbolized by passing through the peat-bag, had been presented constantly to a large absorptive surface.

Dr. Weir remarked that the peat or wood-wool dressing was particularly efficacious after operating in empyema, from the great absorbing power. He also remarked that pure carabolic acid injected into a hydrocele sac produced no unpleasant symptoms, had never in his experience been followed by coloring of the urine or other signs of systemic absorption, and always cured the disease. It probably acted as a caustic, immediately destroying the absorbent power of the surface with which it came in contact.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

A regular meeting was held October 25, 1883, the President, Dr. Tyson, in the chair.

The Pathology of Phthisis and its Laryngeal Complications.—Dr. Seiler read a paper on the pathology of tuberculosis and phthisis and the laryngeal complications of the two diseases. He defined tuberculosis as a self-infectious disease, manifesting itself primarily by the production of minute noxiously infected tubercles, which rapidly underwent retrograde metamorphosis ending in caseation, being due to the dissemination of infectious material throughout the lymph channels. This infectious matter was the product of serofolaceous inflammation, and it might remain encapsulated for a long period. He then described the histological characteristics of tubercles, and showed how they might produce consolidation of the lung tissue by exciting secondary inflammation. He defined phthisis as a progressive consolidation of the lung tissue, due to a more or less localized inflammation affecting primarily the splices, followed by retrograde metamorphosis. He thought the different forms and stages, as described by many authors, were merely differences in the severity and extent of the ulcerative process. As etiological factors, he mentioned the various causes of lowered general vitality, predisposing the respiratory organs to chronic inflammation, including heredity, peripheral nerve irritation, hypertrophic nasal catarrh, insufficient atresia of the blood, etc. Improving the general vitality would prevent an outbreak of the disease, and lead to recovery where too much lung tissue had not been destroyed. Such improvement was to be brought about more by proper feeding and exercise in the open air than by the use of drugs. On the other hand, tuberculosis was always fatal, and treatment was of no avail; but a good deal could be done to prevent the formation of the cheesy deposit by improving the health of serofolaceous patients early in life, thus preventing the subsequent outbreak of tuberculosis.

The laryngeal complications of both diseases were then considered in detail, and their differences were pointed out. He stated that the laryngeal lesions never appear prior to the lung disease in phthisis; that they were characterized by a peculiar pallor of the mucous membrane; the tumefaction generally affected the posterior portion of the organ, and the ulcerations were shallow and had a tendency to spread on the surface, and tubercles or cheesy deposits were never found in the tissues of the larynx. In tuberculosis, on the other hand, tubercular deposits had been found in the larynx prior to the lung complications; the mucous membrane was of a livid red color; the tumefactions were more commonly observed in the anterior portions of the larynx: and the ulcerations were deeper, with raised edges, and often extensive destruction of tissue.
Dr. Seiler closed with the remark that the indiscriminate use in our literature of the terms phthisis and tuberculin in referring to lung disease was calculated to mislead the student, and made careful investigation into the pathology and etiology of these diseases extremely difficult, if not impossible.

Dr. J. C. Wilson, in response to a call by the President, said that he had listened with interest to the reading of the paper. The field covered was too great to permit a detailed discussion of the principal points. Two points, however, appeared to warrant comment:

First, Dr. Seiler had several times made use of the expression "tuberculous material not derived from the exterior." If he had understood the paper, Dr. Seiler had not indicated his views as to the nature and source of this "tuberculous material"; and he asked if Dr. Seiler followed the older doctrine—that of Buhl—or if he had some new theory as to the etiology of tubercle?

Secondly, Dr. Seiler failed to make clear his means of recognizing tubercules, either clinically or in the laboratory. It would be of interest to hear his views upon this vexed question. In a recent work, Hamilton, of Aberdeen, again sought to establish a histological criterion for tubercle—the presence of giant cells under a peculiar arrangement. The pathological points were the modes of degeneration—1. caseous; 2. fibrinous. To the latter Dr. Seiler made no allusion. He thought, further, that sufficient emphasis had not been laid on the presence of tubercle in the various forms of phthisis as seen in post-mortem examinations. He heartily concurred in the hopeful views as to the curability of certain forms of chronic lung disease when treatment was instituted at an early period. Nothing had exerted a more unfavorable influence upon the therapeutics of such diseases than the false view that the constitutional tubercular diathesis invariably antedated the local lesions of pulmonary consumption.

Dr. F. P. Henry remarked that Dr. Seiler's paper was so comprehensive that he found it impossible to refer to more than a few of the points contained in it. He was not inclined to draw so broad a line of distinction between that form of pulmonary disease in which miliary tubercles predominated and that in which the deposit was in larger caseous masses. Like Dr. Seiler, he was by no means convinced of the primary importance of the bacillus as a cause of tuberculous, but he was inclined, however, to attribute it to a prominent part in the production of the secondary symptoms of phthisis—those of systemic infection—which are largely septate in character. The symptoms of interference with oxidation, caused by even extensive destruction of pulmonary tissue, were subordinate to those of systemic infection caused by absorption of the contents of cavities. The presence of the bacillus in the contents of these cavities was indispensable to the production of changes capable of producing this systemic infection. A small ulcerating cavity communicating with the absorbent vessels was more disastrous in its effects than a larger cavity shut out from the absorbents by a lining membrane or wall of fibrous tissue. He understood Dr. Seiler to deny the existence of the giant cell, and to make the statement that cross-sections of blood and lymph vessels have been mistaken for it. Dr. Henry did not agree with him in this view, but thought that the irregular contour of the giant cell and its granular protoplasm were sufficiently characteristic. Additional evidence of the existence of this cell was furnished by the experiment of introducing beneath the skin of an animal two thin glass covers fastened together. In the interspace of the glasses giant cells had been found, and in such an experiment there could be no question of the cross-section of vessels. Dr. Seiler had several times referred to what was known here and elsewhere as Formad's theory of tuberculin, which is: That in certain animals predisposed to phthisis, and presumably in some human beings, the lymph spaces are abnormally small, or, in other words, that in a given area of tissue there is to be found a greater number of endothelial cells than in non-strumous animals. He did not think that this theory should be so extensively quoted until some more decided attempt had been made to establish or refute it. This might be readily done, he thought, by counting the cells in a given area of the tissue of strumous animals, and comparing their number with that contained in the same area of tissue of non-strumous animals. He did not think that any greater difficulty would be met with in this attempt than had been successfully encountered in the enumeration of the blood cells.

Dr. Bruen said that he believed in a hopeful prognosis in the early stages of many varieties of phthisis; even when the process of phthisis was advanced, the management of cases was more successful when the lesions were localized; less advanced lesions were more grave when they were widely disseminated. He thought that it had been proved that phthisis could be produced by inhalation of inorganic irritating particles, especially if there was inherited predisposition to phthisis or an artificially damaged constitution. Might not bacterial elements, he asked, be among the irritants capable of developing phthisis, when inspired in large numbers? And he thought they might be even more capable of doing damage than inorganic materials, because they possessed the power of proliferation. He agreed in the main with the views expressed by Dr. Seiler, and he considered the paper most instructive and interesting.

Dr. Miles thought it worth while to note the frequent occurrence of tuberculosis among those afflicted with chronic nervous and mental diseases. At the institutions for the feebleminded and insane, phthisis or tuberculosis was a common cause of death. This fact, he thought, would lend support to the views of Formad rather than to those of Koch.

Dr. J. T. Eskedon had observed that some who had participated in the discussion had referred to the views of the pathology of tuberculosis expressed by Dr. Seiler, and to those entertained by Dr. Formad, in order to prove the same thing. He regarded the theories of each of these gentlemen as widely different. If tuberculosis was the result of inflammation in a person whose lymph channels were abnormally narrow, as claimed by the latter, he could not see that phthisis differed from tuberculosis, as maintained by the former. In regard to tuberculosis being frequently developed in chronic diseases of the brain and cord, throwing light on the pathology of the former, he thought that the association of these diseases proved nothing more than that a prolonged period of lowered functions of the body was a favorable condition for the development of tuberculosis. He confessed that he did not know what to believe with reference to the pathology of tuberculosis; to his mind there had not been enough proved to firmly establish any theory yet advanced, so that it might be accepted as positive fact. He agreed with Dr. Shakespeare in demanding more pathological investigation following the clinical observation of the disease before he could accept as positive any view of the pathology of tuberculosis. He called attention to the fact that many of the best clinical observers of large experience, such as Flint, Da Costa, and Hughes Bennett, considered tuberculosis and phthisis to be identical.

Dr. Davis asked Dr. Seiler if he taught that tubercle was caused by a cancerous focus? to which Dr. Seiler replied in the affirmative. Dr. Davis said it was important to know whether this is the case or not, as the German surgeons excise cancerous glands, not so much for the deformity they produce as to obviate the liability to general infection, and he asked if Dr. Seiler would sanction this practice. As regards the possibility of cure, he believed, with Koster, Billroth, and Koenig, that tubercle...
was a local affection and not a general disease. He had seen tuberculosis as marked in the knee as in the lung, the military tubercles being within an eighth or a quarter of an inch each other. He had also seen tumor albus of the knee recover without operation. If tuberculosis of the knee can be recovered from, he believed the same might occur in tuberculosis of the lungs.

NEW YORK ACADEMY OF MEDICINE.

A stated meeting was held November 1, 1883, Fordyce Barker, M. D., LL. D., President, in the chair.

After the reading of the minutes of the previous meeting, Dr. J. G. Adams offered a written protest relating to that portion reserving certain resolutions adopted by the Academy in April last, which protest he wished to have entered on the minutes of the society.

It was voted to lay the protest upon the table.

Before introducing the regular business of the evening, the President made some complimentary remarks on the lately deceased members, Dr. Charles Wright and Dr. Frederick D. Lente, both of whom had been expected to read papers before the Academy the present winter.

Dr. T. H. Burchard then read a Memoir of the late Dr. Frederick D. Lente.—Dr. Burchard described his illustrious friend as most unpretentious and gentle, standing on the very mountain-top of mental vision, and from his exalted observation taking in a broad conception of life, with all its incidental duties and responsibilities. Extreme conscientiousness might well be predicated of him as a distinguishing characteristic; his honor was as dear to him as his life. He was indefatigable as a student; retiring late and rising early, he turned to profit the midnight hours. Mere physical fatigue was to him no excuse for mental inactivity. When his tired limbs refused to carry him, he was often found late at night or early in the morning bolstered up in bed, surrounded with books and periodicals, All that he did was done with rare thoroughness. Student as he was, his studies never led him into devions and idle speculations; his ideas were always practical. As a diagnostician, he was painstaking and exact. No desire for brilliant display ever led him into the hasty expression of an immature opinion. In the widest sense of the word, he was a good physician, skillful, devoted, self-sacrificing; indifferent to his own infirmities and oblivious to personal comfort, he brought to his patient's relief a strong brain, a ripe experience, and a tender heart.

On the Rapid Evacuation of Stone from the Bladder after Crushing; with the Presentation of a New and Simplified Evacuator.—Dr. F. N. Otis read a paper with this heading. He traced the history of the evacuator from the first one invented by Sir Philip Crampton down to the present time, describing that of Crampton and that of Clover in particular, referring to that of Mercier, and then, coming down to the present time, the important improvements in the vesical evacuator made by Dr. Bigelow, of Boston, and also by Sir Henry Thompson, of London, and Mr. Harrison, of Liverpool. A number of illustrations of the instrument, with its progressive modifications and improvements, were given. Regarding tolerance of the bladder to instrumental interference, Dr. Otis thought it had been established, by his own experience and that of others, long before it was first brought prominently forward by Dr. Bigelow as a fact of importance in successful litholapaxy. Dr. Bigelow had the mental acumen, the practical talent, and the courage to turn to use, in making this operation in the highest degree successful, the crude experience previously acquired by his fellow-surgeons in operations upon the genito-urinary tract. Dr. Otis believed that the principal reason of lack of success with Clover's instrument was the use of an evacuating tube too small in size; it was taught at that time that the normal circumference of the male urethra was only twenty-one millimetres. He, however, had shown that the normal urethra would admit an instrument varying from thirty-two up to forty and more millimetres in circumference, this variation also bearing a certain ratio to the circumference of the penis. To the size of the evacuating tube used, Dr. Otis attached the greatest importance in the ease and rapidity of removal of the fragments of stone. This fact was illustrated in removing crushed coral from a bottle with the same instrument and under like conditions, except that at one experiment a tube thirty millimetres in circumference was employed, and in another one of but twenty-seven millimetres, the amount of the crushed coral removed within thirty seconds at the former experiment being 300 grains, and at the second but 180 grains. Assuming, therefore, that the normal urethra was thirty-two millimetres in circumference, he believed that any contractions below this standard should be divided, and time be allowed for healing to take place before proceeding to litholapaxy. If, however, in an old subject the prostate were enlarged, he did not insist upon passing a large-sized evacuating tube, believing that the danger of doing so was greater than that attending the disadvantages pertaining to the smaller tube. If the urethra were not enlarged to its normal size in case contractions were present, either by previous division or dilatation, there was danger of Wounding the canal and producing hemorhage on the passage of a large-sized evacuating tube, and consequent difficulty of deciding whether damage had not been done the bladder; or, if a small-sized tube were employed, it must be attended by certain disadvantages.

It was particularly important that any constriction of the external meatus should be overcome by division with the knife. Dr. Bigelow recommended the use of a tube not below 24 nor above 31 millimetres in circumference; Dr. Otis had not, in the measurement of a large number of urethras, found one normally below 28 millimetres in circumference; if, therefore, the canal fell below this size, he did not hesitate to enlarge it, believing that the inability to pass a larger instrument was due to constriction. The only change made in the Bigelow evacuating tube was a greater curvature at the end, by which it was rendered easier of introduction, and less liable to become clogged with mucus.

After describing the evacuators invented by different surgeons, and those by Dr. Bigelow in particular, and stating that he had always found the last instrument perfected by Dr. Bigelow to work with entire satisfaction, he remarked that the cost was very considerable, and there was the objection also that the strainer was liable to become clogged with mucus and other material, and require to be cleaned. Dr. Otis then described a simple instrument recently invented by himself, which, besides possessing other virtues, was reasonably cheap, being sold for half the price demanded for that of Dr. Bigelow. It consisted of a glass globe, about two inches in diameter, into one side of which a metallic tube was introduced, extending upward, and connected without with a rubber air-chamber; into the other side another metallic tube was introduced, extending downward, and connected with the tube leading to the bladder; the particles of stone fell into a receptacle attached to the globe on its lower surface. The globe was filled with water by suction force through the end of the tube, or it was poured in directly at the junction with the debris-receiver; the amount of fluid in the bladder could also be increased by the latter method. If thought desirable in any given case, the quantity of water in the glass globe could be increased by filling the air-chamber with water. Pressing upon the rubber air-chamber, the water was forced into the bladder, and, on removing the pressure, it re-
turned loaded with particles of stone, which dropped directly into the receptacle below, and were not in the least disturbed by the agitation of the fluid above.

The paper being open for discussion, Dr. E. L. Keyes said that he had not seen the instrument presented by Dr. Otis before to-day, and had not had an opportunity to test it practically; but he was pleased with its great simplicity and apparent working; it was further evidence of the great amount of inventive ingenuity possessed by the author of the paper. He had always found Dr. Bigelow's instrument answer the purpose for which it was invented perfectly, but that invented by Dr. Otis, it would seem, would answer equally well; it was smaller, more easily portable, and cheaper. Before introducing the tube entirely into the bladder, it was of advantage to distend the canal by partially evacuating the reservoir of its contained fluid. He imagined that some damage might result from the introduction of air into the bladder and its mixture with the water, if the rubber ball were compressed too forcibly. Dr. Otis's instrument possessed the advantage that, being made of glass, the operator could see the degree of progress made. As to tolerance of the bladder, that was a fact known to the first inventors of instruments for its evacuation. It might be stated, also, that the inventions of Clover and others were intended only for use upon the unhealthy, not upon the healthy, bladder. Dr. Keyes did not believe that the most successful results in litholapaxy depended alone upon the large size of the evacuating tube, or any other single factor, but upon the best combination of all the factors and conditions concerned. Doubtless the larger the tube, consistent with the size of the urethra, the better, but the possible danger of introducing a large tube through the canal, whether with reason or not, was, it seemed, considered by the majority of surgeons a sufficient ground for the employment of a smaller-sized tube, notwithstanding the disadvantages of the latter. He himself did not think we should insist upon a rigid rule as to the size of the male urethra, and upon dividing or dilating the canal in all cases in which it did not correspond to our ideal.

The discussion was closed by Dr. Otis.

NEW YORK CLINICAL SOCIETY.

A regular meeting was held June 22, 1883, Dr. E. L. Partridge, Chairman.

The Treatment of Hydrocele.—Dr. Robert Arbe read a paper on this subject, which will be given in a future number of the journal.

Dr. R. J. Hall had injected carbolic acid in five or six cases. All his patients were cured. He thought less inflammation was excited by it than by iodine. The quantity injected was usually 3 ss. of the pure acid, never more than 3 j. In one case no re-accumulation of fluid took place. In view of the fact that a dangerous degree of inflammation was occasionally set up by iodine, he preferred very much the treatment by carbolic acid. He quoted Virchow as authority for the statement that old hydroceles with very thick walls were always incurable by any injection, as it was difficult for the two surfaces to come in contact and obliterate the sac; furthermore, these sacs were composed of old fibrous tissue, almost destitute of vessels, and hence reparative inflammation could not occur.

Dr. Arbe had seen some of these old cases cured by injecting iodine.

The Chairman thought that the pain produced depended more upon the nervous irritability of the patient than upon the condition of the membrane of the sac. He saw the patient who had died from the puncture. He was a very feeble old man, and probably would have died from any other slight cause.

Dr. Arbe said the pain produced was first local, then in the back, and from there it went to the pubes. He had once thought that the amount of pain depended on the thinness of the sac, but so many exceptions were found that he had concluded that no rule could be laid down in this respect. The largest amount of tincture of iodine used in any case was 3 j. Very great shock was produced in one case in which only 1 j. were used.

Dr. J. E. Winter said he had always given a hypodermic injection of morphine before injecting the iodine, and it had seemed to him that less pain and less inflammation occurred than when this was omitted. The quantity of tincture of iodine used by him was from 3 j to 3 j, and it was allowed to remain in the sac.

Dr. L. E. Holt had found tapping the hydrocele with a fine trocar and then scarifying the inside of the sac with the point of the instrument to be very satisfactory in children. He had used it in nearly thirty cases, and had never seen any bad results follow. The inflammation excited was usually very moderate, and a prompt cure was generally obtained.

Broncho-pneumonia with Delirium.—Dr. A. A. Smith reported a case of broncho-pneumonia accompanied with a remarkable degree of delirium. The patient, a man of twenty-four, had suffered from intermittent fever three years before, and, a few months prior to the present trouble, from an attack of dry pleurisy, from which he made a slow recovery. Pthisis was in the family on one side and gout on the other. About one month before, Dr. Smith had made out a spot of consolidation on the left side. About two weeks after this a pulmonary hemorrhage of half a pint occurred. The temperature ran up rapidly after this to 100° F., where it remained for four or five days in spite of the fact that sixty grains of quinine a day were given for two days. Four days after the quinine was stopped, active delirium set in, with complete insomnias; these lasting for seventy-two hours, the temperature remaining about 101° to 102° during this period. After a natural sleep of about three hours, the patient awoke with the mind perfectly clear. The delirium did not return. The next day a new spot of broncho-pneumonia was found on the left side and one on the right side. The temperature and pulse now fell to normal, and the pneumonia was clearing up. He had seen such delirium in lobar pneumonia, and it was especially likely to occur in pleuro-pneumonia, but he had never before seen it in broncho-pneumonia. It had seemed to him quite unlikely that the delirium was due to the quinine. The patient in previous diseases had not shown a particular predisposition to head symptoms.

Cystic Tumor of the Abdomen.—Dr. H. S. Norris read the following history:

The patient, a single man, aged twenty-seven, has always been very "rugged," and denies venereal. Has noticed, however, that for ten years his right side has been larger than the left. Was never sick in his life until one year ago, when in Pittsburgh, when he had an attack of cholera morbus which was followed by a prolonged inability to take solid food without pain and nausea. During this period, up to April, 1883, his weight fell from 180 to 159. There was no vomiting of blood during this time, and as long as he confined himself to milk he was free from abdominal symptoms. On the 26th of April, at Pittsburgh, he had a severe fall, some twenty feet, I believe, breaking two ribs on the right side. At that time there was some question in the mind of his physicians as to whether rupture of the liver had not occurred. He was confined to his bed for over four weeks, and returned to New York June 1st, when I saw him.

Patient is tall and thin, almost emaciated. Walks feebly, and with a cane; has no dyspncea, and has not had. There is
no cough. On stripping patient, I found chest-walls excessively thin and apparently sunken, but abdomen large, and very prominently so on the right side. Heart not displaced; no evidence of any trouble in thoracic cavity. The tumor on the right side is continuous with the liver, and extends to the level of the crest of the ilium below to the median line in front, and, as well as I could determine, nearly to the spine behind. This tumor has been increasing of late, my patient said. There was distinct fluctuation, and the diagnosis of fluid was readily made. I introduced a hypodermic needle, and, while it was in the tumor, noticed that the respiratory movements were conveyed to the needle. I drew off about half an ounce of the fluid, which I found to be clear serum; no bile. No signs of hydatids were found.

On June 8th I aspirated the tumor. I introduced the aspirating needle into the most prominent part of the tumor, the patient lying down, and drew off twelve ounces of a turbid red fluid, but could not get any more. Fluctuation was still evident in other parts of the tumor, though absent where my needle was, and it was less rounded at this point. I reintroduced the needle at the lowest point where fluctuation could be felt, which was about the anterior border of the quadratus lumborum, and drew off four ounces more of the same kind of fluid. Still fluctuation was very evident, but I did not deem it prudent to continue any farther at that time. A sharp reaction set in, with fever, rapid pulse, tympanitis, and, for a time, I feared general peritonitis, but, by the liberal use of morphin and poultries, escaped all serious trouble. The fluid removed was evidently bloody serum. It was turbid, reddish-brown, alkaline, e. g., 1012, did not coagulate spontaneously, presented no clots on standing, was loaded with albumin. In fact, in making Pettenkofer's test, it became almost solid on adding sulphuric acid. I regret to say that, after making the above tests, I overlooked the specimen entirely, so that it became decomposed and I threw it away.

On June 10th my patient called on me and reported himself better than he had been since bis fall. The size of the abdomen is very much reduced, but there is still a considerable swelling, with distinct fluctuation. I introduced the hypodermic needle again and drew off some perfectly clear serum, resembling in all respects that found at the first examination.

Dr. Abbe was inclined, from the history, to think that there had been localized peritonitis in which the inflammatory products had formed adhesions, and that, bound down by these, the exudation had become localized so as to resemble a cyst. It was astonishing how soon lymph was thrown out after injuries to the peritoneum. He recalled an autopsy on a child who had been run over by a wagon twelve hours before death. Here already the intestines were found matted together by the lymph which had been poured out.

Dr. Hall thought it well established that any cyst, after a time, might change its character. Thus, we did not always find bile in a cyst of the gall-bladder, nor the echinococcus in hydatid cysts; but the absence of these in the fluid drawn off was not to be taken as conclusive proof against those diseases.

Intussusception.—Dr. L. E. Holt presented a specimen taken from a child, two months and a half of age, who had died of intussusception after an illness of a little more than sixty hours. The child was only seen once during life. It was taken with vomiting one evening quite suddenly, the matter ejected being at first greenish, then of a very foul but not faeculent odor, and the vomiting continued up to the day of death. On the second day there were four mucous and bloody stools, but after that absolutely nothing passed the bowels. Tympanites now rapidly came on, with marked prostration. The child died in a convulsion. No abdominal tumor was made out during life.

The autopsy showed great abdominal distension from gas, but no peritonitis. The lower part of the large intestine was empty, and, following this up, there was found, a little to the right of the spine and lying close against it, in about the region of the hepatic flexure of the colon, a tumor about two inches long and one inch in width. It was tightly held down by the mesentery. The intestine appeared healthy, and was not even much congested. The tumor was hard and solid to the touch. An unsuccessful attempt was made to force water through it from both directions. A probe was passed without much difficulty through the whole tumor, entering a small slit-like opening which appeared at its lower extremity. No orifice corresponding to the vermiform appendix could be found. The intussusception was exceedingly tight. A traction force of several pounds was required for its reduction, and some of the longitudinal muscular bands gave way before this was completely accomplished. The intussusception began at the ileo-cecal valve; about two inches of the ileum passed through this into the cecum, this then passed into the colon, and the latter was intussuscepted into itself. The intussuscepted portion was composed of two inches of the ileum, the cecum, and six inches of the colon. The age of the child made the case of more than usual interest.

Of somewhat over ninety cases reported by Smith and West, only three of the patients were under three months of age, while nearly one half of them were between the ages of three and twelve months. The small size and somewhat unusual position of the tumor would have made the diagnosis difficult even before tympanities developed.

The Chairman remarked that he had seen often, in autopsies on very young infants, multiple intussusceptions, which were slight, easily reduced, and probably produced by the death throes, as they seemed to have nothing to do with the cause of death.

Reports on the Progress of Medicine.

OPHTHALMOLOGY.

BY CHARLES STEDMAN BULL, M. D.

LECTURE ON OPHTHALMOLOGY AND OTOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; DEDICATED TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO THE NURSERY AND CHILD'S HOSPITAL.

(Concluded from p. 423.)

XEROSIS OF THE CONJUNCTIVA AND CORNEA IN SMALL CHILDREN.—Leber ("Archiv für Ophthalmologie," xxix, 1) makes the following preliminary statement of the results of his observations upon this subject: 1. The epithelial scales of the desquamating conjunctiva are covered, sometimes completely, by peculiar fungi, partly in the shape of bacilli, partly in the shape of micrococci. The same fungi are to be found in the covering of the corneal ulcer, as well as inside the suppurating eyeballs. 2. Introduction of a quantity of the fungi cultivated upon gelatin into the conjunctival cul-de-sac of rabbits, without wounding the conjunctiva, caused a severe ulcerating lesion of the cornea, which lasted for some days and then healed. In the corneal parenchyma small stellate colonies of these fungi were found. 3. Defective nutrition could not be regarded as the cause in Leber's case, because the child showed no signs of it until after the appearance of the eye lesion. The plantation of the fungi could not be caused by a previous desiccation of the eye, for the closure of the lids was perfect, and they were kept closed from the beginning of the disease. 4. The child died of broncho-pneumonia, and at the autopsy the brain was found perfectly normal. In the pelvis of the kidneys there was a desquamative
epithelial lesion which strongly resembled the xerosis of the conjunctiva. The peculiar fungus was also present. There was no other change in the kidneys. It is probable that the change in the pelves of the kidneys was secondary to an excretory infection.

**Hydrocephalus with Inflammatory Atrophy of the Optic Nerve.**—Leber ("Archiv für Ophthalmologie," xxix, 1) reports a case of this nature in a young girl, aged fifteen and a half, and then reviews the five cases hitherto published. In these cases there was an almost exactly similar group of symptoms: a continuous flow of a watery fluid from the nose, in connection with long-continued severe brain symptoms, headache, epileptic attacks, vomiting, somnolence, attacks of unconsciousness, delirium, pronounced amblyopia, and blindness of both eyes from papillitis or its termination in atrophy of the optic nerve. In Leber's own case there was complete anosmia. In Nettleship's case there was partial anosmia, palpitation of the heart, and exophthalmus, and in Baxter's case there was hyper trophy of the thyroid gland. Leber thinks that the brain symptoms and blindness were due to hydrocephalus internus. An examination of the excreted fluid led him to regard it as cerebrospinal fluid. This generally flowed from the left nostril.

**Variations in the Diameter of the Sensible Image of a Luminous Point.**—Leroy ("Archiv für Ophthalmologie," May-June, 1883) gives here the principal factors upon which his theory rests, which he considers necessary in view of certain criticisms made upon his work by Charpentier. The first or physical factor is that the image of a point is always a certain surface, the illumination of which diminishes from center to periphery, where it tends to zero. The retinal surface on which this image rests has always a certain intensity, maxima in the direction of the regularly refracted rays, and sensibly constant in the limits of the image. The physiological factor is Aubert's law. He then formulates the following proposition: When the papillary diameter has a certain invariable value, and when the intensity of the luminous point observed is indefinitely diminished and even supposed to be placed in a space theoretically obscure, the diameter of the image sensibly diminishes and tends to zero. As a corollary to this, if a sufficiently small intensity is given to the luminous point, the diameter of its sensible image will be sensibly nil, no matter what the papillary diameter may be.

**The Effects of Strong Light upon the Eye.**—Little ("Ophthalmic Review," July, 1883) reports two cases showing the effect of strong light upon the eye. The first was the case of a gentleman whose right eye had been exposed suddenly and for a moment to a very strong electric light. He was blinded for several minutes, and he suffered from intolerance of light and severe headache for some days. He complained of a mist and dark specks before the right eye, with vision of 2/3. There was a distinct haziness over the optic disc and neighboring retina. The second case was of blepharospasm caused by lightning. A gentleman, aged fifty-six, while walking, was struck down by lightning, but was not rendered insensible. On rising, he found he could not open his eyes. Two days later Little saw him, and found marked blepharospasm in both eyes. He said his eyes were hot and painful. He remained in this condition for thirteen days, when he opened his eyes partially. He then steadily improved, and ultimately recovered with good vision and a normal fundus.

**The Trachomatous Process.**—Mandelstamm ("Archiv für Ophthalmologie," xxix, 1) has contributed an interesting article to the literature of trachoma. He formulates his reasons for declining to regard the disease as a specific one as follows: 1. There are no specific structures in trachoma, no "trachoma grains," which stamp the disease as specific. The structures which are called "trachoma grains" are follicles or groups of lymph-cells, which are met with also in simple edematous catarrh, in so-called "follicular catarrh"; in the catarrhal inflammations which accompany serofulose diseases of the cornea; in those which are produced by inflammation of the lachrymal sac; in traumatic conjunctivitis; and in that form of conjunctivitis produced by atropine. There is no pathological product present in trachoma which is not met with in other conjunctival diseases. What Sennich has called the "trachoma grain," and which is said always to lead to the formation of cicatrical tissue, is nothing but proliferation in a papilla, which may either disappear without a trace or may remain until cicatrization begins to develop in the conjunctiva. 2. Acute follicular catarrh and acute trachoma, according to the devotees of dualism, can not be distinguished from each other, either clinically or histologically. Although inflamed mucous membranes, in which follicles are present in great numbers, very often heal without a trace of proliferation, yet almost as many cases occur in which these follicles are replaced by hypertrophic papillae or overgrown by them, and in which affections of the cornea, opacities, and pannus are developed before our eyes. In some cases, in which the follicles were few in number and confined to the lower lid, while in the upper lid there was proliferation of the papille, cicatrices developed in the lower lid in consequence of the protracted inflammation. On the other hand, cases are frequently observed of the so-called "papillary trachoma" or "trachoma grains" with pannus, which disappear without leaving a trace behind of cicatrical proliferation, though there may be a greater vulnerability or tendency to relapses, such as is frequently met with in corneal affections. To the objection that cicatrices possibly exist even here which have escaped observation, we may answer, Where, then, is the proof that the so-called "follicular catarrh" does not leave scars behind which are only seen by microscopical examination, and are entirely hidden from macroscopical observation? If we regard trachoma as a simple inflammatory process, with acute or chronic course, then the cicatrical formation in trachoma loses its specific significance, just as does the epithelial proliferation which may or may not be met with. 3. The presence of microcosces in trachomatous conjunctiva is rather against the specific character of trachoma than in its favor; for as soon as the same microcosces is met with in blepharitis, and is found to excite an inflammation by inoculation, which clinically is like a follicular catarrh, then this same microcosce is in a position merely to cause an inflammation in the mucous membrane, without being accountable for the consequences. 4. No physician, no matter how many cases of trachoma he may have seen and treated, can affirm with any certainty what may result from an inflamed conjunctiva, where only follicles are visible; whether the disease runs an acute or a chronic course, with or without cicatrical formation. Therefore there is no clinical fact which will facilitate a differentiation of follicular catarrh from trachoma, even though the two may possess a histological identity.

**Visual Illusions.**—Mayerhausen ("Klin. Mon. für Augenheilkunde," July, 1883) begins his paper with Heuse's assertion in regard to the production of the illusion presented by Zöllner's test—that the appearance is so developed as if the inferior angle inclosed the succeeding one, and hence were larger; just as every inclosing body is greater than the body inclosed. Mayerhausen agrees with this idea, provided that the difference in size between the given and added figures does not overstep a fixed limit. We learn to consider the space lying between the figures which lie one within the other, in a certain sense, as the resultant figure by comparison; and this resultant figure, which in the one case surrounds the original figure, and in the other is inclosed within it, seems to be either entirely larger or entirely
space between the original figure. The paper is well illustrated
diagrams.

**Experimental Keratitis and Its Bearing upon Stricker's
Sciences," July, 1885) has been experimenting in inducing inflam-
mation in the cornea, and gives the following results of his
observations: He believes that Stricker is correct in claiming
that in silver-stained cornes, the mosaic tracings indicate the
outlines of pus-cells, but that he is wrong in his conclusions
as to their origin, and that he will continue to be mistaken so
long as he confines himself to a single staining (silver). He
limits his study to the eschar and its immediate vicinity, because
silver-stained specimens show changes in no other locality.
Minor claims to have established the immigration theory; be-
cause the pus-cells are similar in appearance to the white blood-
corpuscles, they can be traced from the corneal periphery to
the point of irritation; and, having also gained access to the
corneal tissue through the eschar, they are most abundant im-
mediately around this center, where dead but intact corneal
corpuscles may still be recognized. The corneal corpuscles
show signs of proliferation some time after the cell-immi-
gration has set in; and this proliferation gives rise, not
to pus-cells, but to new corneal corpuscles, and they are strict-
ly limited to the zone surrounding the dead corneal cor-
puscles, whereas leucocytes or pus-cells in abundance can be
found in various parts of the cornea, at a distance from this
point.

**Inflammation of the Retro-ocular Cellular Tissue.—**
Panas ("Archives d'ophtalmologie," May-June, 1885) goes into
the history of what is barbarously called "tenonitis," and then
gives his own views of the pathology of the disease. The first
symptom is intense circum-orbital pain, coming on in paroxysms;
the course followed by the lancinating pain is always localized
in the branches of the ophthalmic branch of the fifth nerve,
the supra-orbital and nasal. An especially characteristic symp-
tom is the extreme pain caused by any movement of the eyeball;
the patients, therefore, usually keep the eyelids closed and the
eyes immovable. On the second or third day, sometimes later,
when the circum-orbital and orbital pain has reached its height,
there appears a characteristic symptom in the chemosis or serum
oedema of the conjunctiva, around the cornea. It first
appears in the inferior cul-de-sac, and thence extends all round
the cornea. When the chemosis is very pronounced, the swollen
conjunctiva sometimes becomes reddened and inflamed. This
conjunctival phlegmasia is only fortuitous and secondary, and
may not occur throughout the entire course of the disease.
The pain caused by movements of the eyeball is explained by re-
membering that the inflammation of the retro-bulbar connective
tissue is propagated necessarily into the muscular sheaths, which
are themselves composed of loose cellular tissue in direct com-
unication with that of the capsule of the eyeball. The en-
gorgement and severe infiltration of the capsule of the globe
causes a certain degree of exophthalmas. An ophthalmoscopic
examination shows dilatation of the retinal veins, and sometimes
a venous pulse. There is nothing noticeable about the condition
of the pupil, which reacts both to light and to atropia; hence
we conclude that the motor ciliary nerves are not influenced by
the disease. The duration of the disease varies between two and
three weeks. It always terminates by resolution. Among the
constitutional causes are certain fevers, like scarlatina and
measles and mumps. Arthritic rheumatism, however, is the
principal cause. In the treatment, Panas recommends the salicy-
late of sodium, in doses of four to five grammes daily, and, when
the pain is severe, hypodermic injections of morphine. If the
chemosis is marked, he scarifies the conjunctiva and uses hot,
enrolling applications. He thinks that a pressure-bandage also
sids in the absorption of the chemosis and in the resolution of the
inflammatory process.

**A New Form of Eye-Bandage.—** Peschel ("Arch. f. Augen-
hilk," xii, 4) has invented a new variety of bandage for the
purpose of applying a continuous bath to the eye, hoping thus
to obtain as complete disinfection as possible. He has a sort of
rubber mask constructed, which can be applied water-tight to
the face below the eyes, against the temples, and over the nose,
by means of a flexible metallic bow or arch, and an air-bag
beneath it. This mask is open upward toward the forehead, and
in a sitting posture the patient can thus keep the eyes continu-
ally immersed. This makk-bandage is constructed of three
shapes: for the right eye, for the left eye, and for both eyes.
Since September, 1882, Peschel has employed the apparatus in
a great many cases, partly to destroy certain organisms already
present, and partly to prevent their introduction from without;
and the results have been most satisfactory.

**The Question of the Erythropsia of Aphakial Eyes.—**
Purtseher ("Centralblatt für praktische Augenheilkunde," June,
1883) reports a number of cases of erythropsia after operation
for cataract, occurring in his own practice and in that of several
of his colleagues. He mentions first two cases occurring in the
practice of Hirschberg, and then two occurring in his own prac-
tice, and also refers to one case reported by Hirscherg and one
reported by Dimmer. From an examination of these six cases he
concludes: 1. That this form of erythropsia cannot be an
optical phenomenon. Color-dispersion can not be regarded as
a cause, for objects themselves, and not alone their edges, appear
red. Hence only two theories are thinkable: Either the cause
must lie in cloudy media which admit the passage of red light,
or it must be sought in vitreous or retinal hemorrhages. Both
these theories are, however, inapplicable to Purtseher's cases,
because in none of them was there ever any diminution of the
visual acuity. No positive result was ever gained by an
ophthalmo-endoscopic examination. 2. That the appearance of
erythropsia in aphakial eyes is not connected with the existence
of a coloboma as such, and therefore can not be regarded as occur-
ing exclusively after an extraction by Graefe's method. 3.
That any attempt at explanation on the basis of color-contrasts
does not accord with the facts. 4. That Hirscherg's attempt at
explanation is based on physiological grounds. Hirscherg thinks
that the erythropsia of aphakial eyes is due to a fatigue of the
retina, which is most noticeable in the evening, and more so for
highly refrangible rays than for rays of slight refrangibility.
Aubert assumes that the sensibility for blue or green is lost
after wearing dark-blue or dark-green glasses for ten minutes,
but that sensibility for red lasts for several hours. It might be
assumed also that a very rapidly fatigued retina would lose the
sensibility for the more refrangible rays of diffuse light sooner
than the sensibility for the less refrangible red rays. It should
also be remembered that among pigment colors red is recog-
nized by a low grade of illumination when all other colors are
unrecognizable. If it is true that erythropsia is more apt to
occur by diminished illumination, the phenomenon would be
more likely to occur in closed rooms and in the evening. 4.
That the phenomenon of erythropsia in aphakial eyes is purely
subjective, and situated in the light-perceptive apparatus. It is
partly directly, partly indirectly, dependent upon nerve influ-
ence. We may assume with certainty that a retina which has
been protected for a long time from the effect of bright light by
a cataract would be in a condition of much greater irritability
after the removal of the cataract. But its disposition to fatigue
would be also so much the greater. Purtseher thinks that this
fatigue of the retina is by no means the only cause of this ery-
thyropsia, but that we must look also to the most varying nervous
influences for producing such a condition of fatigue.
at all improbable that an unusually bright light, falling through the pupils on opening the eyes after sleep, may complete the exhaustion of a retina already fatigued.

**Catarrhal Conjunctivitis with Conjunctival Arthritis.**

—Robert ("Revue d'ophtalm.," July, 1883) reports a number of cases of conjunctivitis followed by arthritic rheumatism in which the conjunctival disease was characterized by an edematous swelling and purplish color of the eyelids, muco-purulent secretion, intense redness of the palpebral and ocular conjunctiva with some chemosis, continual lachrymation, sharp, shooting pains, and photophobia. This conjunctivitis, after several days of treatment, seems to terminate favorably, but there soon appear signs of inflammation in one or more joints, which resemble strongly the blemorrhagic arthritis. Robert thinks that this is a complex catarrhal affection developed under the influence of special atmospheric conditions.

**Eye Complications and Visual Disturbances in Typhus Dorsalis.**—Schmeichel ("Arch. f. Augenheilk.," xii, 4) gives the following résumé of his observations upon this subject: 1. The atrophy of the optic nerve is marked by the sharply defined discolored disc with its peculiar condition of its vessels; by the at first rapid, afterward gradual, diminution of vision; by the concentric limitation of the visual field; by the characteristic condition of the color-sense. 2. The disturbances in the condition of the pupil consist in reflex and total immobility of the pupil, in the myosis which is fixed against atropine action, and in the dissimilarity of the pupils. 3. The paralyses of the ocular muscles appear gradually and disappear slowly; they seldom last through life; they may appear again after their complete disappearance; and they are never met with in any other lesion of the spinal cord.

**On the Nature of the Jequirity Ophthalmia.**—Sattler ("Kl. Mon. f. Augenheilk.," June, 1883) has gone very fully into the nature of the process set up in a trachomatis conjunctiva by an infusion of the jequirity bean. He used infusions of the same strength as Wecker employed, and found that there was a stage of incubation of about three hours between the application of the infusion and the appearance of the first subjective and objective symptoms. The symptoms at first increase slowly, then more rapidly to a considerable height, so that, within sixteen hours after a single copious application of a good infusion, all the signs of a severe conjunctivitis were present. From twelve to sixteen hours later, with never more than a single daily application, the process has reached its height, remains at this point for a day or two longer, and then begins to subside. The membrane is then more easily stripped off from the tarsal portion of the conjunctiva; but it is still very thick in the retro-tarsal folds, and very adherent to the parts. The secretion is abundant and purulent. On the fifth or sixth day the formation of a membrane upon the palpebral conjunctiva ceases; but a number of weeks elapse before all signs of redness, unevenness, and yellowish discoloration of the conjunctiva have disappeared. In some cases, at the height of the inflammatory process, superficial clouding and dullness of the cornea, with loss of epithelium, make their appearance; but, if the infusion is not applied more than once a day, these corneal symptoms do not lead to anything serious. The intensity and duration of the inflammation may be markedly increased by a number of applications, especially if they are made somewhat rapidly, one after the other. By shortening the period of maceration of the beans to from three to six hours, a less violent conjunctivitis is produced. Increased concentration of the infusion makes it more active; but not the slightest proportional relation exists between increased concentration and increased intensity of inflammation. The effect of the infusion diminishes visibly with age, and finally disappears entirely. A very marked diminution of its activity also occurs when the maceration takes place in a hatching-oven at a temperature of 22° to 25° C, while its preparation with ice water, and standing for twenty-four days in a refrigerator, makes no perceptible difference in its activity. The microscopic examination of the infusion *always* showed the unmistakable forms of schizo-myceetes, or yeast fungi, which must be classed as a bacillus, which existed in enormous numbers in the fluid. In the purulent secretion of the conjunctiva, as well as in the membranes stripped from the latter, the same bacilli were found, in the spore-bearing stage, but never in very considerable numbers. The secretion of the jequirity ophthalmia, when introduced repeatedly into the conjunctival sac of another eye, produced a conjunctivitis which resembled the original inflammation, but was very much less intense. Bacilli-bearing spores were more abundant in the infiltrated conjunctiva, as well as in the sub-conjunctival tissues of the retro-tarsal folds, which was enormously infiltrated with a fibrinous and cellular exudation. Sattler undertook to make the jequirity-infusion free from germs by boiling, but in this he did not entirely succeed. By adding to the infusion of jequirity a solution of bicloride of mercury of the strength of one part in 10,000, the infusion was sterilized so far as the production of bacilli was concerned; but its application caused an intense conjunctivitis, which could not possibly be due to the sublimate, which is constantly used in the same strength as a disinfectant. Hence, the cause of the ophthalmia must be sought in the jequirity. The bacilli were prevented by the sublimate solution from germinating, but they were not robbed of their irritating qualities. The question whether the power of the jequirity-infusion to produce a peculiar kind of conjunctivitis depends upon the presence of the germ of a distinct bacillus, Sattler regards as answered definitely in the affirmative. He then considers the question whether this bacillus, entirely separated from the original mother-liquor, still possesses the same pathogenetic properties, and this, after due experimental observation, he answers decidedly in the negative.

**The Clinical Use of Jequirity.**—Wecker ("Annales d'oeuil.," May, June, 1883) lays down three propositions as to the value of jequirity in opthalmic practice for consideration. 1. Lotions of an infusion of the grains of jequirity certainly give rise to a purulent ophthalmia of a croupous nature, the intensity of which may be regulated by the number of lotions and the strength of the solution employed. In cases of slightly developed granulations and slight pannus, he advises the use of frequent lotions (three daily for three or more days), with an infusion of two- or three-per-cent. strength. In cases of ulceration or infiltration of the cornea, a two-per-cent. solution should be used. If the granulations are very thick and chronic, and there is a high grade of pannus, he thinks it advisable to produce an active inflammation as rapidly as possible by employing a five-per-cent. solution two or three times a day. These lotions should not, however, be employed simultaneously on both eyes, because of the pain occasioned during four or five days, and because, owing to the extreme swelling and hardness of the lids as well as to the presence of masses of fibrin covering the entire extent of the conjunctiva and eyelid, the condition of the cornea cannot be recognized. With the strong solutions may be obtained a real, virulent inflammation, extending to the lymphatic glands, which is sufficient to kill certain animals and to cause a phlegmonous inflammation of the most serious nature. 2. The cornea runs no risk during the evolution of the jequirity ophthalmia, provided the number of the lotions be not too greatly increased, and do not succeed each other too rapidly, especially if the five-per-cent. solution be employed. Grave corneal complications have been observed when numerous lotions of the strong maceration have been employed within a
short space of time. These complications may be avoided by using a very limited number of lotions, and by waiting until each lotion has produced its maximum effect—that is, from sixteen to twenty-four hours—before applying a second lotion. 3. The jéquirité ophthalmica, without doubt, destroys the granulations very rapidly, if care is observed in the manner of making the applications.

JEQUIRITÉ IN ALGERIA.—Sédan ("Receuil d'ophtalmologique," June, 1883), in a short article upon the new remedy for certain forms of conjunctival granulations, takes occasion to differ from the very satisfactory reports hitherto published of the efficacy of jéquirité. He has sometimes met with good results, as perfect as those gained by other methods of treatment, and he admits that the proportion of failures from its use has been no greater than that from sulphate of copper, tannin, or lead. He has found great differences in the specimens of beans, and as great differences in the strength of the various macerations. In view of this certainty of inequality of composition, he thinks there is nothing surprising in the difference in results. In sixteen cases treated at Ceoha, in Algeria, three proved successful. Seven cases were benefited. In six others, the inflammation produced was either slight or nil—in all insufficient. Severe pain followed after the fifth lotion, one case was badly aggravated, and in one case a chronic keratitis became acute, and would probably end in a perforation.

A MODE OF ILLUMINATING THE PERIMETER.—Priestley Smith ("Ophtalmic Review," July, 1883) offers the following plan of illuminating the perimeter: Upon the glass chimney of an ophthalmoscopic lamp he hangs a light piece of tin, which embraces it half way round, and reflects the whole of the light backward upon the wall. The wall behind the lamp is papered white over an area of about four feet square, and this white surface, being strongly illuminated, throws forward a diffused light around the patient's head, which gives a fairly equal illumination over the whole of the visual field. All other light being excluded from the room, there is a background of darkness, against which the test object stands out clearly. The center of the white area on the wall corresponds in height with the patient's head. For ophthalmoscopic purposes, a black curtain hangs over the whitened area of the world; when the perimeter is to be used, this is drawn aside, and the screen, already described, is hung upon the chimney of the lamp.

THE PATHOGENESIS OF DETACHMENT OF THE RETINA.—Still- ling ("Archiv für Augenheilkunde," xii, 3) reports the case of a young blacksmith who had lost the sight of the right eye from a perforation of the ball by a fragment of iron. The eye was irritable, but the media were sufficiently transient for him to make out an extensive detachment of the retina. The eyeball was enucleated, and immediately examined by careful dissection under water. Stilling was convinced, after a careful examination, that in this case the detachment of the retina was not caused by the perforation or by the traction of individual bands of connective tissue, but rather in consequence of a condensation of the entire vitreous, which caused the irregular, relief-map-like appearance of its external surface, and exerted traction on the retina on all sides.

THE ADVANTAGES OF THE PLANE OPHTHALMOSCOPIC MIRROR IN RETINOSCOPY.—Story ("Ophtalmic Review," August, 1883) asserts that with a concave mirror retinoscopy can not be satisfactorily carried out at a greater distance from the patient than 1 mm. 20 cm., or theraboutes, so that all degrees of myopia less than D. 1 exhibit hypermetropic movements of the shadows. With a plane mirror, however, sufficient light can be obtained to examine through a fairly diluted pupil at 4·5 mm., or even further than that from the patient, so that, except in degrees of myopia below D. 0·25, myopic movement can be observed.

Myopia of less than D. 0·25 may be treated as emmetropia. When, then, with a plane mirror at a distance of 4·5 mm., we find the hypermetropic movement, we conclude that there is no myopia, and in estimating the amount of ametropia we have no additions or subtractions to make, but declare at once that the weakest concave glass which produces hypermetropic movement is the measure of the myopia, and the strongest convex glass which allows the same movement is the measure of the hypermetropia. When the plane mirror is used in retinoscopy, the motions observed happen to be the same as those of the disc and blood-vessels in the method of testing refraction by the use of the mirror alone—viz., in the same direction as the observer or the mirror moves, in hypermetropia, and in the opposite direction in myopia. This method, as has been also mentioned by Chiberty, certainly enables the observer to approximately determine the degree of myopia, if myopia be present, in a shorter time than it can be done by any other method. An approximate estimation of the amount of ametropia can also be made by noticing the rate of the movement, the degree of luminosity, and the curvature of the shadows on each side of the illuminated area. Story recapitulates the following points of advantage: 1. In using a plane mirror for retinoscopy, stand as far from the patient as the illumination admits, and with a large pupil this distance may be as great as 4·5 mm. 2. If at the distance of 4·5 mm. the light and shadows move in the same direction as the mirror, the case is one of hypermetropia or emmetropia. 3. If they move in the direction opposite to that of the mirror, the case is one of myopia. 4. The brighter and smaller the image of the light on the patient's retina, and the faster it moves, the nearer is the refraction to emmetropia. 5. In correcting, the weakest concave glass which produces a movement with the mirror is the measure of the myopia, and the strongest convex glass which still permits of this movement is the measure of the hypermetropia.

CORNEAL GANGRENE PRODUCED BY ISANITION.—Thalberg ("Arch. of Ophthalmology," xii, 2) observed most of his cases of corneal gangrene in sucklings. The corneal disease was generally bilateral, and was preceded by a more or less pronounced xerosis of the specular conjunctiva. The most frequent cause appeared to be malnutrition of the child, coinciding in time with anemia or fasting in its nursing mother. In some of the cases, however, the cause appeared to be a disease in the child only, such as enteritis or pneumonia. In a part of the cases, the occurrence of a slight xerosis of the conjunctiva, suddenly the entire surface of both corneas became dull and clouded, and broke down into a soft, yellow mass, the condition extending in a few days down to Descemet's membrane. In another class of cases there existed for some time a decided xerosis of the conjunctiva or of the cornea, while the clouding, softening, and disintegration began at the corneal margin, and only at certain places penetrated quickly the corneal substance. The necrosis here began by a uniform superficial clouding of both corneas, either simultaneously or one shortly after the other. Simultaneously with this superficial clouding, grayish-white spots appeared at the center or near the margin of the cornea, which soon assumed a yellow color, and began to break down into minute shreds of mortified tissue. From these points the destruction spread rapidly over the entire cornea. In other cases a milk-white stripe appeared, running across the cornea. The next day the tissue covered by this stripe turned yellow and began to break down, while the clouding of the other parts began to appear. In all the cases the corneal tissue was nearly completely destroyed within three or four days. The result was either phthisis bulbi or corneal staphyloma. Incipient gangrene of the cornea was several times observed in the Military Hospital as a consequence of severe constitutional diseases, such as
typhoid fever, scurvy, and profound diarrhea, following ulceration of the intestines. It appeared either upon one or both corneas, preceded by a dryness and superficial clouding, with or without noticeable xerosis of the conjunctiva. Thalberg found eserinine very useful in the treatment of this corneal gangrene. He used it in the form of a vaseline ointment in the proportion of 0.02 to 0.04. The vaseline soothed the unpleasant feeling of dryness, and caused a temporary disappearance of the xerosis.

The Pathology of Typhoid.—Tscherning ("Archiv für Ophthalmologie," xxix, 1) finds that excessive degrees of myopia—that is, greater than D. 9—are found much oftener in the lower classes than in the higher, and this is especially so among women. Near-work plays an important rôle in the causation of myopia of moderate degrees, but the higher degrees of myopia, D. 9 and over, are entirely independent of near-work as a cause. The problem of measuring the focal length of the refractive media and the axis of the eye in the living person still needs solution. The question whether the myopia depends upon an increased curvature of the lenticular surfaces is still unsettled, though our present knowledge seems to point to the contrary. The question of the accommodation still remains where Helmholtz left it. The assertion as to the significance of the iris in accommodation is not tenable, for both the theoretical view of the subject and the observations of von Graefe of a perfect accommodation with total acquired aniridia are wholly against it. Another circumstance which weakens the theory is that it takes no note of the peculiar structure of the ciliary muscle. A defect in our knowledge of the act of accommodation is the slight acquaintance we have with the innervation of the ciliary muscle. Tscherning divides typical myopia into the following three forms: 1. A form of myopia which depends upon an "accidental" dis-proportion between the focal length of the refractive media and the length of the axis of the eye. 2. A functional myopia, produced by near-work, but without any diseased condition of the eye. 3. A form of myopia which is a real disease, *aut genebris*, the nature of which must perhaps be sought for in an insidious chorioiditis.

Iodoform in Ophthalmic Therapeutics.—Vossius ("Ar- chiv für Ophthalmologie," xxi, 1) recommends iodoform in all ulcerative processes of the cornea, especially in ulcers of serpents. The earlier the case applies for treatment, the more rapid and favorable is the effect. Its use is not contra-indicated by any complications of the iris. He also advises its use as an antiseptic in all superficial and deep, accidental and artificial wounds of the conjunctiva and cornea, as well as in wounds of the sclera. He has but rarely noticed any evil effects from its use, and never any abscess of the conjunctiva; nor has he ever met with the ambyopia spoken of by Hirschberg, and attributed by the latter to the use of this drug.

Injuries of the Eye due to a Fall.—Vossius ("Klin. Mon. für Augenheilkunde," July, 1888) reports a case of this nature occurring in a lad of seventeen years, who fell a distance of one metre and struck upon the taborosities of both ischia, without loss of consciousness. No evil result was felt until the following morning on awaking, when he noticed a cloud before the right eye. On the third day this eye was entirely blind. On examination, there was no perception of light, the media were clear, and the fundus was normal. Nineteen days later the papilla became a little pale, and from this time on an atrophy of the disc slowly declared itself. Under the treatment of the artificial leech and hypodermic injections of pilocarpine, followed later by injections of strychnine, vision was restored to 2/35 eccentrically. About a month after the accident symptoms of paralysis in the left leg made their appearance, and shortly after in the left arm. This paresis reached its height on May 28th, but never amounted to entire loss of locomotion of either limb, and by November had entirely disappeared. The one-sided character of the atrophy and functional disturbance of the right eye appeared to point with certainty to a lesion of the optic nerve in front of the chiasm, while the normal appearance of the vessels of the fundus pointed to a location of the lesion behind the point of entrance of the central vessels. From the nature of the injury, a lesion of the optic nerve within the optic foramen, in consequence of a fracture of its bony walls, did not seem possible; and, moreover, after the fall, every symptom of a serious fracture at the base of the skull—such as loss of consciousness, headache, vomiting, vertigo, bleeding from nose, mouth, or ears, and subconjunctival haemorrhage—was absent. On the other hand, the diagnosis of a slight fracture of the base of the skull in the vicinity of the right optic foramen was strengthened by the long-postponed appearance of left hemiplegia, which, although it disappeared, resembled closely a cerebral paralysis, with lesion of the island of Reil on the right side. The amaurosis, which was at first complete, was probably due to a partial separation of continuity of the optic nerve and compression of the remaining nerve fibers by a haemorrhage around the trunk of the optic nerve or within its sheath. The partial restoration of function would necessarily follow absorption of the extravasation, while those fibers which had been lacerated or divided would not regain their functional power.

Neuralastic Asthenopia and so-called Anaesthesia Retinæ.—Wilbrand ("Archiv für Augenheilkunde," xii, 3) regards the so-called retinal anesthesia as the expression of neurasthenic troubles, and as an analogous link in the chain of equivalent nervous symptoms occurring in other organs. In discussing the subject, he considers first the conditions of increased irritability and hyperesthesia of other organs in comparison with analogous symptoms in the eyes accompanying them. The tendency to rapid fatigue is a marked symptom, which is occasionally accompanied by diminution or loss of the sense of smell, of the sense of hearing, and of the sense of sight. The latter is manifested in various ways, as follows: 1. A peculiar form of limitation of the field of vision; 2. rapid disappearance of the object of fixation; 3. diminution of the central acuteness of vision; 4. occasional cloudy vision and transient scotomata; 5. loss of fixation of optical after-images; 6. loss of persistence in reading and working; 7. fatigue in the eyes and eyelids. The loss of persistence in working is due to a more rapid fatigue of the entire optical nervous apparatus, as well as of ocular muscles, especially the internal recti. In almost all these patients there exists a more or less pronounced insufficiency of the internal recti muscles. The duration of the attacks of cloudy vision is usually but a few minutes, and they appear like a gray veil before the eyes, or like smoke in the atmosphere. The transient diplopia and the temporary ptosis are caused by these conditions of fatigue or paresis. The very frequent occurrence of clonic blepharospasm with retinal anesthesia is well known, and has frequently been mentioned. Wilbrand considers that the differential diagnosis between neurasthenic asthenopia and other serious pathological conditions, such as progressive atrophy of the optic nerve, glaucoma, and sympathetic ophthalmia, is comparatively easy, and presents no difficulties. These neurasthenic-asthenopic troubles, in general, seem to bring but little danger to the optic nervous apparatus, and hence the prognosis is to be regarded as favorable. The treatment must be both local and constitutional.

Night-Blindness from Micrasmatic Influences.—Zimmer- mann's cases ("Arch. of Ophthalm," xii, 2) were observed in a family of four children, who previously were all healthy. After taking a house in a low situation and close to a sewer, the father suddenly fell ill from typhoid fever, and the children were attacked by intermittent fever together with hemeralopia. The
ophthalmoscope showed no alteration of the fundus. The fever disappeared after administration of quinine, but the night-blindness persisted, despite all treatment, until the family had left the house and removed to a higher locality in a healthy part of the city. Then a rapid improvement was observed, and in two weeks the hemeraloplia entirely disappeared and did not return.

Surgery.

By Charles R. Kelsey, M. D.

Posterior Rhinoscopy.—Mr. W. J. Walsham (“Lancet,” July 28, 1889) describes the following easy method of posterior rhinoscopy: A piece of soft, red rubber tubing, about one eighth of an inch in diameter, is introduced into one nostril and pushed very gently along the floor of the nose till it presents just below the soft palate. It is then gently seized with a forceps, drawn out through the mouth, and loosely tied across the upper lip to the end protruding from the nose, the elastic tube being stretched just sufficiently to loop the soft palate upward and forward, and draw it well away from the posterior wall of the pharynx. The looping of the palate on one side is often sufficient, but a better view is obtained by passing a tube through the other nostril and looping up the soft palate of that side in the same way. The posterior nares and naso-pharynx can now be examined with the ordinary laryngeal mirror with great facility. The introduction of the tube causes hardly any annoyance to the patient. Care, however, should be taken in passing the tube to let it only just present below the soft palate, as, if it is pressed further, it may impinge upon the lower pharynx and produce a tickling sensation or a desire to vomit.

Excision of the Tongue.—Mr. G. E. Walker (“Liverpool Med.-Chir. Journal,” July, 1889) advocates the following method of excising the tongue: The lower lip being drawn upward with the left hand so as to put the skin under the jaw on the stretch, an incision is made along the edge of the bone from angle to angle, making a V-shaped flap with a rounded angle. This flap is then dissected back. A large-handled needle, armed with a loop of silk, is then thrust through the tissues, at the right end of the incision, into the mouth, appearing just in front of the anterior palatine arch. By this loop the bight of an écrauvel wire is drawn back through the hole. On the left side the same thing is repeated, then the tongue is well drawn forward, and the wire, connected with the écrauvel, rapidly tightened. The stump of the tongue should be secured to the jaw by a thread to prevent embarrassment in breathing. A knife is then thrust from below, just in front of the track of the needle, and with a saving motion all the tissues of the floor of the mouth are separated from the bone. The whole of the parts are thus thrown open to examination. A single suture joins the apex of the flap to the skin, and the sides are left open for drainage.

Spina Bifida Treated by Injection.—The following report, by Dr. N. Smith, of a case of spina bifida which had been cured by injection of iodine, is exceedingly interesting, proving, as it would seem to do, that an efficient closure of a deficiency in the vertebrae can be effected without encroachment on the spinal canal (“Lancet,” August 4, 1889): The child was born with a deficiency of the arches of the lowest lumbar and upper sacral vertebrae. The size of the tumor was in circumference at the base 5| in., from side to side over the tumor 5| in., from above downward 5 in. The tumor was fully distended, translucent, and presented an ulcerated surface in the center, secretory fluid. There was no appearance of large nerves in the sac. The tumor was punctured with a No. 3 trocar, low down upon one side, and two ounces of clear, straw-colored fluid were drawn off, until the tumor was diminished to half its original size. Forty minutes of Dr. Morton’s iodo-glycerin fluid were then injected, and the puncture was closed with collodion and plaster. The constitutional disturbance was severe for twenty-four hours, after which the tumor began to cicatrize, gradually shrivelled up, and became like a piece of rough packer leather. The operation was performed on the 5th of September, 1877, and in twenty-five days the tumor consisted only of rough thickened skin, which projected slightly beyond the surrounding surface. A part of the wall of the sac of about the size of a shaving remained apparently unaffected by the injection. In February, 1878, nearly six months after the operation, hydrocephalus made its appearance, and ran its course in two years, at the end of which time the child died.

Autopsy.—Externally, the remains of the tumor appeared as thickened and puckered skin, and resistant to the touch. At the center there was a small patch, less in size than a shaving, of thinner skin, beneath which could be felt a small cavity. Upon dissection, the remnant of the tumor was found to consist of very dense fibrous cicatricial tissue, in the form of fibers and bands passing in all directions, and closely united together. The deficiency in the wall of the spinal canal was blocked by this cicatricial material, but with difficulty a very small probe could be passed along a tortuous passage leading from the small cavity already referred to in the canal. The cicatricial tissue did not extend beyond the opening into the canal, but it formed a remarkably firm wall in place of the deficiency in the bone. No nerves could be discovered passing from the canal to the wall of the sac.

Lumbar Colotony.—The following case of lumbar colotomy, reported by Mr. C. Lamminan (“Lancet,” August 4, 1889), is important in so far as it helps to arrive at a conclusion regarding the value of the operation, which is as yet in its infancy. The patient, a woman, aged fifty-four, was in comparatively good health until seized rather suddenly with the usual signs of intestinal obstruction. The diagnosis presented all of the usual difficulties, there being no tumor to be felt either through the rectum or abdominal wall. An O’Beirne’s tube seemed also to pass its full length, though after the operation it was evident this could not have been the case, as the stricture in the sigmoid dextrum hardly admitted a probe. After the usual general treatment (purging) had failed to afford relief, an operation was decided upon in consultation with Mr. Bryant, but the patient could not be brought to consent to its performance till she had passed seventeen days without nourishment by the stomach, and was, in consequence, much reduced. The usual incision in the left lumbar region was made and the dissection carried down to the lumbar fascia. This being divided, a large quantity of subcoelic fat was discovered, through which the collapsed intestine was finally reached. The stricture was found just at the bottom of the incision. The intestine was opened just above the disease and fastened to the skin. A stout carbolized catgut ligature was placed around the bowel below the disease, and the cancer excised. The ends of the ligature were cut off and the lower end of the bowel was returned to the abdominal cavity. The patient rallied with difficulty from the operation, and died forty-eight hours after. The stricture proved to be stricture. There was no autopsy.

The author states that since its introduction the operation has only been performed on one or two occasions—probably referring to Mr. Bryant’s experience, who also advised and directed this operation. There are nine previous ones on record, this being the tenth; although the incisions have differed in nearly every case, some being in the median line, some in the
dian incision, and subsequently one parallel with the last rib and one inch and a half above the posterior part of the crest of the ilium. Of the ten cases, five have been immediately fatal from the operation itself, and five have ended in recovery. Of the patients in these latter cases, one died in seven months, one in ten months, one was alive two years later, and in the other two the length of life is not reported. In deciding upon the propriety of the operation in any particular case, it would seem advisable to consider how long a life the patient is apt to have if not operated upon. For example, it would hardly seem good surgery to subject a patient to an operation the mortality of which is fifty per cent, and then have him die of a recurrence in seven months, when he might have lived seven months without the operation. The amount of actual obstruction caused by the disease must in many cases decide the propriety of surgical interference.

**Miscellany.**

The American Medical College, of St. Louis, and the State Board of Health of West Virginia.—As bearing upon a matter which was made the subject of comment in our columns some months ago, we now publish the following documents:

**Preamble and Resolutions of the American Medical College.**—At a meeting of the Board of Trustees of the American Medical College, of St. Louis, on Saturday, August 25, 1883, the following preamble and resolutions were offered and unanimously adopted:

WHEREAS, J. W. Davis, of Charleston, W. Va., did, in the year 1881, represent to the Dean of the American Medical College, of St. Louis, Mo., that he, Davis, had previously attended thirteen months’ medical lectures in the Medical Department of the University of Virginia, upon which attendance he claimed the privileges and rights of a second-course student, and asked to be admitted to the graduating class upon the attendance of one session in the American Medical College; and

WHEREAS, The statements and papers submitted by said J. W. Davis were taken as sufficient evidence of the previous attendance claimed by said Davis, and J. W. Davis duly graduated by the American Medical College in 1881; and

WHEREAS, It now appears, from evidence furnished by the State Board of Health of West Virginia, and from the recent recitation of said J. W. Davis upon the subject, that the representations of said J. W. Davis, in 1881, to the effect that he had previously attended medical lectures in the Medical Department of the University of Virginia, were false, and that he had not attended medical lectures anywhere previous to his attendance at the American Medical College in 1881; and

WHEREAS, The State Board of Health of West Virginia, after granting said J. W. Davis a certificate upon the basis of the diploma from the American Medical College, did revoke said certificate on account of the manner in which said diploma was obtained (through the false representations of the said J. W. Davis); and

WHEREAS, On account of suspicions regarding the status of the American Medical College resulting from the graduation of said J. W. Davis, said State Board of Health of West Virginia do refuse to grant a certificate of registration to Millard F. Hamilton, of Manningtown, W. Va., upon a diploma from the American Medical College, issued in June, 1883; therefore

Resolved, That the diploma of the said J. W. Davis, issued in 1881, by the American Medical College of St. Louis, be and the same is hereby revoked; and that the Secretary of the American Medical College be instructed to notify, as far as possible, boards of health throughout the country of this action.

Resolved, That Millard F. Hamilton, of Manningtown, W. Va., be and is hereby requested and advised to appear before the State Board of Health of West Virginia for examination, it being understood that, if the said Millard F. Hamilton pass a satisfactory examination before said Board, he will be granted a certificate upon the basis of his diploma from the American Medical College.

JACOB S. MERRELL,

**Pres. Board Trustees Amer. Med. College.**

Aug. 25, 1883.

A. Merrell,

**Sec’y Board Trustees Amer. Med. College.**

STATE BOARD OF HEALTH OF WEST VIRGINIA,

Wheeling, Aug. 25, 1883.

Professor Geo. C. Fitz, M.D., Dean American Medical College, St. Louis.

My dear Sir: Your communication of the 25th inst., covering preamble and resolutions of the American Medical College, of St. Louis, has been received, and is satisfactory.

Accepting this action of the trustees as an earnest of their good faith and the promise of a strict compliance with the standard of requirements of the State Board of Health of West Virginia in the matter of medical education, diplomas of the American Medical College will hereafter be recognized by the said Board as a sufficient basis for registration in West Virginia.

It is proper, however, that this notice be given: The State Board of Health of West Virginia has resolved, and so ordered, that in all cases hereafter where a recognized medical college shall have been found guilty, under any pretext whatever, of departing from its published curriculum and declared standard of requirements for graduation, the college so offending, notwithstanding promises of future faithful adherence to its rules relating to attendance on lectures and conferring the degree of Doctor of Medicine, shall be put on probation in this: that its alumni who may apply for registration must answer satisfactorily, under oath, concerning actual attendance on lectures, and the manner in which they obtained their diplomas, before they, the said applicants and graduates, can be registered, or the college granting such degrees recognized in West Virginia.

Very respectfully,

JAMES E. REEVES, M. D.,

Secretary.

It will be seen that the college acted the part of wisdom in the matter, and that the West Virginia board met that action in a spirit that, while it gives evidence that there is no probability of its relaxing its vigilance, ought to go far to strengthen the reputation it has already made for impartiality and discretion.

TOMSEN'S DISEASE.—This singular affection, called by the name of the physician who first observed it in himself and his family, can at present, thanks to the investigations of Thomasen, Leyden, Seeligmuller, Westphal, etc., be considered as a distinct disease, whose nature, however, still remains to be found; for, until now, microscopical researches have given a negative result. According to Thomasen, it is of psychical
MISCELLANY.

nature; but Westphal considers it as a congenital disorder of the muscular tonicity, and Juncusel as a congenital muscular hypertrophy. The disease is essentially hereditary, and follows other abnormal nervous manifestations. All the cases were congenital. The chief symptom is a spasmodic stiffness of certain muscles, appearing at the beginning of a movement. After the muscles of the legs have been at rest for some time, and the patient tries to get up, he feels suddenly a stiffness in the articulations of the legs, which are fixed by a tetanic contraction. This same stiffness shows itself also after violent muscular exercise, after certain complex movements, dancing, etc.; or after an unexpected sensation: when the patient is running, for example, if his foot comes into contact with a stone, it becomes rigidly fixed, and the patient stumbles, sometimes before he is able to save himself with his hands. M. Greffier, in the "France médicale," insists upon the important fact that the contraction only comes on at the beginning of a movement. When, moreover, he may be held in a fixed position for a number of times, the contraction disappears. It may be observed, also, in muscles supplied by cranial nerves, as in those of the tongue, face, and orbit. According to Thomson, imagination and cold can produce the spasm, which disappears by a repetition of the movements. The sphincters are never implicated. The muscular hypertrophy may be absent; the muscular power, tendon-reflexes, sensibility of the skin, and electrical irritability of the muscles, are normal. It is, therefore, difficult to mistake this disease for locomotor ataxy or pseudo-hypertrophic paralysis; the latter is a true paralysis, and the former is characterized by permanent stiffness, abnormal excitability, excess of the patellar tendon-reflex, and, finally, by symptoms of spinal epilepsy.—British Med. Jour.

VARIATIONS OF THE URINARY CHLORIDES.—No one will deny that a more frequent examination of the constituents of the urine might lead to the acquisition of fresh knowledge. Even in our public clinical institutions the systematic estimation of the most important urinary constituent is not regularly carried out. A complete clinical account of the changes in the urine which attend the active stages of the rhachitic process would probably be attended with important additions to medical science. When, moreover, it may be held in a fixed position for a number of times, the contraction disappears. It may be observed, also, in muscles supplied by cranial nerves, as in those of the tongue, face, and orbit. According to Thomson, imagination and cold can produce the spasm, which disappears by a repetition of the movements. The sphincters are never implicated. The muscular hypertrophy may be absent; the muscular power, tendon-reflexes, sensibility of the skin, and electrical irritability of the muscles, are normal. It is, therefore, difficult to mistake this disease for locomotor ataxy or pseudo-hypertrophic paralysis; the latter is a true paralysis, and the former is characterized by permanent stiffness, abnormal excitability, excess of the patellar tendon-reflex, and, finally, by symptoms of spinal epilepsy.—British Med. Jour.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from October 27, 1833, to November 3, 1833.—McKee, James C., Major and Surgeon. Relieved from duty in the Department of California and assigned to duty as Medical Director Department of the Columbia. Par. 5, S.O. 249, A. G. O., October 31, 1833.—Pack, Charles E., Captain and Assistant Surgeon. Assigned to duty as Fort Custer, M. T. Par. 1, S. O. 187, Department of Dakota, October 25, 1883.

SOCIETY MEETINGS FOR THE COMING WEEK.—Monday, November 12th: New York Academy of Sciences (Section in Chemistry and Technology); New York Ophthalmological Society (private); New York Medical-Historical Society (private). Tuesday, November 13th: American Public Health Association (Dover—first day); New York Surgical Society; East River Medical Association (private); Medical Societies of the Counties of Rensselaer and Ulster, N. Y.; Medical Society of the County of Camden, N. J.; Newark Medical Association (private); Jersey City Pathological Society; Trenton Medical Association (private). Wednesday, November 14th: American Public Health Association (second day); New York Pathological Society; American Microscopical Society of the City of New York; Medical Society of the County of Cayuga, N. Y. Thursday, November 15th: American Public Health Association (third day); New York Academy of Medicine; Friday, November 16th: American Public Health Association (fourth day).
THE NEW YORK MEDICAL JOURNAL, NOVEMBER 17, 1883.

Lectures and Addresses.

A MEMORIAL OF FREDERICK D. LENTE, A.M., M.D.*
BY T. HERRING BURCHARD, M.D.,
NEW YORK.

Mr. President and Fellows of the Academy: So rapidly fly the hours that it is well to pause occasionally amid our haste and labors to note the changes that they bring.

This very evening a paper was to have been presented before this Academy by our esteemed associate, Dr. Frederick D. Lente.

It is my painful duty to announce that the appointment will not be kept. Again the remorseless sycythe has been at work, and under the shadows of the Highlands, amid the scenes of busy and eventful years, our honored friend is sleeping the immortal sleep.

In many particulars Dr. Lente's professional career was anomalous, as his character was remarkable.

What our specific duty is, in the equation of life, must, from the very nature of things, ever remain a varying quantity. Our estimate of our personal duty, however, depends largely, if not chiefly, upon our personal capabilities of estimating the specific work required of us. Working simply for the work's sake—to kill time—however laudable the work may be, is not our idea of the highest devotion to duty. Our highest idea of duty is the highest conception of duty of which one's mind is capable.

He who has always lived in the valleys and has never trod the mountain-tops can have but a meager appreciation of unfolding panoramas of sleeping lakes and nesting villages, and the broadening far-off prospect beyond the hills. As he ascends, though, from one altitude to another, and his vision takes in a wider survey, his conceptions of "the far off, unattained, and dim" become changed, and vague surmises now give place to actual knowledge. But, as we ascend, the horizon recedes; "hills peep o'er hills, and Alps o'er Alps arise," and so to those choice minds of highest attainment are given broader vistas and wider fields for the employment of noble and generous deeds. And ever, as these adventurous climbers ascend, their eyes are gladdened and their hearts are cheered with loftier aspirations. Humanity rolls, like a mighty ocean, at their feet, and, though cold its waters and unfathomable its mysteries, they press higher and higher to fire the beacon lights.

Dr. Lente, modest, unpretentious, gentle as he was, stood on the very mountain-top, and from his exalted observation took in a broad conception of life, with all its incidental duties and obligations. Extreme conscientiousness might well be predicated of him as his predominant characteristic. Never have I met the man whose regard for truth was so immutable. The keenest justice, even in most trivial matters, governed in all his dealings. Honor was dearer to him than life. His professional obligations to his patients, his sense of professional responsibility, he regarded as but second to his accountability to his God. Sensitive of the rights of others, as he was of his own integrity, neither intimidation nor reward could swerve him from his own high sense of right.

Slander and vituperation, ever venomous, ever foul, sink infinitely beneath contempt when incited by professional jealousy, bigotry, and pique. The vicious intolerance breathed against Dr. Lente at Saratoga, while it failed to seriously annoy him, did awaken his profound mortification that in his profession such narrow-mindedness and illiberality could be found.

Life with Dr. Lente meant work; to him it was full of achievable possibilities. Indefatigable as a student, retiring late and rising early, he turned to profit the midnight hours. Mere physical fatigue was no excuse with him for mental inactivity. So, when his tired limbs refused to carry him, often have I found him, late at night or in the early morning, bolstered in his bed, surrounded with his books and periodicals.

All that he did was done with rare thoroughness. Dismaying ostentations display, and depreciating superficiality, the purpose of his studies was to make himself the master of his subject. Access to his thoughts meant more than mere intellectual acquaintance. His mind was a living thesaurus of information, facts, and theories, gathered with great discrimination from the widest domains of science and the arts. And yet, student as he was, his studies never led him into devious and idle speculation. He was extremely practical in all he did. Physically delicate, but with powers of endurance that were phenomenal, with an energy that was untiring and a devotion to duty that was sublime, he brought to the practice of his profession a mind of richest and most varied acquisitions, an experience that was remarkable for its variety and scope, and a heart ever mellowed with kindliness and good cheer. As a diagnostician he was painstaking, thorough, and exact. Haphazard diagnosis he deplored, and no opportunity for brilliant display ever tempted him into the hasty expression of an immature opinion. As a therapeutist, his intimate acquaintance with drugs and his extensive studies in physiological medication made him, at once, skillful and distinguished. As a practitioner, his fertility of expedients is illustrated in numerous inventions, formula, and instruments in general professional use. In the widest sense of the word he was "the good physician"—skillful, devoted, self-sacrificing. Indifferent to his own infirmities, and oblivious of his personal comfort, he brought to his patient's relief a strong brain, a ripe experience, a tender heart. As a scholar, he was an active or honorary member of most of the leading societies. He was one of the founders and an early president of the American Academy of Medicine, and a frequent contributor to current popular or professional journalism. Whatever came from his pen commanded attention. His more important contributions were his papers on "The Treatment of Intermittent Fever by the Hypodermic Injec-

* Read before the New York Academy of Medicine, November 1, 1889.
tion of Quinine," "The Sedative Action of Calomel in Disease," "Intra-uterine Medication," etc.

Dr. Lente was born in Newbern, N. C., in 1823. He graduated from the University of North Carolina in 1845. He studied medicine in the office of our distinguished confrère, Professor Alfred C. Post, and graduated from the Medical Department of the New York University in '49. During the following two years he served as House Surgeon under Valentine Mott in the New York Hospital. In 1851, having been appointed Surgeon to the West Point Foundry, the Doctor removed to Cold Spring, where, in 1853, he married Mary, the accomplished daughter of William Kemble, Esq.

Mrs. Lente, one son and three daughters survive him.

Dr. Lente's professional career at Cold Spring was one of remarkable success. His reputation as consultant and surgeon reached literally from New York to Albany. So highly prized were the practical advantages of Dr. Lente's office that a popular question among New York and Bellevue Hospital men once was: "After leaving the hospital, is it Cold Spring or Europe?"

In 1870 the doctor received and accepted the appointment as professor of gynaecology in the Medical Department of the New York University and assistant surgeon to the Woman's Hospital. After a year's arduous service in the city, interrupted by numerous professional calls up the Hudson, he returned to his former home, where he continued in active practice until failing health compelled him to seek a more genial climate.

Relinquishing a lucrative practice, he betook himself to Palatka, Fla., for the winter, and to Saratoga for the summer months.

It was at the latter place, and after a season of unusual activity and fatigue, that he was taken ill with cerebrospinal meningitis. Fortunately he was able to return to his family at Cold Spring, where, on the 11th of October, in the sixtieth year of his age, he peacefully breathed his last.

And thus ends the record of a noble man. He dignified his manhood by his consistent Christian life, and to his profession he added luster and renown. What matters it to us how soon we follow, if we meet the final issue with as pure a life and as sublime a faith as did our illustrious friend?

SCARLATINAL RHEUMATISM.—In the course of some clinical remarks on scarlet fever, published in the "Lancet" for October 27th, Dr. Martin Oxley, of Liverpool, says: "Here I would say, with regard to the administration of salicylates, that I would not recommend them in this complication of scarlet fever, seeing that the joint affection is always very slight, both as regards swelling and pain, and that the skin and kidneys are both desquamating, and not in a fit condition to be called upon to do any extra work. I would rely more upon quinine and tincture of perchloride of iron in small doses, with the application of a blister over the heart where it is affected; or, if these are contra-indicated, carbonate of ammonia and chlorate of potash in small but frequent doses. In the treatment of scarlet fever our great care should be, as far as possible, to take every means to prevent the sequelae; in the majority of cases there is not much difficulty, if the patient is kept in bed until the body has desquamated, and in a warm room for at least a week afterward, also to give a moderate amount of food, avoiding meat, keeping to a simple diet of milk, eggs, fish, stale bread, with milk, tea, coffee, and cocoa as a beverage."

THE EMINENT DOMAIN OF SANITARY SCIENCE,

AND THE USEFULNESS OF STATE BOARDS OF HEALTH.

IN GUARDING THE PUBLIC WELFARE.*

BY JAMES E. REEVES, M. D.,
SECONDARY OF THE STATE BOARD OF HEALTH OF WEST VIRGINIA.

Mr. President: I propose a few inquiries into the truth of a proposition which I consider vitally important not only to the State, but to the general interest of every social institution. The proposition to which I allude may, with some convenience, perhaps, be expressed in the following terms:

Without obedience to the laws of health, it is impossible to secure the highest culture of the citizen—physical, moral, and intellectual—and perpetuate the prosperity, freedom, and glory of the State.

Should I succeed in establishing the truth of this proposition, the labor of sanitarians will be more justly appreciated, as well as the immense agency exerted by State boards of health amid the restless activity and excitement of the social and political elements of our advancing and complex civilization.

The principles of sanitary science are not of modern origin. Indeed, they are as old as the Mosaic code, and their incurring rewards and penalties have marked the life-history of all the nations that have covered the earth. In their scope, they are wide enough to embrace all humanity, and just as applicable to communities of to-day as they were to the Jewish race thousands of years ago.

It may be truly said that the business of sanitary science begins and ends with man; but language has no single or compound word which fully expresses its varied relations—its social forces and necessities to human life and human society. Its aim is the growth of an improved race—a healthy life—a useful life—a happy life—and as long a life as possible. Commencing with uto-gestation, it compasses birth, infancy, childhood, adolescence, puberty, adult life, maturity; thence along the delective to old age, and to death! Every influence of food and drinks, clothing, exercise, education, soil, and climate, comes within its purview. Good health, therefore, embraces value in the broadest sense of that term. On the individual it confers happiness, dignity, and a thousand advantages in the struggle of life. To the State it gives wealth, power, and freedom.

Public health ever goes hand in hand with true liberty, and is the companion of orderly habits and pure morals. During the fourteenth century, when vice and misrule in Europe had their greatest sway, and the beautiful fruits of civilization were trampled under foot by barbarian warriors; when acquisitions that had cost mankind ages of toil and millions of money were lost in the general wreck; when the night of ignorance was darkest, and human degradation

* Read before the American Public Health Association, at its annual meeting, held at Detroit, November 13 to 17, 1883.
sunk to the lowest depths—then hygiene was neglected, and plagues numerous and almost universal rested upon the people.

But this is only one of the many examples that could be adduced in proof that general health and longevity are inconsistent with ignorance and slavery. Greece, with the loss of her liberty and the ruin of her cities, has an altered climate, dating back, perhaps, from the years of the Peloponnesian War—more than four hundred years before the Christian era—when polished and populous Athens was devastated by fire and sword, and plagues followed in the train to complete the horrors of her lamentable desolation and downfall!

In London, about the middle of the sixteenth century, the population was estimated at half a million, and the average duration of life was only twenty-five years—eighty dying annually out of every thousand of the population. The streets were narrow, scarcely paved, and equalled the imperfectly constructed sewers as receptacles of all manner of abominable filth; the dwellings, principally of wood, were overcrowded, and no attention whatever was paid to their ventilation; water was scantily supplied; personal and domiciliary cleanliness were neither encouraged nor enforced; and the city was given up to licentiousness. Then, in 1665, London was visited by plague, and it is recorded that in one night three thousand persons perished from that terrible disease; and that up to 1679 the mortality from that source alone amounted to one hundred thousand! But now, with its improved sanitation, its stupendous sewers which have been recently completed at a cost of twenty millions of dollars, and its population increased to millions, how different the result! Instead of twenty-five years, the average duration of life is above thirty-seven years, and the rate of mortality, instead of fifty, is a fraction less than twenty-four in a thousand of the population.

Calcutta, built on a swamp on the east side of the Hoogly, and, at a few miles distance, surrounded by lakes which are supplied from overflows of the river, by a proper system of drainage of that part of the city inhabited by Europeans has become as healthy as any country of the same latitude on earth; while, on the contrary, Stockholm, built on small islands at the entrance of Lake Malar, with a mean annual temperature of 40° F., and possessing the requisite natural advantages, if properly guarded and improved, to make it one of the healthiest cities in Europe, is, because of gross disregard of sanitary laws—imperfect drainage and a bad supply of water to houses—one of the unhealthiest in that quarter of the globe, as shown by the death-rate.

Sanitary science, therefore, is a segment of political economy, and should receive encouragement by the State as a wealth-creating factor—riches, indeed, to the whole people far above that of any other earthly value.

It has become a classic saying that "public health is public wealth"; but who can estimate it rightly? Every case of sickness and the loss of every life from preventable disease is a tax upon the material wealth of the State and a great sorrow to the family. Count the number of deaths in a community for any given period, multiply it by thirteen—the estimated number of sick on hand for each death—and you have the average total of sick persons cared for at an expense much greater than would have been necessary for their support in health. In addition to this estimate, let us remember that at least one third of all the cases of sickness and of the deaths that occur are preventable; that this suffering and continuing tax on health and life are in direct antagonism to industry and the general prosperity; that the visitation of diseases falls heaviest always on the poor and most helpless classes of the community; and that the pressure of bad health and poverty, with their far-reaching ill effects upon the growing and reproductive parts of the population, tends to deterioration of the race.

In times of epidemic visitation, all these ill influences culminate in general distress of the people. Let Asiatic cholera come, striking the young and the old, withering the pride of manhood and the beauty of youth—in many sections marauding, in others obliterating the festivities and gayeties of life, robbing the social circle and the family group in the garments of grief, spreading the gloom and striking the panic of sudden death—then, for the time, possibly, the value of public health, as well as legal statutes to protect it, will be justly appreciated; for, besides the general affliction from sickness and death, the direct loss in money would probably equal in amount, during the time, the whole expenditures of the national Government.

Political economists have said the cash value of the life of an able-bodied, industrious man is sixteen hundred dollars, and that the average value of men, women, and adolescents of both sexes above twelve years of age, is one thousand dollars. Now, accepting this estimate as a fair and proper basis for calculation of the wealth stored up in the United States, we may have some conception of the real value of the earnings of the human machine.

Besides native wealth, our country is enriched annually from immigration. Every steamer that plows its way to our shores comes freighted with human souls to swell the population of this country and enlarge the profits of labor. No migration of men has occurred in the world at all similar to that which has been pouring itself upon the shores of the United States for the past five years. In a single week we have again and again received into the bosom of society numbers as great as a Gothic army possessed in its ranks, and passed them away without hurt and without terror. Week after week, again and again they come—each vessel bringing frequently a thousand souls, a number greater than was borne by a fleet of many ships in the days when Greece invaded Ilion, or Xerxes Greece.

The question of immigration is, therefore, one of grave importance to American statesmen. It involves political, moral, and social consequences of a magnitude too vast for common apprehension. Who shall assume to tell what precise result will follow in this country from the bringing together of races of men hitherto comparatively isolated? Or who shall say whether the intellectual and physical power of the Anglo-Saxon, the cool and industrious vigor of the Teuton, or the elasticity and fire of the Celt, shall be the controlling influence in the coming time? That the inferior must recede or disappear before the superior races is an inevitable result, sanctioned alike by reason, analogy, and the
indisputable records of history. Nature's leaves, wherever civilization and science have unfolded them, bear the plain evidences that such has been the eternal course of her wise, although sometimes inscrutable, laws.

Let us hope that from the fusion of all these different families and different bloods there shall spring a composite race of men far greater capacity than those who at present govern the nation—a race which shall have no jarring prejudices, and be animated by only the loftiest sentiments for the common welfare.

It is computed that by immigration our country is annually enriched fifty million dollars, and with net profits of labor amounting to sixty-five million dollars. The great Northwest is receiving the larger share of this wealth; but along with it there are some threatenings and dangers which well deserve wise attention. The immigrant brings with him not only his money, but also his habits of life and heredity. These may either be very good or very bad. If the former, then his citizenship is a substantial acquisition to the wealth of the State. If the latter, he is at once both a moral and physical leper, and of incalculable danger to society. Fortunately, however, thus far the assimilating and moral forces of our American institutions have been sufficiently active to absorb this immense immigrant mass and convert it into strength of the nation.

But notwithstanding the seeming capability of our institutions to swallow up, easily digest, and assimilate the stream of humanity which is constantly pouring into this country from the Old World, we must not shut our eyes against the manifest and increasing tendency of this commingling of moral and social habits to greater latitude and excesses than are to be found in either of the parent countries. In other words, the demand for labor of every character, its handsome rewards, and the plenty of money, are powerful temptations to influence a departure from simple and correct habits of life, with their almost never-failing accompaniment of good health.

The popularity of the milder alcoholic beverages—ale, beer, and wine—is directly due to the influence of our adopted fellow-citizens in all classes of society. I should be untrue to myself, to my position, to the medical profession, and to humanity, if I let this opportunity pass without sounding a note of warning against the intemperate use of alcoholic drinks, and to speak of their influence to debase the citizen and his progeny—physically, morally, and mentally—and deny him and them good health and longevity.

The connection between drunkenness and crime, and between drunkenness and poverty, is close and unvarying in its effect upon society. The remarkable increase of insanity in recent years may, in part, be traced to the prevalence of the intemperate use of intoxicating liquors. That wine, beer, and the stronger beverages, when taken in excess, all tend to derange the mental manifestations, is a fact too familiar to medical men to require of me argument to prove its truth. They act upon and disorder the brain more directly, perhaps, than any other organ; and, by habitual excess, may at last induce permanent impairment of the mental faculties.

In times of epidemic visitation—when pestilence is sweeping the country—the intemperate and the drunkard are the first to fall by its arrows of death; and the chances of recovery from any disease or injury whatever are infinitely less for the drunkard than for the sober man. Were man to live as he should do—enjoying every good gift and abusing none—he would (saving accidents) live to extreme old age without disease. But alas! how many such careful, prudent, temperate lives could there-to-day be found in this great country of ours, where a kind Providence has made it possible for us to enjoy every blessing the whole world can afford? The denounced by the prophet Isaiah—"Woe to the drunkards"—"Woe to them that are mighty to drink wine"—is not only in course of fulfillment every day with the drunkard, but the curse extends to his children yet unborn, even to the third and fourth generation, by inheritance of appetites which are far more constant and certain in their descent than patriarchy.

It has been asserted that at least seven tenths of all the crimes and poverty and calamity to the people of the United States spring from the abuse of personal liberty in the use of spiritual, vinous, and malt liquors; and, if the charge be true—either in whole or in part—it is a subject which should concern sanitarians. Vice needs every possible exposure and discouragement to prevent its seeds from growth, and the lesson should everywhere be taught that good health and long life can not dwell in association with a poisoned mind or an upbraiding conscience.

The public-school system of the United States is the great national laboratory for shaping, refining, and directing, on a progressively higher intellectual, moral, and social plane, the tendencies of American citizenship. In its plastic mold the children from immigrant families are freely mingled with native English-speaking youth, the lessons there taught and the manners prescribed and enforced are carried to the homes of the children in every class of society to cultivate and ennoble the aspirations of parents and guardians, and combat immoral and debasing influences which have crept into our civilization.

In the American public-school system, therefore, are centered the greatest trusts and brightest hopes for the future of the republic. It is the nursery of statesmen, philosophers, scientists, and patriots; and, being invested with such a high and mighty alliance of interests, it has become the peculiar care of sanitarians as the vineyard for the nurture and growth of a healthy race of men and women who shall lead the whole world in civilization. How important, then, that guardians, principals, and teachers in our common schools shall be thoroughly qualified, by special training in physiology * and hygiene, for the discharge of the high responsibilities with which they have been clothed by the community and the State!

If the opportunity of the school-room for the dissemination of the principles of sanitary science were properly appreciated and diligently improved by teachers, it would soon come to pass that all classes of the people would pay respect and render obedience to its laws. Physiology and hygiene should receive far more attention than is now usu-

* Dunglison's "School Physiology" is admirably suited for use in public schools, and is, probably, the best of its class.
ally given these studies. At present, in many schools, they are treated as if they belonged to the ornamental branches of education rather than the useful, and are taught by title instead of by direct practical examples gathered from the every-day life of school-children.

In country districts, school life has many more exposures to unhealthy influences than are suffered in towns and cities. For example, it is no uncommon experience for some of the children to walk two or three miles—sometimes double that distance—every day they attend school; and, when the weather is wet and the roads muddy, they are frequently compelled to enter their classes with cold feet and damp clothing, and remain in that chilly, uncomfortable condition until the period of recess arrives, or, may be, until their return home in the evening. In winter time, when the roads are icy and slippery, or when the ground is covered with snow, and travel on foot most disagreeable and fatiguing, those who have long distances to walk must hurry their footsteps to escape being tardy in their appearance at roll-call, and, when they enter their classes, are all aglow and perspiring. In that condition they take their seats, soon feel chilly, and are too sleepy and stupid to take interest in the lessons. At noon, when the hour for dinner arrives, they eat hurriedly the cold food contained in their little baskets and buckets, but not, usually, with as sharp appetite and good digestion as when they are at home. Immediately after dinner they engage too vigorously in all sorts of play—running, jumping, "chasing the fox," base-ball, and various other fatiguing and relaxing exercises—so that by the time of the call "to books!" they are as tired and indisposed to study as when they reached school in the morning. Then, after dismissal, in the evening they are again tired out by the walk home, and thus they are more or less exposed to unhealthy influences every day during the school term.

The management of country schools should provide special accommodations for the relief and comfort of children who come with damp clothing and wet feet. This can be easily accomplished in a well-appointed reception-room for each sex, where should be kept always on hand and ready for use a sufficient number of pairs of shoes and stockings of different sizes, also several warm wraps with which to clothe and warm the tenderest of the exposed pupils until their own shoes and stockings and other garments are dry enough to put on, and they are ready to enter their classes.

Parents who are able to do so should be encouraged to supply the school store-room with an extra suit of clothing for each child they send, and, no doubt, in every community there could be gathered enough subscriptions of that kind from humane, well-to-do persons and families to meet the wants and needs of the poorer children at school whose wardrobes are already too scantily supplied to afford them comfort and proper protection in cold weather. Nowadays, however, rubber shoes, "gossamer" circulars, and gum coats have become so cheap and common it would seem that even the poorest families should be able to provide such articles of protection for their children.

To perfect the system I have indicated for guarding the health of school-children, and at the same time to cultivate a spirit of benevolence, there should be appointed by the principal or teacher, at the beginning of each quarter, a special committee—to be known as the Health-Saving Service—composed of both boys and girls selected from the older and more advanced pupils, and charged with the responsible duty of watching every day after the welfare and comfort of those who need assistance, particularly the little ones. At the close of each week this committee should be required to make formal report of its labors to the teacher or principal, naming the pupils relieved and the particular service rendered in each case. Then, at the end of the school term, a handsome premium should be awarded to the pupil who has taken greatest interest in the work or performed the largest number of acts of assistance.

All examples of exposure of health during school life should be seized by teachers and made the texts of little lectures on the principles of personal, domiciliary, and public hygiene. They should point to the danger to health from wet and cold feet, too violent exercise, sitting on the ground or in draughts when the body is warm and perspiring, excessive indulgence in eating and drinking, insufficient or improper clothing, breathing a bad atmosphere in crowded classrooms—all these and every other like impropriety or transgression of the laws of health should be made as plain as simple language and apt illustration can portray them.

It should be impressed upon the attention of school-children that the diseases which kill them in greatest numbers have been classed by wise men as filth diseases; that small-pox is easily preventable by vaccination; that diphtheria, typhoid fever, yellow fever, cholera, and even pulmonary consumption, are preventable by cleanliness and correct habits of life; that there are farm-houses in all parts of the country, groups of houses in every community, whole villages, sections of towns, and districts in cities, where slovenliness and filth so much abound that sickness in some form is present at all seasons of the year; that filth does not only infect the atmosphere immediately surrounding its accumulation, but can and does transmit its germs afar; and thus it has again and again happened that whole families, with every apparent surrounding of cleanliness, comfort, and luxury, have sickened and died from infection received through the channel of some drain-inlet, or the medium of the common water-supply.

The more surely to fix the memory of these truths, the teacher should employ illustration on the blackboard to show dangerous proximity of the family residence, the stable and barn-yard, the pig-sty, the duck-pond, the privy-vault, and the kitchen sink-drain, to the water-supply in the well or cistern. He should also tell how the atmosphere in the house may become poisoned and breed disease from decaying vegetables stored in the cellar; how the milk-supply of the family may become contaminated with filth and dangerous to drink; how dwelling-houses, workshops, and factories should be constructed to be healthy to live in and occupy; and how necessary, for the maintenance of good health, that they breathe fresh air, drink pure water, and have plenty of well-cooked, wholesome food.

Besides examples drawn from village and country life, the teacher in the city school may show, by diagram on the blackboard, the system of sewerage usually adopted in towns
and cities; the importance of traps to prevent the inlet of deadly gases from the public sewers through the channel of the kitchen-sink waste-pipe, the soil-pipe of the water-closet, and the overflow-pipe of the bedroom stationary wash-stand; the great danger to health from imperfect ventilation of dwelling-houses, school-rooms, theatres, churches, and public halls; the manner of the water-supply; the danger from open cesspools; the necessity of guarding the public markets and green-groceries, to prevent the sale of tainted meats, stale vegetables, and decaying fruits; and not the least to be dreaded and shunned—public funerals from infectious and contagious diseases.

In the city there are also every-day opportunities to "point a moral" from drunkenness, and from police arrests for various offenses which disturb the peace and good order of society. Such examples should be used to show the penalties and hardships of vice in contrast with the honorable and lasting rewards of a temperate, virtuous life. To encourage morality and the growth of true manhood, the lives of good men in contrast with the character of bad men should be presented for study. For example, liberty-loving Lafayette should be contrasted with that "great bad man" Mirabeau, his fellow-countryman, who had a mind of the highest order, and eloquence the most commanding and impressive, but his commentary on national liberty was personal licentiousness. A look into American history and biography will find the experience of Jefferson in proof that habits of temperance win long life and good health. Then, in English history, it may be seen that Sheridan, with all his oratory and wit, became an outcast from society—a drunk-en, fallen man. And Savage and Burns and Byron—had they not neglected and scorned the plain precepts of temperance, morality would then have had less cause to disclaim the alliance of genius; nor would vice be so readily heard uttering the base maxim that stormy passions are the necessary accompaniments of lofty intellect.

The State has made abundant provision by statute law for the intellectual training of its youth. Why not, at least, equal concern for their physical culture and development—mens sana in corpore sano?

Lord Stanley declared that "sanitary studies belong to the patriot no less than to the philanthropist. Don't fancy," said he, "that the mischief done by disease spreading in the community is to be measured by the number of deaths which ensue—that is the least part of the result, as, in the battle, the killed bear but a small proportion to the wounded. It is not merely by the crowded hospitals, the frequent funerals, the destitution of families, or the increased pressure of the public burdens, that you may test the sufferings of a nation over which sickness has passed; the real and lasting injury lies in the deterioration of race, in the seeds of disease transmitted to future generations, in the degeneracy and decay which are never detected till the evil is irreparable."

Lord Beaconsfield also was an active patron of sanitary science, and uttered the sentiment that "the health of the people is the first care of statesmen." Indeed, its objects rank among the most important matters now discussed by the highest intellects and most humane hearts in every civil-ized country. No jurist questions the right and duty of government to make and enforce laws for the protection of the public health, to secure not only as long a life as nature can give, but likewise as healthy and happy a life as possible.

The State erects imposing and costly edifices for the detention and punishment of criminals, for the education and care of the blind and deaf, and for the treatment of the insane. To support such establishments, with all their necessary appointments, hundreds of thousands of dollars are annually paid out of the public treasury, and the burden of taxation for that purpose is constantly increasing. Why not enact statutes to diminish the factors which furnish such charges to the State?

The law is singularly inconsistent in its protection and punishments. If a man commit murder, he may either be hanged or sent to the State prison for life; but preventable disease—scarlet fever, diphtheria, typhoid fever, small-pox, and other death-dealing agencies—may stealthily enter the household, kill the family, and be innocently regarded as an act of Divine Providence!

The poor pilferer in a dwelling-house at midnight may be in a state of starvation at the time he lays a trembling finger on something to eat in the larder, or on a silver waiter on the side-board, but, notwithstanding the pressure and desolation of hunger, if discovered in his trespass and theft, he is sent to prison and his family disgraced thereby; while the architect, the plumber, and, alike, the ignorant doctor, may enter in broad daylight—aye, even by call—and steal and destroy the life and health of the occupants.

The law makes common carriers responsible, regardless of accident, for damage done either to person or property; yet an American citizen may refuse the protection which vaccination affords against small-pox, carry that loathsome disease into a community, and start an epidemic.

If a pitfall be left in the street or public highway, and the citizen, his horse, or his ox, fall into it and is injured in any manner thereby, he may sue in a court of justice and recover from the town, city, or county, as the case may be, a sufficient sum of money to compensate for the damage sustained: but the same citizen may sicken and disable his own family, also the family of his neighbor, by accumulations of filth on his premises, and escape all legal responsibility.

Again, municipal ordinance says that, in order to avoid injury to persons and property, a locomotive engine and train of cars shall not exceed a speed of six miles an hour within the corporate limits; yet the same authority of law permits open cesspools, filthy streets and alleys, a contaminated water-supply to families, and the constant breeding of infectious and contagious diseases to kill the people.

And, again, to prevent litigation and strife among her citizens, the State has even gone so far as to prescribe the very words to be used in the purchase or transfer of property by "Richard Roe" or "John Doe." Why not the same particularity and care to prevent the rise and spread of sickness among the people?

Influenced by progressive minds in the medical profession, twenty-nine States have established State boards of health, and it is surely within the bounds of truth to affirm
that thereby thousands of valuable lives have been saved, also hundreds of thousands of dollars to the wealth of the States.

The American Public Health Association, backed as it is by the influence and support of the whole medical profession of the United States, is recognized as the great central agency for the dissemination of sanitary knowledge among the masses. Through its systematic efforts and wise administration of voluntary powers, a large public sentiment has already been secured in favor of health legislation; and, accordingly, it has been so done by legislators in many of the States.

I charge you, my brethren, to concentrate your energies and influence. Speak out as one man in the name of the dearest interest of God's children who look to you—and not unavailingly—for succor in time of their distress. If the medical profession will but remain true to itself—true alike to science and humanity—the time is not far distant when its exalted influence will compel obedience of legislators to public sentiment, and cover every State with statute law for the protection of the public health. Moral suasion may do much to encourage respect for sanitary science, but it requires the strong arm of statute law, with its severe penalties for violation, to enforce obedience to its precepts.

The West Virginia statute provides that "the State Board of Health shall take cognizance of the interests of the life and health of the inhabitants of the State, and shall make, or cause to be made, sanitary investigations and inquiries respecting the causes of diseases and the means of prevention." How broad the charge! and how humane and God-like the service which defends men, women, and children from preventable diseases! This is precisely the service which a State board of health may afford—the education of the people respecting the economic and political importance of public health; to exterminate and prevent pestilential diseases, and thus largely contribute to the general welfare.

During the last decade there has been most gratifying activity in the cultivation and diffusion of sanitary knowledge; and it is an encouraging sign of the times that so much attention is now being given by legislators to the prevention of disease as a duty of the State. The proud lead of the great Northwest States in the cultivation of sanitary science has awakened a general interest in the subject in all parts of our common country. All praise, therefore, to the industrious leaders in sanitary work in Illinois, Michigan, Wisconsin, and Minnesota. Little West Virginia, nestled in the mountains, and looking into the near future for the coming time when her inexhaustible stores of native wealth shall be unlocked to hundreds of thousands of busy laborers, has proudly acknowledged allegiance to the goddess Hygeia, under whose health-inspiring banner she has already won substantial victories and benefits for the saving of her citizens. But, while flushed with the stimulus of her triumphs, she turns in sadness, and with outstretched arms and pleading voice, to her elder sisters, by whom she is immediately surrounded—Ohio, Pennsylvania, Maryland, and the dear old Mother State—and says to them: "How long, oh! how long shall the land which the Lord thy God giveth thee be the Paradise of Quacks?"

West Virginia is very proud of that feature of her State Board of Health law regulating the practice of medicine and surgery. Nothing, I am sure, could work more smoothly and consistently with the interest of the public health than its execution as a part of the duties of the board; and I commend the example of its success to those States that have not yet taken the advanced step to secure higher medical education. This provision of the law strikes at none but those wholly incompetent to assume and discharge the sacred trust of a physician. Neither does it attack any so-called school in medicine; and the law is most reasonable and just, both to the medical profession and the general public.

From time to time laws are passed to regulate the sale of intoxicating liquors and the dispensing of poisons; to suppress lotteries and gambling-houses; to prevent the carrying of concealed weapons; to restrain the sharper, the swindler, the robber, and the assassin. Why not, with like propriety, pass laws to restrain the ignorant, and the pretender in medical practice who strikes at both life and purse, who can kill and then invoke the power of the courts to enforce payment for his murderous service? And is it not a ridiculous contradiction to say that a street nuisance which is prejudicial to the public health shall be abated by the power of law, and then with the next breath say that any man, without due qualification as a physician, may call himself doctor and kill his neighbor?

A lawyer, whose practice and mistakes can only affect the purse and property of his client, must undergo examination by learned judges before he can be admitted to the bar. To become a teacher in the common schools, one must pass an examination and receive a certificate of qualification before he or she can be employed. A pilot on a steamboat, before he can be admitted to the wheel, must learn every crook and bar in the channel—must know the stream so well that he can steer his craft, frightened with human life, as safely in the dark as in the light of day. But such is the inconsistency of law—such the commentary upon unlicensed personal liberty—that in many of the States any man calling himself doctor may swing his shingle, and, without the least restraint, prey upon the lives and property of his fellow-citizens.

The depreciated value of an American medical diploma is a reproach to the profession; and it is, therefore, high time that the conferring of degrees should be entirely divested from the department of instruction in medical colleges. This opinion is fully warranted by my own experience as a medical examiner. Not long ago a young gentleman—a graduate of a medical college in "good standing"—came to me for registration, and, to my utter astonishment, he could not answer the question, "What is sanitary science?" Another graduate in medicine, when asked, "What is semiology?" answered, "A description of the spermatozoa."

But the most shameful exhibit, involving the character of a medical college in "good standing," that has come to my knowledge is shown in the following correspondence:

My dear Sir: A friend writes me that you propose attending medical lectures. I write to present the claims of ---,
the medical center of the South and West—the healthiest large
city in America—beyond the reach of yellow fever, etc.
Good boarding, costing elsewhere twenty to twenty-five dol-
lars, can be had here for twelve to fifteen dollars per month.
Owing to our railroad fare is only half rate. No
school has better facilities for medical teaching than the
Medical College. As I am allowed a certain number of bene-
cficiaries from your State (West Virginia), I will take you as one
and charge you only fifty dollars instead of eighty dollars. With
this reduction, cheapness of board, and reduced railroad fare,
you can attend one of the best schools for less money than an
inferior one. Let me hear from you. Send names of other
students.
Yours truly,

This letter was a tablet copy—probably one of a hun-
dred of the same kind sent out to catch the unwary. It
came addressed (by mistake, of course) to a Wheeling phy-
sician who had already honorably finished his college course,
and from him it came into my hands, as a medical college
curiosity! It is without date, but its caption is freely illus-
trated with the name and picture of the college, and con-
tains the names of the faculty, trustees, and “demonstra-
tors.” In order to sound the depth to which “Demonstra-
tor” might be willing to descend in fishing for students,
regardless of quality (!), a veritable medical student sent him the following letter of inquiry, with orthography
and syntax specially set for the occasion:

Wheeling, W. Va., Aug. 18, '85.

Doct—

One of my friends who is trying to be a Doctor has got a let-
ter from you which says your College is one of the Best Col-
leges for Medical Teaching in America and that the fees are
cheaper than some other good Colleges and that saves my cir-
cumstance for I am a very poor young man and no matter how
much I may know of Theor of Medicine I can't practice in W. Va. without a Diploma from a good College like the one
you have in —— you offered to take my friend for $50 dollars
and you will do a poor young man a favor if you will take me
at the same rate for I have that much money I can pay you
in cash as soon as I get there. My friend will come with me and we
shall stay together at the same boarding house the report is here
that the yellow fever is in —— but I am not afraid of any dis-
ease for I have had the Small Pox very bad. Tell me what
books I will have to study at your College and when me and
my friend must come We come by —— I have gone through
with gray anatomy and the Electric dispensary and medituro
please tell me how long I will have to stay and when I can get
my Diploma and if I have to pay extra for it

In haste Yours Respectful

And here is the prompt reply that was sent to this
Wheeling student, showing that the style of his English
composition was no bar to admission at — Medical Col-
lege:

Mr.,

My dear Sir: Your favor of the 18th to hand. I have
one more special beneficiary to allow; so I will take you on
the same terms as I offered your friend. Am anxious that your
State should have a better representation in — than it has
had in the past. The other information you ask is contained in
the catalogue I mail herewith. If you begin your medical
course this fall, you can graduate Feb., 1885. That is as soon
as any respectable school can graduate you, unless you have
already taken a course. There is no place where you can learn
more medicine for the same amount of money than in —

I came here in '77 with a very light pocketbook to study med-
cine, and, contrary to my expectations, I had a little left after
graduating, and was given no beneficary privilege either.

The cushioned seats for our new amphitheatre have arrived
from the factory. They are all numbered, so that students on
matriculation reserve their seats for the ensuing session, those
matriculating first having choice. If you desire a seat near the
front, you had better remit me the matriculation fee ($5), leav-
ing the balance of $45, and I will matriculate you, select the
best seat possible, and mail you your matriculation ticket and
number of seat, so when you arrive you will not be crowded
back so far that you will be unable to see well the demonstra-
tions and experiments.

Hoping to hear from you in a few days, I am,

Yours truly,

This exhibit shows the prostitution of medical college
work to base purposes at “the medical center of the South
and West.” I have made the blanks to hide the identity of
the actors in the comedy, because this college has accepted
my friend Rauch’s “Minimum Requirements” for a medi-
cal college to be held in “good standing”; and, no doubt,
it's faculty are ready to swear by the West Virginia schedule
of requirements also! So much for mere promises of re-
form and a higher standard!

Finally, in exerting my efforts in advocacy of the cause
of sanitary progress, I should commit a serious blunder if I
neglected to bespeak the assistance and co-operation of the
ladies. Woman gave Massachusetts the first State Board of
Health in the United States, and from that beginning—
in 1869—twenty-eight States have followed the example.
There is yet much work for her to do, and none can do it
so well as she; and no cause possesses a stronger claim
upon her sympathies and affections. As science advances,
she gradually acquires her true position in the scale of
social life. Of the world’s inhabitants, 750,000,000 univer-
sally hold woman in a state of bondage and degradation;
250,000,000 alone allow her to approach her proper sphere
by acknowledging the marriage contract, paying deference
to her influence, and promoting her intellectual culture.
How much had the mind of man to be cultivated before it
could give expression to that sweet sentiment of Campbell?

“And say, without our hopes, without our fears,
Without the home which plighted love endeared,
Without the smile from partial beauty won,
Oh! what were man! a world without a sun.”

THE TREATMENT OF MIGRAINE.

By WILLIAM A. HAMMOND, M. D.,
SURGEON-GENERAL, U. S. ARMY (RETIRED); PROFESSOR OF DISEASES
OF THE MIND AND NERVOUS SYSTEM IN THE NEW YORK POST-GRADUATE
MEDICAL SCHOOL.

Unless we have clear ideas relative to the morbid pro-
cesses giving rise to the condition known as migraine, we

...
But, mainly through the investigations of Eulenburg, Du Bois-Reymond, and others, we have obtained very definite views in regard to the essential nature of migraine—a hemicrania, or sick headache—and the methods of treatment deduced therefrom are probably as exact as they are in any other disease, and likely to be followed by as beneficial results. Occasionally a case resists all treatment, but, as a rule, as soon as we have ascertained the kind of migraine we have to deal with, and have put into operation the proper remedial measures, success ensues.

Two distinct types of the disease have been differentiated: the angio-spastic and the angio-paralytic.

1. The angio-spastic—spasmodic or sympathico-tonic form of hemicrania—is the result of a spasm of the blood-vessels by which their caliber is diminished, and from which a state of anemia of the parts of the encephalon to which these vessels are distributed is produced. It is characterized, in addition to the pain, nausea and vomiting, noises in the ear, circles or flashes of light in the eyes, and mental and physical prostration, by certain oculo-pupillary and vaso-motor disturbances, which are generally easy of recognition. These are as follows:

During the paroxysm it is sometimes observed that the pupil on the affected side is dilated, while the eyelid is apparently sunk deeper in its socket than in the normal condition. The face and ear of the side on which the pain exists are pale and cold to the touch, and the temporal artery is contracted, so as to give, when compressed, the sensation of a tight cord. If the bulb of a thermometer be placed in the external auditory canal, it will be found that the temperature is about 0.5° F. below that of the unaffected side. Whatever tends to diminish the flow of blood to the painful region increases the intensity of the symptoms, while, on the other hand, whatever increases the quantity of intracranial blood lessens the pain and the severity of the other phenomena. Thus, if pressure be made on the common carotid of the side corresponding to that of the disease, the symptoms are increased in violence, while pressure on the opposite carotid, by causing a diversion of blood through the other artery, diminishes the suffering.

As the paroxysm passes off, and the pain becomes less, the pupil contracts, the vessels of the face become distended, the temperature rises a little above the normal standard, the conjunctiva is injected, the secretion of tears is augmented, and the pulse is accelerated. At the same time there are generally profuse perspiration and an increase in the amount of urine excreted. Ophthalmoscopic examination of the fundus of the eye shows that the choroid is paler than it is in the natural condition, and that the retinal vessels are smaller than they are in health.

2. The other form, which is called paralytic from the fact that the coats of the arteries are relaxed, and hence the caliber of the vessels increased, presents phenomena in many respects the very opposite of those which are characteristic of the first-named variety. During the existence of the paroxysm the pupil is contracted, as is also the opening of the eyelids. The face and ear of the affected side are red, and feel hot, and there is an absolute increase of temperature. The thermometer, the bulb of which is inserted into the external meatus, shows an increase of from 0.2° to 0.5° F. over that of the sound side. The temporal artery is enlarged and tortuous, and beats with increased force; compression of the carotid on the side corresponding to that of the disease lessens the pain, and whatever tends to increase the amount of intracranial blood intensifies all the symptoms. The fundus of the eye is, as Mollendorf observed, of a bright scarlet color.

Sometimes these conditions alternate, one paroxysm being of the spasmodic variety, and another presenting all the phenomena of the paralytic type. Occasionally both may exist at the same time on the opposite sides. At other times the oculo-pupillary and vaso-motor symptoms are absent, the pain alone being present. In such cases experiment only can determine the nature of the existing seizure.

Such being the pathology of migraine, the principles of treatment are clear and specific. In general terms, the indications are, in the spasmodic form, to relax the spasm of the vessels and to augment the quantity of intracranial blood; in the paralytic form, the treatment should be directed to increasing the tone of the arterial coats, thus lessening the flow of blood to the brain.

In the angio-spastic type, galvanism is of great service in the treatment of the paroxysm. One pole should be applied over the sympathetic nerve in the neck and the other over the solar plexus, and the current from about fifteen cells allowed to pass for two or three minutes. Often a single session will break up the seizure. There are, however, other means of still greater efficacy and availability.

I usually administer at first a hypodermic injection of about a quarter of a grain of morphine. Then I give, every fifteen minutes, a pill containing a drop of a one-per-cent. solution of nitro-glycerin, or a drop of the one-per-cent. solution on a lump of sugar. If the differential diagnosis has been correctly made, this plan will cut short nearly every paroxysm in which it is used, and in which there are no specific aetiological complications. If, for instance, the cause is malaria, a large dose of the sulphate of quinine should be given instead of the morphine. Half a drachm will not be too much in ordinary cases.

In the intervals between the paroxysms, nitro-glycerin, or glonoin, as it is often called, should be given steadily for several months, a drop of the one-per-cent. solution being taken three times a day. In addition, the bromide of sodium, or some other of the bromides, should be persistently administered during the same period. Their influence is antagonistic to all kinds of spasm, and hence they tend to prevent that condition in the vascular coats.

In the angio-paralytic form of migraine, galvanism, applied as in the form just considered, is often equally efficacious in cutting short a paroxysm. Cold to the nape of the neck is also useful, and compression of the carotid artery of the affected side with Dr. Corning's instrument sometimes acts like a charm. Internally, thirty or forty grains of guaiacum will often cut short a seizure, as will also ten grains of caffeine, or even strong coffee or tea.

Better still is a large dose—a hundred grains—of the bromide of sodium. This rarely fails to abort a paroxysm.
The bromides not only relax vaso-motor spasms, but they give tone to vessels the coats of which are relaxed.

In the intervals between the paroxysms the treatment should consist of the bromides, ergot, and strychnine. In those cases in which the symptoms other than the pain are not so decided as to admit of an exact diagnosis being made—and they are not uncommon—the treatment must be experimental. Often, however, indications for the therapies can be obtained by pressure being made on the carotid artery of the affected side. If the case be one of the spasmodic type, the pain will be increased by this procedure; if it is of the paralytic form, the pain will be diminished.

In both forms the stomach and bowels must be kept in good condition. Sometimes attacks of either kind are caused by undigested food in the stomach or intestines, and an emetic or a purgative aborts it at once.

NOTE UPON THE TREATMENT OF MIGRAINE.
BY ALLAN McLANE HAMILTON, M.D.

Migraine must be considered as much of a vascular as a nervous disease. It often, I may say generally, is found among those persons who have a predisposition to nervous and mental diseases, and whose strain springs from a phthisical or insane source. It exists as a dyscrasia, which may be called epileptic, and the attacks of headache, when repeated, are often the forerunners of convulsion and insanity—which develop in later years. I have deemed this relation of so much importance that I have for some time past questioned all epileptics in regard to the possibility of a history of early headaches.

In the treatment of migraine the following indications are presented: 1. The improvement of the general health and the removal of the cause. 2. The maintenance of a constant vascular balance. 3. The relief of the paroxysm. A consideration of the first division needs scarcely any special mention. The hypophosphites, the cod-liver oil and egg emulsion, and citrate of iron and ammonium, are indicated in various cases. For the maintenance of an even state of vascular tonus, I use digitalis or digitalin, and have known many discouraging cases to be freed from their headaches for some time, even for years. Of course, some care must be exercised in regulating the dose of this powerful drug, for a vascular hyperemia is to be avoided. Nitroglycerin, which I originally recommended for the anemic form of migraine several years ago, may be substituted for the digitalis, in half-minim doses of the ten-per-cent. solution, or the Tr. convallaris majalis may be given.

For the relief of the paroxysm itself, I find the administration of large repeated doses of ammonia, in the form of the carbonate, muriate, or aromatic spirits, to do most good. Twenty grains of the muriate of ammonia, well diluted, and given in Vichy water every hour until three or four doses are taken, will usually break up an attack. When we have reason to believe that the congestive stage of the attack is that needing our attention, we may give large doses of the bromide of ammonium in combination with the tincture of cannabis indica. If the attacks of migraine appear during or just after the menstrual period, the use of the bromide and cannabis mixture will be found to be attended with great benefit. When there is any periodicity in the occurrence of the headaches, and they have a certain regularity in expression, we are warranted in using the bromides as we would in epilepsy.

NOTE ON THE TREATMENT OF MIGRAINE.
BY ALFRED L. CARROLL, M.D.,
NEW BRIGHTON, N. Y.

Like other neuralgias, migraine may be induced by various causes, and its successful treatment depends upon the recognition and removal, if possible, of its source. No fixed therapeutic rules, therefore, can be laid down for its management, nor will any “favorite prescription” of a never-so- eminent physician prove uniformly efficacious. Some cases, for example, may be speedily and permanently relieved by properly selected eye-glasses after the signal failure of galvanism and caffeine, while others will yield to gynaecological agencies alone. I remember an instance in which migraine manifestly had its origin in the irritation induced by a dead tooth, setting up first a facial neuralgia, which subsequently gave place to periodical hemiancia with its attendant gastric disturbance. Again, we sometimes treat with cases which are seemingly due to chronic material toxemia, and which yield to arsenic, iron, and quinine. Anaemia, hyperemia, vaso-motor spasm, and angio-paralysis have been added as causes of migraine, and obviously, under such differing circumstances, a corresponding discrimination would have to be exercised between chalybeates, bromides, amyl nitrite, glonoin, and strychnine. As regards the large class of cases which, in the absence of any knowledge about them, we conveniently call idiopathic, our treatment must for the present consist of tentative empiricism, and from this point of view I have found more good results from the long-continued use of cannabis indica in small doses (one third to one half a grain of the extract) than from any other single remedy. Guarana, if taken early enough, will often palliate, or even cut short, an attack, but I have never seen permanent benefit from its employment; nor has my experience with any of the many vaunted cures encouraged me to believe that we are near the discovery of an unfailing specific.

Correspondence.

LETTER FROM ST. LOUIS.

The Missouri State Board of Health.—The St. Louis Gymnasium.—Discipline in the St. Louis Medical Society.—Medical and Sanitary Officers of the City.

St. Louis, November 7, 1882.

Dear Sir:—Hear hopes have been had that our Missouri Board of Health would be a credit to the profession here, as that of our neigh-

[End of document]
boring State has been; but, if a rumor which I heard the other day be true, there is ground for fear that we are doomed to disappointment. It was stated to me that a country physician applied to the Board of Health, at its recent session in this city, for registration. His diploma was issued by a medical school which the Board of Health has declined to recognize. He then presented a certificate of attendance at the College of Practitioners in this city, and was admitted to registration. The College of Practitioners does not grant diplomas, and the courses of lectures are only five weeks long. Now, on what ground the Board of Health could accept the certificate of attendance at a course of lectures of five weeks' duration in an institution which only proposes to give special demonstrative instruction to medical graduates and grants no diplomas at all, I can not see.

I once heard the late Dr. Hodgen say that the St. Louis gymnasium had supplied him with a number of very interesting surgical cases. The ease we were then discussing was one in which a robust, athletic young man had fallen while exercising on the horizontal bar and fractured one or two of the cervical vertebrae. I am reminded of this by seeing an account of the reopening of the gymnasium, which is said to be now one of the finest and most completely fitted establishments in the country. The organization was effected some twenty-six years ago. It has had its seasons of prosperity and of comparative failure, but now seems to be in a more prosperous condition than ever before. It has nearly seven hundred members enrolled, and owns the handsome property at present occupied. The main hall measures 102 by 60 feet. They have all the various forms of apparatus which have been found serviceable in developing and cultivating the physical powers. No doubt many of our young men will make good use of the opportunity afforded, by membership in the gymnasium association, to develop their muscles and secure more robust health, while it is probable that some, by immoderate exertion, or carelessness, or lack of skill in executing some difficult feat, will receive serious, perhaps fatal, injury.

There has been music in the air in the hall of the St. Louis Medical Society. Some of its members seem to have been impressed with the idea that a society which had so generally advertised its adherence to the Code of Ethics of the American Medical Association, as this society did last summer, ought to see to it that its own skirts were clear. Accordingly, a special committee of three members was appointed to take into consideration the ground for certain rumors with reference to the professional conduct and character of one or more members of the society, with instructions that, if these rumors proved to be well founded, they should formulate charges and prefer them before the Standing Committee on Ethics. As the result of these investigations, the committee were convinced that the rumors referred to were well founded. They formulated charges, cited the physician to appear before the Committee on Ethics, and presented before the committee evidence that they regarded the charges and specifications proved, with one exception, viz.: the charge of being guilty of criminal abortion. With regard to this charge the Committee on Ethics reported that while they were convinced of its truth they did not feel that the evidence was such as to constitute legal proof. As a result of the report of the Committee on Ethics, a motion was made and carried by which the physician referred to was expelled from the society. Early in the following week the person expelled brought suit against the three gentlemen who constituted the Investigating and Prosecuting Committee, for damages to the amount of $50,000, for malicious libel, inasmuch as they had procured his expulsion from the Medical Society and allowed the same to be published in the public prints. The original petition charged them with malicious libel on five counts, being the five charges preferred before the society. 1. Charging him with practicing criminal abortion. 2. With unprofessionally soliciting the patronage of another physician's patient, the other three charges being for unprofessional conduct and general bad reputation. He considered that his fair reputation and business prospects had been damaged to the amount of $10,000 on each one of these counts. When notice was served by the defendants to take depositions, the plaintiff withdrew all the counts but the first, thus reducing the amount of damages claimed from $50,000 to $10,000. It will be noticed that the count on which the claim is now made refers to the charge which the Committee on Ethics decided was not proved by the evidence adduced. It is by no means an easy matter to prove a man guilty of practicing abortion, as those who are aware of the crime are almost always {participes criminae}. It is to be hoped, however, that in this ease the truth will be demonstrated, and that, if this man be of such evil character as has been charged, he may receive the righteous retribution which his crime merits, in addition to the expulsion from the society. The Circuit Attorney testified yesterday before a notary that the plaintiff was indicted on the charge of having procured an abortion in the month of May, 1882, but that the indictment was not prosecuted because several important witnesses had been spirited away, secreted or in some manner prevented from appearing at court on the day of trial. The attorney expressed the belief that the plaintiff had directly and indirectly furnished money to important witnesses living elsewhere, to keep away from the city.

At the next meeting following that at which the vote of expulsion above referred to was passed, the same committee preferred charges against three other members of the medical society for unprofessional advertising and issuing of circulars. No final action has been taken in this case. In fact, the Committee on Ethics is put in rather a peculiar position with regard to this, inasmuch as an advertisement of "radical treatment of consumption" has been kept standing in the advertising columns of the daily papers by a physician who is himself one of the Committee on Ethics.

For the last six months the Mayor and the Council have been at loggerheads, and the municipal appointments which should have been made in April have just now been made and confirmed. In the reorganization of the Health Department some changes have been made. The new Health Commissioner is a man who has performed creditably to himself and satisfactorily to all concerned the duties that devolved upon him as assessor and collector of water-rates, and will undoubtedly be an efficient executive, though it does seem rather unsatisfactory that the head of the Health Department should be a non-medical man. The medical members of the Board of Health are Dr. Joseph Spiegelhalter, who has filled that position for a number of years, and Dr. E. M. Nelson, the editor of the "St. Louis Courier of Medicine," and a new man in political matters. The superintendent of the City Hospital is Dr. D. V. Dean, who has occupied that position for eight or nine years. The superintendent of the Female Hospital is Dr. G. F. Hubert, a young man who has been there for a few months only, having been appointed to the position on the resignation of Dr. P. V. Sehenek, who left it a year ago.

Dr. C. W. Stevens, who has just been appointed to take charge of the Insane Asylum, is a man of many years' practice, having had much previous experience in the charge of the State and county insane asylums.

The spread of disease by soiled linen carried in the street cars is one of the dangers to public health against which our sanitary officials have to proceed vigorously at times. The practice is prohibited by the sanitary code, and the Health Department is about to enforce the ordinance strictly, it is stated, punishing conductors if necessary.

D. APPLETON & CO. Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, NOV. 17, 1883.

PHYSICIANS AND SANITATION.

In an article with this title, the "Sanitary News," of Chicago, a publication which we hold in high esteem, seems to show itself somewhat nettled by the intimate connection that the medical profession conceives should exist between sanitary regulations proper and enactments for regulating the practice of medicine. "To the physician," says our contemporary, "no progress has been made in public health unless a law is secured which will regulate the practice of medicine, and prevent quacks from practising upon the credulity of people."

The adoption of any great measure to promote the public welfare is commonly secured by the united efforts of men whose individual sentiments as to matters of detail are somewhat diverse. When these measures are complex in their nature, it almost always happens that one of their features seems of supreme importance to one set of their supporters, and another to another. A great number of people may agree that a certain course of action is desirable, while scarcely any two of them may be moved by precisely the same reasons. Short of the millennium, human nature will no doubt continue so constituted as to keep up this state of things. We may allow, then, that physicians are apt to look upon the legal regulation of medical practice as high in the scale of means to be taken for protecting the public health. It is doubtless quite as true that sanitary engineers regard material sanitary appliances as by all odds the leading factor in sanitation. The hygienist who takes a broad survey of the whole field would perhaps consider the one class of men equally narrow-minded with the other; but, if he were a man acquainted with human nature, he would not stop to find fault with the fact, but would accept it as a necessary evil.

It may be that there is a tendency on the part of some physicians to view the suppression of quackery as the prime object to be accomplished by boards of health, but we know of none who would go so far as to assert that no progress had been made in public health legislation until a law for the purpose had been secured. That the matter is really one of very great importance, probably the engineers themselves would not deny, although the "Sanitary News" rates it as less important than either correct plumbing, ventilation, water-supply, or sewerage. How much warrant there is for considering the proper regulation of medical practice as at least of equal consequence with the several elements thus set ahead of it by our contemporary, may be gathered from Dr. Reeves's fervid words, in the paper read by him before the American Public Health Association this week, and published elsewhere in this issue of the journal. At all events, whatever may be the relative urgency of the measures held dearest by different sets of men, the end for which they all profess to be working is scarcely to be furthered by their falling foal of each other. An ill-natured taunt may easily give rise to an amount of dissension capable of neutralizing the product of years of concerted effort.

In further depreciation of the purely medical element in public sanitation, the "Sanitary News" goes on to say: "The aim of sanitary science is to place all people beyond the necessity of calling on a physician, be he good or bad. Sanitary science, if it is allowed perfection, will deprive medicinal administrators of their calling." The tribute conveyed in these self-evident propositions is so substantial that we can well afford to smile at any slur that may have been intended in the use of the epithet "medical administrators"—unless, indeed, those to whom it is applied are considered too stupid even to see that their efforts to promote sanitary legislation must, to some degree at least, ultimately prove subversive of their own material interests.

THE NEW YORK INFANT ASYLUM.

The management of the country branch of the asylum, we regret to say, still remains a matter of controversy, and it is difficult to form a satisfactory estimate of the merits of the case. A coroner's jury has found the resident physician incompetent and criminally negligent, besides which, it charges her with having returned a false certificate of death in the case of the child alleged to have been poisoned with ammonia. The newspapers have spoken of the probability of a warrant being issued by the coroner for her arrest on the charge of manslaughter. Under this stress of troubles, she has asked to be relieved from duty for the time being. A coroner's jury is not the loftiest sort of tribunal, and we fancy the public will attach no great weight to the finding in this instance, especially when it is borne in mind how easy it is in general to make a show of evidence against the administration of a hospital. We heartily trust that the lady will be able to make good her promise to clear herself of the charges pressed against her.

In another particular, matters seem more favorable for the managers than at the time of our last issue. It looked then as if a number of the medical officers were disposed to throw up their connection with the institution in disgust. We are now authorized by one of them, Dr. Paul F. Mundé, to state that his resignation, which, at his request, we announced last week, had nothing to do with the institution's present troubles. On the contrary, he assures us that it was handed in last spring, and kept in abeyance by request. He adds that his sympathy has been most heartily with the present medical board.

We have received from the secretary of the board of managers, Mr. Richard B. Kimball, a communication embodying extracts from the minutes of the Executive Committee which, he states, will correct errors in the statement published by Dr. Joel Foster and others. The pressure on our columns will not allow us to publish the secretary's communication in this issue, but we shall present it to our readers next week. In the mean time we can only repeat our hope that the differences between the officials of the asylum may soon be healed.
MINOR PARAGRAPHS.

HOSPITAL SATURDAY AND SUNDAY.

Measures have lately been taken to extend the machinery for collecting contributions to the fund in such manner as to admit of the matter being brought to the attention of individual artisans in the various trades through trade channels. At a meeting of representatives of the trades, held in the chapel of St. Luke's Hospital last week, arrangements were made by which workmen may subscribe small sums to a permanent fund for their own benefit, and a plan was adopted for a coupon system whereby auxiliary societies may draw on the general fund.

OPIUM SMOKING.

An iconoclast has arisen in Hong Kong, in the person of an English colonial surgeon, who maintains that the practice of smoking opium exerts no deleterious effect upon the system, or, indeed, any effect whatever, the injury done by it being of a moral kind only, leading to habits of dissipation and laziness. Dr. Ayers, the promulgator of this doctrine, founds his statements on a wide observation and some personal experience. He argues that the active constituents of the drug are destroyed in the process of combustion.

THE TEXAS "COURIER-RECORD" OF MEDICINE.

The second number of this new monthly journal, dated October, 1883, has reached us. It contains fifty-nine pages of reading-matter, made up of five original communications, a number of selected articles and abstracts, no fewer than fifteen editorials, and a varied assortment of miscellaneous paragraphs. The "Courier-Record" presents a creditable appearance. It is edited and published by Dr. F. E. Daniel and Dr. E. L. Stroud, of Fort Worth.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending November 13, 1883:

TYPHOID FEVER CONVEYED BY MILK.—Another instance of this wholly avoidable way of spreading typhoid fever has lately been reported from Fort Jervis, N.Y. An investigation is to be made under the direction of the State Board of Health.

AN OUTBREAK OF TRICHINIASIS was lately reported from Akron, O., due, it was supposed, to eating headcheese. Subsequent advice states, however, that microscopic examination has failed to reveal the parasite, and the inference is therefore drawn that the symptoms were due to a partially decomposed state of the meat.

THE CHOLERA IN THE EAST.—Two deaths from cholera took place in Alexandria on the 7th inst. On the 10th the disease was said to be subsiding in Mecca.

THE HEALTH OF BOSTON.—According to a recent statement by the Board of Health, there was a striking increase in the prevalence of infectious diseases during the month of October as compared with the same month last year, especially noticeable with regard to scarlet fever, of which there were 218 cases reported, against 48 last year.

MEDICAL MATTERS IN CANADA.—We learn from the "Union médicale du Canada" that the Montreal General Hospital has lately received a gift of $50,000 from Mr. George Stephen, the president of the Canadian Pacific Railway, to cover the cost of contemplated additions to the building; also that the Hon. Donald A. Smith has endowed one of the chairs in the Medical Faculty of McGill University in a like sum. The same journal states that the Laval University course in medicine was opened October 17th, and that the dormitory system is obligatory with all the students not residing in Quebec.

A CONVICTION UNDER THE MEDICAL PRACTICE ACT.—On complaint of the Medical Society of the County of New York, one "Dr." P. B. Proctor has been convicted of illegally practicing medicine, and fined $100. His diploma is said to have been issued by "Paine's University of Medicine and Surgery," of Philadelphia, and it lacked the endorsement required by law.

THE NEW YORK POLYCLINIC.—Dr. Allan McLane Hamilton has been appointed professor of diseases of the mind and nervous system.

DAWNTOWN MEDICAL COLLEGE.—The annual commencement took place on Tuesday, the 13th inst. The number of the graduating class was forty, being the largest for many years past.

A STATE OF PINEAL is soon to be set up in Paris by the Société médico-psychologique, pecuniary aid having been given by the Minister of Fine Arts and the Municipal Council. The sculpture, by Ludovic Durand, represents Pinel in his official robes, holding some broken iron in his hand, at his feet crouches an insane girl, with her eyes fixed upon her liberator. The head of Pinel is said to be strikingly expressive of the great alienist's lofty character.

THE NEW YORK SKIN AND CANCER hospital.—An examination of candidates for the position of House Physician will be held at the hospital, on Friday, the 23rd inst., at 3 p.m. For information, application may be made, before the 20th, to the secretary of the medical board, Dr. G. H. Fox, 18 East Thirty-first Street.

Bulbar Paralysis, especially with regard to the Constancy of its Lesions and its Difference from or Identity with Progressive Muscular Atrophy. 9. The Curability of Tabes Dorsalis. 10. The Influence of Syphilis in the Production of Tabes Dorsalis. 11. Landry's Paralysis an Essential Disease, or simply a Symptom which may be produced by Different Pathological Processes? 12. The Value of Nerve-Stretching as a Method of Treatment.

The Late Dr. Thuillier.—We lately recorded Dr. Thuillier's death from choler in Egypt, whither he had gone as a member of a French commission appointed to investigate the outbreak. A fund is now being raised for a testimonial in his honor, and a tablet has been placed in the vestibule of the École normale in Paris, bearing this inscription: Louis Thüilli, mort pour la science, Alexandrie, 1883.

The de Candolle Botanical Prize.—Professor A. de Candolle, of Geneva, Switzerland, offers a prize of 500f. for the best essay on any genus or family of plants. Manuscripts, in Latin, French, German, or Italian, should be sent to Professor de Candolle before the 1st of October, 1884.

OBITUARY NOTES.

J. MARION SIMS, M. D.—Dr. Sims died, quite suddenly, on Tuesday, the 18th inst., at his house in Madison Avenue. For two years or more he had been out of health much of the time, as the result of a severe attack of pneumonia, and on several occasions his condition was considered precarious. During the past summer, however, and since his return from Europe, but a few weeks ago, it seemed that he had regained his accustomed vigor. He was able to attend to his practice, and it is even said that he visited a patient on Monday evening. Tuesday morn- ing he rose as usual, and made no complaint of illness, but in the course of a short time Mrs. Sims noticed that he looked ill, and at once summoned her son, Dr. Harry Marion-Sims, to his father's assistance. The son, who was in the house at the time, reached the room only to find his father dead. It is supposed that dis- ease of the heart gave rise to the fatal attack.

James Marion Sims was born in Lancaster District, S. C., January 25, 1813; consequently he was in his seventy-first year at the time of his death. He received the degree of bachelor of arts from the South Carolina College in 1832, and began the study of medicine in Charleston. He was graduated from the Jefferson Medical College, of Philadelphia, in 1835, and entered into practice a year later in Montgomery, Ala. While in Mont-gomery he devoted a great deal of ingenuity and perseverance to improving the operation for genito-urinary fistula. Although he originated nothing with regard to the operation that had not been known and practiced before, it is certain not only that the procedures he brought into vogue were really the fruit of his own ingenuity, but that his genius systematized them and demonstrated their importance. Practically, then, we owe the modern operation for the repair of these injuries to him. In those days such fistulae were quite common, from lack of pre- ventive measures that we now see the necessity of adopting in midwifery practice. Whoever showed that they could be re- paired, and how it could be done, was, therefore, a benefactor of his race to an extent that it is not easy for the rising genera- tion to conceive of, for vesico-vaginal fistula is now an uncom- mon ailment.

It was during Dr. Sims's residence in Montgomery, also, that he discovered the great utility of the perineal retractor as a vaginal speculum. The immediate occasion of the discovery was accidental, but the incident that led to it would, it is safe to say, have been followed by no such result had it happened to a man destitute of Dr. Sims's remarkable and almost feminine keeness of perception. It is true that in this matter, too, he had been in a certain sense anticipated, but it was he, and he alone, who first perceived the immense advantages that gynecology would derive from the general use of an instrument acting on the prin- ciple of perineal retraction. Sims's speculum has worked a revolu- tion in gynecology.

Montgomery was now too small a field for a man enthusiasm- tic over his achievements and over what they seemed destined to lead to. A continent soon proved too narrow, and it was not long before he was teaching gynecological surgery in one after another of the great capitals of Europe. The speculum was invented in 1845; in 1853 Dr. Sims took up his residence in New York, and here, except for the years that he was abroad during the late civil war, and his frequent shorter visits to Eu- rope, he has since worked and taught. It is here that he may truly be said to have founded the American practice of gyneco- logy; literally, he founded the Woman's Hospital, the nursery of gynecology in America.

It is unnecessary to trace Dr. Sims's further career—his tri- umphs and the honors that have fallen upon him—for it forms an integral part of the history of American medicine, and is written in the memories of all who know that history. Al- though never a professor, he was in the highest degree a teacher. He was phenomenally fertile in suggestions, many of which have been followed out by others with such advantage that not a few features in the gynecological practice of the present day are really attributable to him with which perhaps he himself had forgotten his connection; had he personally explored a tithe of the channels into which his ingenuity forced him to cast a glance, ten lifetimes would not have sufficed for the task. He was not a voluminous writer; nevertheless, in the course of his life he contributed many important papers to the medical journals. His book, "Clinical Notes on Uterine Surgery," was published in London in 1866, and in New York the following year. Fragmentary as it was, it was so palpably original from cover to cover that it made a profound impression. It was translated into several European languages, and has been re- ferred to with the greatest deference by all subsequent writers in gynecology. Dr. Sims occupied many positions of honor in the profession, and his addresses, chiefly as the president of various learned bodies at different times, including the Ameri- can Medical Association and the American Gynecological So- ciety, of which latter he was one of the founders, were all re- markable for grace of language and weightiness of matter. There was never anything commonplace in what Sims said; it always made an impression.

As a surgeon, Dr. Sims's most noticeable characteristics were ingenuity and boldness. He was such a master of his art that he was a library unto himself. It is too soon yet to say what is to be the final result of his influence on surgery; but this much at least may be said, that he urged gynecology ahead much more than a generation—he drove it through an experi- ence that it might otherwise have had to crawl through. It is quite reasonable to suppose that many of his teachings will be reversed, but in their fundamental features the doctrines and the procedures he taught will not soon lose their prominence.

As a man, Dr. Sims's virtues were such as gained him the respect and admiration of two hemispheres. He stood aloof from the terrible struggle through which the nation passed dur- ing the War of Secession, and without forfeiting the esteem of that section of the country against which his sympathies were enlisted. At a subsequent period, in aid of a foreign commu- nity, he earned laurels of which we are all proud. He had antagonists, and sometimes found himself in a storm of contro- versy, as was exemplified not long ago in the war of pamphlets that accompanied his withdrawal from the Woman's Hospital.

LETTERS TO

THE EDITOR.

551

Bitter as portions of these documents were, it is to be doubted if any of his opponents ever quite lost their fondness for him.

In debate, he was sometimes heated to a degree that threatened rancor, but he was also chivalrous. Those who witnessed what took place when, at a meeting of the Medical Society of the County of New York, held not long before the death of the lamented Peaslee, he pushed his invective to the verge of the unbearable in denunciation of Peaslee's teachings in regard to inoculation and discussion of the cervix uteri—those who were present at that memorable scene need no reminder either of his biting sarcasm or of his generous apology. As period after period of Sims's eloquence rolled out, Peaslee's pale, thin form, motionless and impassive as an icicle, drew every eye to itself. Men held their breath, dreading lest these two great men should come to unequal behavior; but it was Southern aridor against Yankee repose. A voice called Sims to order, but Peaslee rose slowly and majestically from his seat, and, in measured words that betrayed not a trace of emotion, quietly said: "Mr. President, I beg that Dr. Sims be not interrupted. When he has finished, I shall have something to say." When the time came, he did have something to say; he said it with the extreme of precision and propriety, but every sentence told. Sims soon saw that he had misinterpreted his antagonist, and now it was Southern chivalry against Yankee logic. With every mark of nobility in his mien, Sims jumped to his feet, and, offering his hand to Peaslee, said, in substance: "I see that I have been unjust, but Dr. Peaslee will take my word when I declare that it was not intentionally that I wronged him. The paper I have read to-night is already in type, but it shall never be published." The two men shook hands, and the paper never saw the light. The logical victory was with Peaslee, but Sims carried home with him the winnings of heroism.

In Dr. Sims's death the American profession has lost a giant, and the world at large a noble man. It needed not a legal enactment to perpetuate the name of Marion Sims; it will be handed down through all time to come.

MARBURG S. MEADE, M. D., OF NORTHFIELD, MASS., died on Tuesday, the 12th inst., at the age of eighty-one. He was born in Chesterfield, N. H., June 4, 1892, and for the last half century had practiced medicine in Northfield. He was a member of the Massachusetts Medical Society, and one of the most prominent and popular practitioners in Franklin County. In 1853 he was a member of the State Legislature.

Letters to the Editor.

MEDICAL LEGISLATION IN OHIO.

CINCINNATI, October 29, 1882.

To the Editor of the New York Medical Journal:

Sir: Your Cincinnati correspondent, in your issue of the 27th, speaking of the medical bill that was defeated in the Ohio Legislature last winter, thinks that the "irregulars" followed Dennis Kearney's advice and "pooled their issues" against it, because the bill did not specify the different schools in medicine that were to be recognized in the proposed Board of Health. He includes "physio-medicals" among these opponents. In this he is mistaken. I believe myself entitled to speak for the physio-medicals of Ohio, and ask space to correct the error of your correspondent. We were urged to oppose the bill, but positively refused. The wording of the bill left it open to suspicion, and the bill might possibly have passed had its friends consented to change its phraseology so as to remove that suspicion. Nevertheless, it was favored by physio-medicals, who preferred to believe it was intended honestly and would be executed fairly.

The present Ohio medical law is worse than your correspondent states. It allows every county society to license its members without check; the licenses may be perpetual, and there is nothing to encourage or compel medical education. Any band of ignoramuses may incorporate a society, and proceed to issue licenses as if it were a college. And, through our general law on education, a college charter can be obtained very easily; there is no supervision of such charters, and they may be used ad libitum to cover and make legal the sale of diplomas. The profitable business of diploma huckstering is thus sanctioned and protected by the laws of Ohio.

Physio-medicals are not responsible for this status of our laws. We opposed the present law, because we saw that it would make Ohio the asylum of 'medical charlatans, as it has done. We worked against it, because it is calculated to encourage ignorance and cast a stigma on medical science in Ohio. Since that law was passed I have repeatedly, through the public press, shown its fallacy and urged a radical change in our medical statutes. The character of the law that I have advocated for many years is as follows:

Create a State Board of Health on which there will be just representation of each school of medicine that has in the State a chartered college maintaining an honorable educational standard in medicine, and an incorporated State society. Among its duties, let this Board supervise medical practice in determining a standard of medical education by which to judge colleges in and out of this State. Let no college in the State have power to issue medical diplomas, except as its applicants for graduation passed a satisfactory examination before this Board, and had the authority of the Board indorsed on each diploma. Empower the Board to issue licenses to graduates of honorable colleges out of the State, and to issue limited licenses to non-graduates who pass a satisfactory examination before it. In all examinations by the Board, let questions on anatomy, physiology, chemistry, pathology, toxicology, obstetrics, surgery, forensic medicine, diagnosis, and similar topics where medical men have no differences, be passed upon by the entire Board; but on therapeutics, materia medica, and other points where the schools differ, let the representative of each school decide upon the candidates of that school.

By such a law the usual fear of class legislation would be set aside; and educated gentlemen could meet on common ground without compromising their personal opinions—as Presbyterians, Methodists, Baptists, and other religiousists meet in bodies for general work. No one school would be at the mercy of others. Incompetency and charlatanism would be driven to the wall, and the public would not be prevented employing any competent medical man that suited them. Fraudulent colleges would be stopped, and colleges giving an inadequate education would be forced to raise their standard or to close their doors. Charters could no longer be used for corrupt purposes, and every physician would have to graduate in a worthy college at an early day.

This is the law that the physio-medicals of Ohio have long advocated. We believe that it covers the entire ground, and contains the very essence that should reside in every law—justice to all. It deprives no man of his convictions or his rights, but summarily prevents ignorant and corrupt men from preying upon the lives of others. Physio-medicalists are willing to let their men and their colleges stand or fall under the fair working of such a law as this. In the interests of humanity, and for the honor of medical science, we are ready and anxious
to join hands with all honorable men—be they regulars, homoeopathists, or eccentrics—to advocate such a law before the Ohio Legislature next winter.

Yours respectfully,
WM. H. COOK, M. D.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

A staled meeting was held November 15, 1883, FORDYCE BARKER, M. D., LL. D., President, in the chair.

The Statist-ical Secretary announced the death of the late Dr. J. MARION SIMS.

The President spoke as follows: By the death of Dr. Marion Sims, the Academy of Medicine, the profession of this city, and, I may well add, the profession of the country, have lost their most original and brilliant genius in the department of surgical gynaecology. This will be conceded by all. Had circumstances forced him to equal activity in other branches of surgery, his fertility and promptness in practical suggestion, his intuitive power of conception of new means to secure any desired result, his endowment of invention, and wonderful mechanical adroitness would undoubtedly have given him equal eminence in all its departments. No one can be compared with him in his own sphere, in which he achieved such great distinction, except the late Sir James Y. Simpson. An intimate relation with both for many years may, perhaps, justify me in saying that there were very many points as to their intellectual and moral qualities which were strikingly characteristic of both. These resemblances were much more numerous than the points of contrast. In the future the greatest fame of one will rest on his courage, and, I may even say, audacity, in successfully introducing anaesthetics to relieve the agonies of parturition; in the other, by his genius in devising new methods of physical exploration, and new surgical procedures which effect cures of lesions, which before could neither be correctly diagnosed nor successfully treated. In this alluding to the greatest achievements of the two, I should also add both were incessant, zealous workers, who for many years were constantly making positive contributions to our science and our art, many of which would alone establish their claim as great men in our profession; the former perhaps adding more to our scientific literature, and the latter more to the advancement of our art. Neither of them was reluctant to have his good work appreciated. To-morrow morning, I doubt not, every Fellow of the Academy, whose engagements will permit, will be present at the funeral services of our late most eminent associate. The Chair, in accordance with our by-laws, will designate Dr. T. ADDIS EMMET to read a memoir at the first meeting of the Academy in January.

On TYPHOID FEVER in New York was the title of the paper which was read by Dr. FRANCIS DERFAND.

By the mortality tables of the Board of Health he had found that for many years there had been an annual mortality of from one to two hundred from typhoid fever in the city of New York. In the years 1863 and 1866, when typhus fever prevailed, the mortality ran up to 500 and 600 yearly. Since that time the yearly mortality had been from 200 to 400. In 1879 the mortality was as low as 178. In 1881 it was 446. In 1883, up to October 1st, 274. It was most prevalent in the summer and beginning of the autumn, but no month was free from the disease. From January 1, 1877, to October 1, 1888, 1,305 cases had been treated, in all the hospitals in the city. In 1877 the total number in the hospitals was 135 cases, with a mortality of 27 per cent. In 1878 the total number was 124, the mortality 27 per cent.; in 1879 the total was 114, the mortality 29 per cent.; in 1880 the total was 110, the mortality 30 per cent.; in 1881 there were 319 cases, with a mortality of 22 per cent.; in 1882, there were 315 cases, with a mortality of 26 per cent.; in 1883, up to the 1st of October, there were 190 cases, with a mortality of 26 per cent.

Most of the cases occurred in adults; the number of children admitted to the hospitals was too small to arrive at a conclusion as to the relative frequency of the disease at the different periods of life. In adults, however, it occurred most frequently between the 20th and 30th years. He had had little opportunity for getting at the true etiology of the disease. In a considerable number of cases it had originated out of the city.

At the autopsies, the regular lesions had been found to exist, more or less positively marked. The solitary and the agminated glands of the small intestine had been found either swollen or converted into ulcers, with adherent sloughs, or the ulcers were completely cleaned off at the time of death, and even cicatrizing. The changes, however, even in the worst cases, were confined to the glands mentioned. The large infiltration of the small intestines which occurred in some epidemics had not been observed. In some cases the intestinal lesions were inconsiderable. Peritonitis with perforation had occurred in only a small number of cases, and in one of these it was at the seat of the vermiiform appendix. The colon was involved only in a few instances. In these the enlargement and sloughing of the solitary glands were very decided. In the stomach multiple new growths of lymphatic tissue with ulceration were seen only in a single case. The mesenteric glands were swollen in all cases in a degree corresponding to the intestinal lesions. When the glands were unusually swollen there was sometimes a little fibrin on the peritoneum over them, and in one case the peritonitis had become general. Suppuration of the mesenteric glands was observed in two cases. The spleen was soft in all the cases, and usually enlarged; in some instances it was of normal size, and in some even smaller than normal. In one case, that of a boy, it had ruptured. Inflammation of the colon, with symptoms of dysentery, existed in several cases; in one, the dysentery had proved fatal, and the lower two thirds of the colon were found coated with fibrin. Suppuration of the parotid glands was not seen in a single instance. The liver was enlarged, in many cases, with some swelling and degeneration of the hepatic cells. The kidneys, also, as a rule, showed swelling and degeneration of the epithelial cells, and more or less enlargement of the entire organ. Such changes were sometimes accompanied by albumin in the urine during life, and casts in a few cases. The heart was firm, with normal muscular tissue, in the majority of cases; the characteristic flabby heart, with degeneration of the muscular fibers, was seen in only a minority of the cases. The lungs manifested a variety of changes: congestion of the larger bronchi, with increased production of mucus in many cases; severe bronchitis and broncho-pneumonia only in a few; lobar pneumonia in two. A moderate degree of hypostatic congestion of the posterior portion of the lungs was common. No recent lesions were found in the brain or its membranes. The voluntary muscles, especially those of the anterior abdominal walls, presented characteristic granular and waxy degeneration is only a moderate proportion of cases. It was evident that the anatomical type of the disease, as it had prevailed in New York during the past few years, was not a severe one. The remarks made were based upon the notes of 102 cases, all undoubtedly examples of typhoid fever occurring during the past five years. During this period there had been many cases of fever of an obscure nature.
A distinct history of the prodomic period was obtained only in 18 of the 102 cases. In these the condition was much the same—langur, headache, indisposition to mental or bodily exertion, loss of appetite, constipation or diarrhoea, irregular chilliness, sometimes bronchitis. The duration of this period had varied from four days to several weeks. The character of the invasion was ascertained in 83 cases. In 37 there was a chill on the first day; mild or severe; it was sometimes repeated on successive days. It was followed by febrile movement, often accompanied by headache, vomiting, nosebleed, and diarrhoea. In 25 cases diarrhoea was among the first symptoms accompanied by fever; sometimes also by headache or epistaxis. Altogether, there were 44 cases in which diarrhoea was one of the first symptoms. In three of these blood was mixed with the passages during the first few days. In 15 cases headache and fever marked the onset. In six bronchitis, with cough and expectoration, was the most prominent feature during the first week. Pain in the right iliac fossa, or above the abdomen, was said to exist in many cases. In the remaining cases it could not be determined exactly how the disease began.

The record of the temperature during the first week was very incomplete. In the cases in which it was taken, during the first week or the latter part thereof, it did not rise in the regular and gradual manner described by some authors. Transfer to the hospital seemed often to produce a rise of a degree or two in twenty-four hours. In some patients there was a morning chill, followed by afternoon fever, and then sweating. In some there were sudden falls of the temperature, continuing for six, twelve, or twenty-four hours, during the first week. In the second week the temperature approached nearer to the type of a continuous fever with moderate morning remissions; sometimes these remissions were decided. In other cases the morning temperature was the highest for the twenty-four hours. In some instances the temperature fell to normal by the fifteenth day, and convalescence began; or, it might again rise after several hours, and the disease continue for several weeks longer. In the cases which terminated fatally in the second week, the temperature reached the highest point either just before death, or two or three days before, in which case it fell to 100° or 101° F. a few hours before death. During the third week the temperature ran much the same course as during the second. In the fourth it showed more marked morning remissions. In some instances, the temperature, having fallen for from one to three days, rose again and continued high one or more weeks longer. The height of the temperature was usually in proportion to the severity of the disease; but to this rule there were many exceptions. Some of the patients bore a high temperature much better than others. The pulse during the first week was regular, full, from 80 to 100. In the second and third weeks it became more rapid and feeble, sometimes dierotic; as a rule, the more rapid the more feeble; in some instances, however, it was both feeble and slow. Generally speaking, a rapid pulse was an unfavorable symptom, but sometimes the pulse continued rapid while the temperature was falling and convalescence approaching. Where death took place with a low temperature, the pulse was feeble and rapid. Where a slow pulse was associated with cerebral symptoms, the cases closely resembled cerebro-spinal meningitis. The appearance of the patients was usually characteristic; the expression was dull, the skin of the face was dusky, the checks were flushed, the mind was sluggish. The tongue was coated down the center with a tinge of white fur, which afterward became yellow-brown, and sometimes fissure occurred; in some, the tongue remained clean; moistening of the tongue was regularly one of the most trustworthy symptoms of approaching convalescence. Delirium of an active and well-marked type was present in 41 cases, and indicated a severe form of the disease. Lesser degrees of delirium, especially at night, were much more common. There was diarrhoea in 82 cases, and in 44 it began during the first days of the disease. In 11 cases it stopped altogether after the first week. In 20 cases it lasted only a part of the second week. In 51 it continued throughout the entire disease. Constipation throughout the whole course was observed in 18 cases; it was apt to be associated with an excessive degree of tympanites. The eruption was regarded as being well marked in only 44 cases; but Dr. Delafieid doubted whether accurate observations were made with regard to this point. The eruption had been more constant the present autumn than for several years past.

With respect to complications, hemorrhage from the bowels occurred in 23 cases; in six of these it seemed to be the immediate cause of death. The hemorrhage assumed the characteristic form in most instances, but in three cases the discharges were streaked with blood from the very onset of the disease. In one instance the bloody discharge from the bowels was accompanied by blood in the urine and extravasation of blood under the skin. In two there was a constant running away of blood from the rectum in the sixth week. In the cases in which characteristic hemorrhage took place it was usually followed within a few hours by a well-marked fall in the temperature. Hemorrhage was always an alarming symptom. Of twenty-three patients in whom it occurred, nine recovered. In three cases there was a well-marked postural eruption of the skin, which, however, proved merely a discomfort to the patient. Suppurative inflammation of the middle ear, with discharge of pus, occurred in five cases; severe pharyngitis, with production of false membrane, in one case during the first week of the disease; a moderate degree of catarhal pharyngitis in a large number. Bronchitis and a severe type of broncho-pneumonia were observed in 24 cases; in 16 it occurred during the first week. In some the bronchial symptoms were more marked than the typical typhoid symptoms. In three it seemed to be the immediate cause of death. There was lobar pneumonia in two cases, which seemed to be the immediate cause of death. Repeated attacks of feeble heart action and syncope occurred in one instance, the patient dying in one of the attacks. Peritonitis occurred in four cases, being caused by perforation in two. Thrombosis of the femoral vein, with swelling of the leg and thigh, occurred in one case. Dysentery set in after convalescence in five cases, proving fatal in one instance.

The duration of the disease was ascertained in 61 cases; in 1 case convalescence began on the 16th day, in 4 cases on the 18th day, in 6 at the end of the third week, in 15 in the fourth week, in 12 in the fifth week, in 4 in the sixth week, in 4 in the seventh, in 1 case in the eighth, in 9 cases in the ninth, in 1 case in the tenth. There were well-marked relapses in 7 cases, all of which ended in recovery. Of the 102 cases, 94 proved fatal. In 18 death seemed to have been directly attributable to the disease itself. In most of these the temperature ran high—from 104° to 107° Fahr., but not continuously so. The pulse was always feeble and usually rapid. One patient died in collapse, the temperature in the rectum being but 95°. A thorough sponging with ice had been made.

The treatment varied in the different hospitals. In mild cases, in general, the patients were simply put to bed and given milk diet. Some of the hospitals employed peptonized milk. Alcohol in one form or another was given by some physicians in every case: by others its use was reserved for feeble heart action. Besides alcohol, digitalis, convallaria, and caffeine were frequently employed as cardiac stimulants. Quinine was given to nearly every patient in some of the hospitals; in others it
was given only when the temperature went above 103°; in still others it was hardly resorted to at all. General bathing during the past year seemed to have been almost entirely abandoned. One or two years ago it had been employed to a considerable extent in several of the hospitals. Sponging, or the use of the Kibbee cloth, was employed in some of them to a considerable extent; in others, the use of cold water in every form, to reduce the temperature, was abandoned. For typhus fevers, tarpeints, externally or by the mouth, was often employed. For hemorrhage from the intestines opium and ergot were in ordinary use. When the diarrhea was excessive, opium, with bismuth or pepticin, and a solution of the acetate of aluminium, were most employed. In one hospital large doses of calomel were given with the idea of aborting the disease. Salicylate of sodium, henzoate of sodium, and a combination of carbolic acid and tincture of iodine, given with the idea of acting upon the poison of the disease, were very little used in the hospitals.

Dr. Alfred L. Loomis had been interested to know what definition Dr. Delafield would give of typhoid fever. The paper had been a painstaking and truthful record of what had been called typhoid fever as it prevailed in New York to-day. Dr. Loomis then reviewed in brief the history of the fever as Dr. Delafield had recorded it, and stated that it did not correspond to that given of typhoid fever by Liebermeister, and others, as it existed on the continent of Europe. By those writers, the disease was represented to have a typical range of temperature, gradually rising during the first week, an even temperature during the second week, remittent during the third, intermittent during the fourth; a characteristic rose-colored eruption appearing between the sixth and the tenth days, each spot remaining for three days, then disappearing, perhaps a new crop taking the place of the old; a pea-soup diarrhea, a specific poison, that is, originating in matter contaminated by the excrements of the typhoid patient. These characteristic symptoms had not been regularly present in the disease described by the author of the paper, nor had they been present in the cases of so-called typhoid fever which he, Dr. Loomis, had observed in this city for several years past. In the cases which he had seen, the temperature had manifested irregularities, the diarrheal discharges had not been characteristic, there had not usually been an eruption, at least not rose-color; he had been unable to trace the disease to a definite cause or a definite germ. He then read the history of the disease as it had prevailed in his wards at Bellevue Hospital this year, the histories having been prepared by the patient himself. In reply to a question by the President, whether he employed a laxative when constipation was present, Dr. Loomis said he did not.

Dr. F. P. Kinney quoted a statement made by Sir William Jenner some years ago, that one cause of constipation in typhoid fever was believed to be deep ulceration of the intestinal glands. He had studied the cases which had been observed at St. Luke's Hospital, with regard to this and other points, and had concluded that constipation was an unfavorable condition, and might be even of dangerous import. It had the practical bearing that, as he believed, laxatives should not in any case be given by the mouth, as his limited observations confirmed the statement of Jenner. The bowels should be relieved by small enemata, if necessary frequently repeated, rather than the use of larger ones. He was disposed to regard the relapses as due to the remains of the typhoid poison, and not to errors in diet, or other accidental circumstances. His treatment consisted in rest in bed, plenty of pure air, a strictly regulated diet, and medicinal treatment only for special symptoms as they arose.

Dr. E. G. Janeway quoted statistics of typhoid fever as it had existed in New York for over a quarter of a century past, which went to show that the disease was not more prevalent at the present time in proportion to the population. He was of the opinion that what was called typhoid fever as it was at present prevailing was such in fact, and that, while the symptoms might vary more or less, they did so no more than in other contagious and infectious diseases. That the etiology corresponded to that given in the books was proved by several instances, in which at first, however, its origin could not be traced. During the outbreak at the Catholic Half-Orphan Asylum, a ward from which a part of the children obtained their drinking water was found to be contaminated, and when this was closed the epidemic ceased. In some epidemics diarrhea was common, in others constipation was more frequent, but similar pathological lesions were found in each, the characteristic lesions of typhoid fever as they existed in the intestines, though, perhaps, differing in severity. The mortality also varied in different epidemics. The European writers also described an atypical as well as a typical course of the disease.

Dr. T. A. McBride spoke of his experience at the Out-door Department of the New York Hospital. Whenever a patient presented himself with diarrhea he took the temperature, and almost invariably found it elevated, the spleen enlarged, the liver sometimes enlarged, and nearly always the eruption of typhoid fever. Some of the patients entered the hospital, and remained for a variable period of time, but usually the disease proved of a mild type. When hemorrhage occurred from the bowels, there was almost invariably albumin in the urine, unassociated with tube-casts. He had employed ka-raine for reducing the temperature, in seven-grain doses every hour, until the temperature fell to 101°, which it usually did in a short time; and, on the slightest signs of its rising again, the drug was administered. Ka-raine also usually produced copious perspiration after a few doses. He did not wish to reduce the temperature below 101° with the drug, lest a chill should occur. When used in small doses no bad results had followed. He had found the urine frequently to contain peptones.

Dr. Kinney had employed ka-raine in the manner suggested by Dr. McBride, and with excellent results. There was a tendency to almost immediate elevation of the temperature on ceasing the administration of the drug.

Dr. Howard P. Sheppard had employed sulphurous acid with benefit in cases of typhoid fever.

Dr. J. H. Enslow gave the statistics of some cases of typhoid fever observed in private practice.

The President said, with regard to laxatives in constipation, that, as a rule, he objected to administrying anything which would disturb the bowels, but, when constipation continued and became positively a discomfort to the patient, he gave a single dose of five grains of calomel well rubbed up with fifteen grains of bicarbonate of sodium, and had found it prove most beneficial.

Dr. Alfred C. Post inquired whether gurgling was observed in the right iliac fossa in cases where constipation was present. Dr. Delafield, in closing the discussion, said that it was known that typhoid fever presented variable symptoms in different cases, as was also true of other infectious diseases, and thought that Liebermeister had been the cause of much false impression in stating so positively a definite range of temperature and course of symptoms in general; his descriptions were more fixed, definite, and positively stated than the natural course of the disease warranted. He did not think that constipation had anything to do with the size or number of ulcers in the intestine. He also thought it doubtful if the lesions produced diarrhea, or whether this was not due more to other causes. Constipation was regarded as an unfavorable sign. He saw no reason why a laxative should not be given early in the disease, and he was in the habit of doing so, and with good results.
PROCEEDINGS OF SOCIETIES.

was better to give a laxative than to allow the colon to become distended with faecal matter, as it often did. In answer to Dr. Post's question, there were usually tympanites and gurglings in the cases in which constipation was present. He agreed with Dr. Kinnicutt that the relapses were probably due to the typhoid-fever poison rather than to incidental causes.

NEW YORK SURGICAL SOCIETY.

A stated meeting was held October 9, 1883, Thomas M. Markoe, M.D., President, in the chair.

Cicatricial Contraction from a Burn.—Dr. A. C. Post presented a boy, two and a half years of age, who was admitted to the Presbyterian Hospital on the 17th of September. One year previously he had been burned by falling against a stove. Only one finger of the left hand was injured—namely, the index, which was bent and held by a cicatricial band. The right hand was burned much more severely; the thumb escaped, but all the fingers were contracted, the amount of contraction diminishing from the index to the little finger. The last joint of the index finger was bent at quite an acute angle. Dr. Post divided the bands of cicatricial tissue through the entire thickness of the incised parts at intervals of about three or four millimetres, and was able to bring the fingers into a straight position. The operation was performed on the 16th of September upon both hands. The splint was removed from the left hand on the 24th of September, and had not been reapplied. The splint had not been omitted from the fingers of the right hand, although they were perfectly straight and the tissues were flexible. The treatment consisted in free multiple incisions through cicatricial bands, forcing the fingers back and applying a narrow splint of marble iron covered with tissue-paper, extending upward to about the middle of the forearm. Recently Dr. Post had treated the operation wounds in this class of cases by first dressing the parts with carbolized oil or vaseline, and at subsequent dressings sprinkling them very freely with nitrate of bismuth to fill up all the interstices between the incisions. He had found that the bismuth dressing answered an exceedingly good purpose. The granulations had been kept down in this manner, and the wounds had been maintained in a remarkably healthy condition, with but very little suppuration.

Excision of a Portion of the Spinal Accessory Nerve for Spasmodic Torticollis.—Dr. H. B. Sands presented a man, thirty-nine years of age, who had consulted him in May, 1882, on account of the disease, which first appeared nine months previously. The attacks of spasm were at first less frequent than they became subsequently, and produced a rotary movement of the head, causing it to turn forcibly toward the left side. No effort upon the part of the patient could prevent this movement. In the beginning, the turning of the head occurred about once in three minutes; subsequently it became more rapid, and it was estimated that the intervals between the movements did not exceed three seconds. Before he came under Dr. Sands' care he had been treated by Dr. Seguin, who had thoroughly administered hyoscymine, the bromides, atropine, and other remedies, but without any beneficial result. The patient when Dr. Sands first saw him was quite weak, and the contraction of the sterno-mastoid upon the right side was almost constant. It was decided to excise a portion of the spinal accessory nerve, which was assented to. In a previous operation he had followed the plan suggested by the late Mr. De Morgan, of making an incision along the posterior margin of the sterno-mastoid muscle, exposing the nerve and tracing it forward, but he had found this procedure difficult and unsatisfactory. He therefore determined to try an operation by which the nerve could be reached not far from its exit from the skull, just in front of the point where it penetrates the muscle. He made an incision three inches in length along the anterior margin of the sterno-mastoid, beginning close to the mastoid process. After exposing the muscle and turning it outward, he readily found the spinal accessory nerve, where it crosses the internal jugular vein, which was felt, though not seen, during the dissection. A piece of the nerve one fourth of an inch in length was excised, and the wound was closed by sutures and covered with an iodiform dressing. Healing by adhesion was complete on the 24th day of May, nine days after the operation. Immediately after the operation the sterno-mastoid ceased to contract, and it was now paralyzed and atrophied. The patient, however, did not recover immediately from the torticollis, as there still remained a marked tendency to rotation of the head toward the left side, this being due mainly to contraction of the left splenius muscle, which could be felt as a thick, hard mass. On the 7th of June, however, the condition of the patient was very much improved, and by the middle of June he was nearly free from spasm. For six months afterward he continued to suffer at intervals, and regained entire control of his movements only after going into the country, and improving his general health. Even now he occasionally found that his head was disposed to turn to the left side, but he had no difficulty in preventing this movement, or in turning to the right. Considering his distressing condition when he came under Dr. Sands' observation, the result must be regarded as quite satisfactory.

Dr. Sands also presented another patient, aged thirty-one, upon whom he had performed a similar operation and removed two fifths of an inch of the spinal accessory nerve on the 25th of June of the present year. The patient had been engaged as an expressman for fourteen years, during which time it had been his habit to carry trunks upon his right shoulder, turning his head well toward the left side, thus, in his opinion, laying the foundation of his disease. Four or five months before he came to Dr. Sands he began to experience some difficulty in turning his head to the right side, and also became subject to clonic spasm of the muscles which turn it to the opposite direction. Seven weeks before the operation he was treated by the application of the actual cautery along the course of the affected muscle, but without any good effect. This treatment, however, was followed by tonic spasm of the muscle, so that from that time there was no longer a rotary movement, but an extreme rotation toward the left side, so that his face looked over the left shoulder. The case then resembled one of ordinary torticollis more than one of clonic spasm. In this instance the discovery of the nerve at the time of the operation was more difficult than in the former one, and the internal jugular vein was more distinctly exposed. The wound healed without suppuration, and on the 16th of July the man left the hospital much improved. As in the other instance, the sterno-mastoid and trapezius were paralyzed, yet recovery was gradual. For several weeks he had some difficulty in keeping his head in the proper position. He was now, however, quite well. In this case, too or three weeks after the operation it was noticed that the head was still inclined to turn toward the left side, the left splenius, the tracheo-mastoid, and the inferior oblique being probably the muscles contracting.

Dr. Sands believed that it was usual in cases of spasmodic torticollis to find that the sterno-mastoid was not the only muscle affected. In a case reported by Mr. De Morgan many muscles were involved, including those of the eyeball. Dr. Sands had seen a case about a year ago in which the integument could be observed to be raised during spasmodic contractions of the omo-hyoid. The cure by division of the nerve seemed to be effected gradually, and to be due to the cutting off of the nervous supply of one of the principal muscles involved in the disease. He
did not feel certain of a permanent result in either of these cases, but the condition was now such as to afford great encouragement. He regarded the operation by dividing the nerve anteriorly as far better than that suggested by Dr. Morgan, because by cutting in front the nerve could be reached before it divides into two branches, and a portion of the common trunk excised quite near to its exit from the skull.

Dr. F. Lange had had a similar case, in which he gave temporary relief by stretching the spinal accessory nerve. The benefit remained for only a few weeks. It was evident that the clonic spasms were mostly due to the action of the muscles at the back of the neck on the opposite side, and he therefore finally cut through the principal muscles upon the opposite side of the neck, which gave an apparent cure for a shorter period of time. But the trouble then recurred, although to a somewhat lesser degree; what the final result was he was unable to state. It was certain that in this case the action of the sternomastoid was entirely paralyzed by the stretching of the nerve. The muscle had been divided frequently by other surgeons previously to the stretching, yet it acted well before Dr. Lange performed his operation.

**FOREIGN BODIES IN THE AIR-PASSAGES.—Dr. R. F. Weir presented a patient and related the case. [The case has already been given in this journal. See p. 404.]

Dr. Weir also reported a case, that of a child, two years of age, who inhaled a coffee-bean two days previous to the one just reported, and in whom he performed also tracheotomy for its extraction. When the patient was first seen the house surgeon was about to perform tracheotomy, but just as the skin was divided the child suddenly ceased coughing, and breathed so easily that the operation was abandoned on the supposition that the foreign body had been removed. Two hours later, however, when Dr. Weir first saw the case, the child was breathing with considerable difficulty. He then opened the trachea, searched above and below, but did not feel the foreign body. A suture was introduced on each side of the opening, so that the edges of the wound could be held open if at any time it became necessary to explore the trachea further. The progress of the case proved that this was a wise precaution, for, soon after, the child was found breathing very peculiarly, the tube which had been introduced was withdrawn, the wound in the trachea was held open by means of the sutures, and out popped the roasted coffee-bean considerably swollen. Pneumonia developed, and the child died on the fourth day afterward.

Dr. Sands said that an unsuccessful attempt to explore the trachea by means of the finger in Dr. Weir's case recalled to his mind a case which occurred many years ago in St. Luke's Hospital. The man had a portion of an India-rubber tracheotomy-tube lodged in the left bronchus, and some difficulty was experienced in determining exactly where the foreign body lay. In that instance Dr. Sands passed his finger down through the tracheal wound and immediately detected the foreign body just below the point of bifurcation. A forceps was then inserted and the foreign body extracted. Since making this discovery he had often demonstrated upon the cadaver that he could pass his finger into the trachea always as low as the place where it divides, often being able to cause the extremity of the index-finger to enter either bronchus a distance of half an inch.

The President remarked that these cases illustrated one point in diagnosis which had interested him. In a case which he had had some time ago, one in which a shirt-button had passed into the right bronchus, which he extracted with the forceps after tracheotomy, Dr. J. R. Leaming made the diagnosis as to the situation of the foreign body. In that instance the obstruction was manifestly in the two lower lobes of the right lung, the upper lobe being perfectly resonant, and the respiratory murmur distinct. In the case which Dr. Weir had now reported the position of the foreign body was determined by the fact that the whole left side showed absence of respiratory murmur. In the right bronchus, the bronchial branch going to the upper lobe sometimes came off very near to the bifurcation, and from this point there was quite a distance before the next division took place. It was between the first branch and the second point of division of the bronchus that the foreign body lodged when it entered the right bronchus. When it entered the left bronchus there was no branch until the tube broke into its final divisions, nearly two inches from the trachea, and, therefore, when this left bronchus was obstructed, the entrance of air to the whole of the left lung was prevented.

**REMOVAL OF THE ENTIRE TONGUE, THE SUBMAXILLARY AND SUBLINGUAL GLANDS, AND THE LATERNAL WALL OF THE PHARYNX by Koche's Method; Case.—Dr. W. T. Bull presented a man, forty-one years of age, who had been in good health up to four months before admission to the hospital. At that time he observed a small ulcer on the left side of the tongue, and at the same time a swelling under the jaw. Both increased rapidly in size, the tongue becoming hard about the edges of the ulcer, and causing severe pain at night and while eating. His appetite had continued good, and he had not materially depreciated in weight or strength. On examination, a ragged, excavated ulcer was found on the left side of the tongue about its middle, reaching upward to the dorsum, and backward as far as the palatoglossal fold, along which it extended to the mucous membrane covering the posterior edge of the internal pterygoid muscle. Its edges were indurated, its surface was sloughy, and the discharge was sanguineous. The submaxillary gland formed a mass of twice as normal volume, but was not hard nor tender. There were no other enlarged glands. A piece taken from the edge of the ulcer proved under the microscope to be epithelial. The operation was done August 11th, a preliminary laryngotomy having been performed, and the pharynx stuffed with sponges on strings. By raising a triangular flap, the submaxillary triangle was explored, the facial artery and vein were ligated, the submaxillary gland was removed, then the lingual artery and vein were tied, and the sublingual gland, with one half the tongue, was removed with the scissors as far back as the hyoid bone. The other half was removed in the same way, as well as the mucous membrane of the pharynx beyond the posterior pillar of the fauces, and as low down as the hyoid bone, including that covering the inferior and posterior part of the pterygoid muscle. A hard, enlarged gland was now found under the sternomastoid, closely adherent to the carotid sheath, and was extirpated. Several bleeding spots were touched with the cautery.

The only nourishment given during the first twenty-four hours was two ounces of beef peptonoids with whiskey. After that the stomach-tube, with a funnel attached, was introduced twice daily, the ganze in the mouth being removed each time. Between two and three pints of milk, and afterward beef-tea, soup, and milk-punch, were administered at one time. The iodoforin ganze was not changed till the sixth day. After that the ganze in the mouth was discontinued, and the iodoforin ganze removed once or twice daily, the granulations being sponged with the boro-salicylic solution. There was no constitutional reaction, the pulse not going above 90, nor the temperature above 99°F. On the fourth day the man sat up for several hours. On the seventeenth day he took food himself, although the wound would admit three fingers. The discharge was moderate, and never offensive. The wound was of the size of a goose-quill at the end of five weeks, reduced to a trifling sinus a week later, and entirely closed at the end of seven weeks.

**(To be concluded.)**
NEW YORK NEUROLOGICAL SOCIETY.

A regular meeting was held October 12, 1883, the President, Dr. William J. Morton, in the chair.

THE NEUROTIC ORIGIN OF PROGRESSIVE ARTHRITIS DEFORMANS.—Dr. Leonard Webber read a paper in which he briefly recapitulated the symptomatology and etiology of the disease, and stated his views concerning its nature. He said that, among the comparatively large number of cases of arthritis deformans which he had seen in the course of the last twenty years, he could not but recognize sorrow and grief, fright, irritation, and exasperation of nerve-centers by sexual indulgence and the leading of a dissolute life—factors just as potent in producing the disease as rheumatic influences, if not more so. Again, remembering the symmetrical appearance and progress of the disease in most cases, no more plausible explanation seemed possible than the supposition of causes located in the central nervous system. The neuralgic and tropho-neurotic symptoms also supported this view, though it was not to be forgotten that in a spine stiff and deformed by arthritis there might easily occur changes of innervation producing neuralgias and tropho-neurotic alterations secondary in character. Finally, the negative results which he had had in treating polyarthritis deformans after the usual anti-rheumatic method, with iodides, colchicum, etc., and, on the other hand, the very positive results obtained in similar cases by the galvanic treatment of the central nervous system, combined with a generous diet and the persistent administration of cod-liver oil and iron, had led him to believe in the neurotic origin of the disease in many cases. It was through the failure of the old method that he first became convinced of the erroneousness of the conventional opinion of the rheumatic or gouty origin of this formidable malady. Up to the present time no antiphlogos had been made with reference to the condition of the nerve-centers in this disease, and it would be a fit subject for future research to find the changes in the cord, presumably in the anterior horns, which might induce certain forms of arthritis deformans.

With regard to the main features of the disease he had this to say: As a rule it began and developed very slowly, without any other symptoms at first than pains in one or more joints, which came and went either spontaneously or after exertion. Not infrequently the patient complained at this early stage of an unusually tired feeling in the joints. The pains were neuralgic in character, circumscripted or diffused through the limbs. In the peripheral form, the joints of both hands and feet, in the central variety, the hip, knee, and spine, were the parts affected. In the course of time a great deal of stiffness and discomfort were experienced. The joints were enlarged and became unshapeably by the proliferation of hard, oedematous protuberances on the outer surface of the swollen epiphyses, and croaking or cracking in moving or handling them was perceptible to the patient as well as to the physician. The adjacent soft parts, particularly the muscles, showed, in a comparatively early stage of the disease, a degree of atrophy not at all commensurate with their passive condition alone, but much more due to peculiar nutritive changes of neuritic or myotic origin.

In the peripheral form, the disease affected the joints almost symmetrically on both sides; in the central form, the advance was irregular. In one case he had seen it remain stationary in the hip joint for many years, but attacking some joints of the fingers and toes at last. In another case, that of a female patient about thirty-five years of age, the upper part of the body only was affected. He had had a case under observation where nearly all the joints in the body were badly affected when he first saw the patient, who had been a helpless cripple for many months. The disorganization of the shoulder, knee, and particularly the hip, led often to a considerable shortening. In one of his cases, still under observation, the shortening of one lower limb amounted to nearly three inches.

In the spinal vertebrae ankylosis was more quickly developed by the disease than in other parts of the body. One of his patients could neither bend nor turn her head when he first saw her, the entire spine being stiff, but there were no symptoms of compression, or even of remarkable irritation of the cord. The disease was slowly but steadily progressive; while it might remain stationary for a length of time, exacerbations were sure to follow. Fever or other great constitutional disturbances he had not noticed in its course. In a female patient, aged thirty-seven, he had found the urine to have a specific gravity of 1:026, containing some sugar, and phosphates in abundance. Her mother had diabetes, and was a sufferer from arthritis deformans at the same time.

The following cases were selected from his records, as illustrative of the points he wished to bring out:

Case I.—Mrs. M., aged forty-seven, American, no syphilitic or hereditary taint, but a sister is reported to be a sufferer from chronic rheumatism. Married early in life, went on the stage, and, as a somewhat prominent actress, led an active and varied life, experienced many changes of fortune, traveled a good deal, and never hesitated to expose herself to wind and weather, yet always enjoyed good health until two years and a half ago, when, after a premonitory period of worry and depression of spirits, she experienced pains in both wrists and elbows, followed by swelling and distortion. The hands and feet soon followed, and, when he saw her first, February 27, 1883, she had not a joint that did not creak or crack or was not out of shape, except those of the clavicle and the lower jaw. The knees and spinal vertebrae were in the worst condition and the most painful. Standing or walking, even with support, was out of the question. Her urine contained phosphorus, but no albumin. She slept poorly, and her general nutrition was bad; the bowels were irregular. No treatment had so far done any good, but the disease had made rapid and steady progress.

Ordered: B. Propylamin (trimethylamin), f 2 j; Oleossach. citri, f 2 i j; Aque, v j 8 viij M. S. A tablespoonful before each meal.

Ordered also, two pills of sulphate of iron and carbonate of potassium after each meal; good food, and a tablespoonful of cod-liver oil three or four times a day. Galvanism to the spine and the cerebral ganglia of the sympathetic three times a week. The local and general improvement had been so satisfactory that she was now able to get up and around with the help of a cane, and to do light work with her hands. The pain, swelling, and distortion of joints were much less; sleep and nutrition were greatly improved.

Case II.—Mrs. K., aged thirty-four, German, married twice, had had two still-births and two abortions; second husband had syphilis, and died of phthisis. She presented no signs of either disease; no hereditary influences. In 1877–78 she had a severe attack of bronchitis, that troubled her the whole winter, but eventually got well without any apparent damage to the lungs. After some years of trouble, anxiety, want, and exposure, arthritis deformans broke out two years ago, with pain and swelling of the small joints of the hands and feet, soon spreading to one knee, shoulder, and hip. The disease was preceded by severe headaches, from which she suffered yet occasionally, but less violently. Some of the joints presented a gelatinous feel, and several nodules could be felt beneath the integument of her arms. There was no pain on pressure over the sternum, the clavicle, or the tibia. Neither specific nor so-called anti-rheumatic treatment was of any service, but the disease had been very tardy in its progress, and the disfigurement of the joints was not to be compared to those in Case I. She had always been able to walk, though not without pain, and from time to time been confined to her room. Her appetite and general nutrition were not good. The treatment described in Case I was begun in January, 1883, and carried on pretty regularly up to the present time, except as to the application of electricity. The result thus far had been
satisfactory; the progress of the disease had been stopped; and the pain, swelling, and disabilities of locomotion were much less.

Case III.—Mrs. K., aged thirty-five, American; married, multipara. Father in good health, mother suffering from diabetes and arthritis deformans. Patient well built and nourished; living in good circumstances; had been for some years very unhappy in her domestic relations, and had been often deprived of rest and sleep, and otherwise maltreated. After a series of premonitory symptoms, such as hemicrania and neuralgia in the upper extremities, she showed the first symptoms of the disease in the fingers, wrists, and shoulders about a year ago. Her urine contained phosphates (in large amount) and a little sugar. The affection had made no great progress as yet, and the treatment had not been carried out well enough to be of great service, owing to irregular attendance on the part of the patient.

Case IV.—Mrs. H., aged fifty-five; multipara; no hereditary taint; no apparent cause other than a good deal of anxiety and grief; in consequence of the persistent ill-behavior of her only son. The first symptoms appeared in the small joints of the fingers and toes five years ago. So far, she had not experienced any great inconvenience from her affection, but, whenever she took the propyliamine mixture and cod-liver oil for some time, great relief followed as to pain and swelling.

Case V.—Mrs. S., aged sixty-five, German; married, multipara; no hereditary taint, but a good deal of exposure to rheumatic influences in her younger days. The disease first attacked her right hip joint fifteen years ago, which led in the course of time to a shortening of nearly three inches, and now to complete ankylosis. No other joints had suffered until recently, when several small joints of the hands and feet became affected, and she had to take to her bed. Various sorts of treatment were employed to no purpose. For the last three months she had been taking propyliamine, and the compound syrup of the hypophosphites, with the result that she was now able to be about again, and that no other joints had been attacked.

Case VI.—Mr. G., aged sixty, Austrian, clergyman, single, of good constitution and no hereditary taint. He had served as a missionary in his prime, and had traveled extensively in South and Central America. He was, of course, exposed to the severe effects of unwholesome climates, and suffered many hardships besides. He had severe attacks of rheumatism, of which he got well, but eight years ago it settled in his right hip and left knee, and when Dr. Weber first saw him, five years since, he was in constant agony, confined to his bed for many months, and the joints mentioned presented all the characteristics of advanced arthritis deformans. Some of the joints of his hands and feet had also become recently affected. His urine contained albumin in considerable quantity; there were amyloids, the ophthalmoscopic examination showing the affection of the retina often found in Bright's disease and atheroma. By the use of the biddles and the other remedies, he was but little relieved, but two seasons at the Hot Springs of Virginia removed the severe recent affections of the joints, relieved his kidney trouble, and considerably improved his sight. The old affections of his hip and knee remained as before, but ceased to give him much trouble, so that he was able to be about and attend to his clerical duties.

Dr. E. C. WENDT, in opening the discussion, said that he had seen a number of cases of arthritis deformans, mostly in hospital practice, all of which had, under the usual plan of treatment, gone on from bad to worse. He had also seen one of Dr. Weber's cases, in which a marvelous result had been obtained, in a comparatively short time, by an entirely different plan of treatment. He thought the value of Dr. Weber's paper lay mainly in the therapeutic suggestions which it contained. If other observers corroborated the ideas here advanced, a decidedly progressive step would have been taken. He thought it was important to elucidate the causation of the disease: mere symptomatic treatment was quite irrational.

Dr. C. L. DANA remarked that the few cases seen by him had not illustrated the neurasthenic origin of the disease. In New York the disease, he thought, was rarely met with in private practice. He had seen only a few cases in hospital and dispensary service; this was even true in the Marine Hospital for Sailors, where rheumatism abounded. He recollected having seen one aggravated case: the patient was an old woman, some seventy years of age, who had suffered from the disease for sixteen or seventeen years. It began in the vertebral column, and gradually involved the hips, knees, and toes. She was so helpless that, in order to evacuate her bowels, it was necessary to place her in the horizontal position over a pan. She had Bright's disease, and died of apoplexy. On post-mortem examination deposits of urates were found in the joints of the great toes. The patient was poor, and surrounded by all the conditions favorable to the development of the disease. Dr. Dana said he had seen some women of a neurasthenic type—women who had suffered from functional nervous disturbances—who developed a kind of inflammatory swelling of the fingers, so that in one case the hands became almost useless. He did not know but that, later on in life, these cases might develop into arthritis deformans, and, if so, would illustrate the theory advanced in the paper. In considering neurasthenic inflammations of joints, Dr. Dana thought the relation of the trophie nerves to them, if there were any trophic nerves, should not be lost sight of. Never, so far as he knew, had we found any articular disease following from functional nervous trouble. The nervous difficulty must be organic. In no experiment upon animals, except where an organic lesion of the spinal cord had been produced, had we been able to produce arthropathies.

Dr. WENDT did not know that the author's paper contained any evidence that the disease was developed from an organic lesion of the spinal cord. If there had been such disease of the spinal cord, improvement could not have been so rapid. He thought the neurasthenic condition was not the ultimate, but an intervening cause. If we would go back sufficiently far into the history of these cases, he thought we should find that there was at first a disturbance of nutrition, on the basis of which the neurasthenic condition developed.

Dr. F. A. BURHALL wished he could add something to our knowledge of this subject. The disease was one we were continually meeting. It seemed to him to be an arthritis resulting from trophic changes. In two cases which he could now call to mind, these changes resulted from worry. One patient had gouty trouble. There was no uric acid found in the urine of patients suffering from arthritis deformans. As far as remedies were concerned, he knew of only two—arsenic, which was a nerve-tonic, and Eupatorium perfoliatum (bouset).

The PATIENCE felt like adding a word in regard to the practical part of the paper. He had not seen many cases of arthritis deformans in private practice; he could only recall five. It was probable that most cases were seen by the general practitioner. In the first four he had met with unsatisfactory results; but in the last, becoming convinced of the fruitlessness of the anti-rheumatic plan of treatment, he had administered cod-liver oil, iron, and static electrization with great benefit to the patient. He was of the opinion that the disease occurred most frequently in the so-called neurasthenic. It was interesting to note that the first advocate of the neurasthenic origin of the disease was an American, Dr. J. K. Mitchell, the father of Dr. S. Weir Mitchell, now of Philadelphia. At this very early date, 1834, Dr. Mitchell announced it as his theory that acute, subacute, and chronic neurasthenia were diseases of the spinal cord. The neurasthenic theory of the origin of the disease in certain subacute forms was a very attractive one. He was prepared to admit, as an argument in its favor, that the ordinary anti-rheumatic treatment failed to relieve the patient. In the next place, there was a well-understood relationship between the disease in question and well-recognized nervous ailments. We had only to call to mind the arthropathies of the myocilis of traumatic neuritis in certain
PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of October 24, 1883.

The Use of Cactus Grandiflorus in Cardiac Affections.

—The following paper was read by Dr. M. O'Hara:

I was called to see E. O'Hara, aged seventy-four, May 18, 1883. He had bronchitis and some edema of the lungs; his feet were slightly anasarca; there was no kidney difficulty, though he passed but little water; he had a mitral regurgitant murmur; some irregularity of heart's action; occasional intermission; pulse 90; he had arcus serilis and atheromatous arteries, as shown in the radicals and temporals. The diagnosis was dilatation and failing heart, compensation gone by. He was given digitalis, iron, and nux vomica. He became more swollen generally, had orthopnea, and suffered very much, the heart becoming very intermittent on the least effort. The treatment was kept up, with the addition of saline laxatives for extreme costiveness. He was going downward daily, and on June 22d the pulse was very intermittent, and only thirty-four beats to the minute; he was very water-logged in the lungs and over the whole body. I had only seen him at intervals of several days, but still kept up the digitalis, as it is accounted a sure means of restoring compensation to a heart failing from dilatation, after hypertrophy has gone to its maximum. I thought I could be no worse off with any other medicine, or make less speed, and I recalled the fact that I had seen in Flint's "Clinical Medicine," page 223, the statement made that the Cactus grandiflorus, in from three- to five-minim doses, was a valuable heart tonic, and concluded to give it a trial. I ordered it in five-minim doses of the fluid extract (Parke, Davis & Co.) every four hours. In a few days every symptom improved, the dropsy disappeared, and he could lie down at night to sleep. He has been taking the medicine now for five months—the last month fifteen minutes three times daily; he feels quite improved; the dropsy has left him; he has the mitral murmur yet, and some irregularity, but rarely an intermittent pulse. I am satisfied that if I had kept on with digitalis he would have died. Dr. McElroy saw him the day I changed to the cactus, and considered him as a man dying from heart failure, and that he could not live for four hours. He expressed his amazement at seeing him alive and so much improved two weeks later. I also gave the history of the case to Dr. Eskridge, and asked him to visit the patient a month ago, but, unfortunately, have mislaid his note.

On another occasion (in the case of a patient similarly affected) I used digitalis, and it failed me. The Rev. Mr. V. has hypertrophy with dilatation, commencing mitral degeneration, also commencing aortic-valve disease; has pronounced mitral-valve regurgitation; he had violent palpitations, irregularity of pulse, and intermissions; pulse between 40 and 50. Here, I am satisfied, digitalis and convallaria aggravated matters, while the cactus relieved the pain, stimulated the heart, and removed irregularity. The heart never comes up above 50 to the minute, but the horrible feelings of death, with the sudden stoppages, are relieved. In this case there was considerable gastric disturbance, and I assisted with peptic and strychnine, and I wondered why digitalis failed, attributing it in part to its irritating effect on the stomach, thus disturbing the heart reflexly.

In the case of Mrs. Lynch—dilatation with failing heart from age, sixty-five years—I have used nothing else, and it has satisfied me. This person had vertigo, anemia of the brain, dropsy, etc., all due to the failing heart, and the use of cactus inclines me to think it was a good cardiac tonic.

I recall one case of a fatty and dilated heart in which at one period, before an attack of angina pectoris, digitalis had no good effect, yet after that it served very well in the case as a tonic for the heart. Digitalis is a cardiac tonic, acting on the nervous ganglia of the heart, influencing its muscular substance. We shall only find out all its ways by clinical experience. I have tried caffeine for similar heart cases, and sometimes produced no benefit with it. Belladonna and cannabis indica have assisted me in these weakening hearts, especially if I associated these remedies with strychnine. I introduce cactus to the notice of the society, because I have found it to have been little used. Many physicians, if they have like experience to mine, must recall the fact that digitalis at times disappoints them, and I would ask them to try this under those circumstances as a substitute. Of course, I have not had much experience with it, and I would like the result of my experience to be confirmed by that of others.

In nervous affections of the heart I find it very useful; palpitations and neuralgic feelings of soreness about the heart. There are two preparations—Cactus grandiflorus (night-blooming cereus) and Cereus Bonplandii—of apparently the same qualities, the latter of which I have made no use of. The only information I have obtained about these remedies is on a fly-sheet from Parke, Davis & Co., Detroit, Michigan, which refers to its use; physicians, under their own names, speaking of it eulogistically as a complete substitute for digitalis, merely from their clinical experience. This I would not be willing to concede, though we may meet with patients who, from idiosyncrasy or other unexplained cause, can not be benefited by digitalis.

Dr. Fothergill says ("The Heart and its Diseases," p. 287): "The systole is more complete, the chamber is more efficiently emptied, and, consequently, it is not so soon refilled, so that the requirements of the ventricle in diastole correspond to the slower rhythmic discharges, and a slower pulse-rate is established; while the pulse is firmer and less compressible, the arteries are better filled with blood; at times digitalis will notably lower the pulse-rate under other circumstances than those mentioned, illustrating its effects upon the discharging cardiac ganglia. When the pulse-rate falls very markedly under its use, as when it falls below 50, it would be well to substitute belladonna, squill, strychnine, or casca for it." P. 291: "In cases of right-side dilatation, whether from mitral disease or lung changes, it is well to bear in mind the co-existent embarrass-ment of the respiratory centers, and to combine with digitalis, ammonium, nux vomica, or belladonna.

I will merely allude to other remedies stated to possess an allied action to digitalis—the Cereus Bonplandii, introduced by Parke, Davis & Co.; Lander Brunton has found casca, the ordeal poison of Africa, to have a nearly similar action; Professor Frazer has used the Strophanthus hispidus; M. Brandoun found the dajask, or arrow-poison of Borneo, to kill with the heart firmly contracted in systole. These I am not familiar with in practice, but often have used the Scilla maritima, which is an excellent diuretic in cases of feeble pulse. The same can be said of scoparion, or broom. Caffeine, though highly spoken of, I have not found to merit the laudation accorded it as a cardiac tonic, though I have frequently found benefit in substituting belladonna when digitalis seemed, from unknown reasons, to fail me.

Convallaria majalis has been written of so recently in the Pennsylvania State "Transactions" by our member, Dr. Bruen, that I merely refer to that article.

My limited experience goes to show:
1. That cactus is a pure cardiac tonic, whether for functional or organic disturbances, especially in cases of mitral regurgitant disease.
2. Convallaria, though not of service in cases accompanying natrual regurgitation, appears specially, from Dr. Brun's paper, to be a supplement to digitals, not replacing it; specially serviceable in backward distension of the lungs, from natural obstruction, and is a fine tonic for nervous and functional disturbance of the heart.

3. Belladonna and strychnine will frequently serve to take the place of digitals.

4. Caffeine citrate has been found to be of no effect in my experience for heart affections, functional or organic.

OBSTETRICS AND GYN.ECOLOGY.

By ANDREW F. CURRIER, M.D.

The Condition of the Uterine Mucous Membrane during Menstruation.—Wyder ("Ztschr. f. Geb. u. Gyn.," ix, 1), in an interesting article, contributes the results of his labors in this field, together with a résumé of the by no means abundant literature of the subject. Among his co-workers, Moricke and de Sinéty have reached almost identical conclusions, though working at the same time, without knowledge of each other. The writings of Kundrat, Engelmann, Williams, and Leopold, especially the last mentioned, also evince careful investigation of the subject. All of these writers admit that more work is yet required in order to a thorough understanding of this matter. All, excepting Moricke and Sinéty, agree that during menstruation the uterine mucous membrane is stripped of its epithelium, and is converted into the condition of a wound. Williams asserts that this stripping involves the entire mucous membrane; the other authors claim that only its superficial layers are lost.

In the matter of the fatty degeneration of the mucous menstruallis, Williams, Kundrat, and Engelmann consider that it is the factor, above all others, which leads to hemorrhage; Leopold, on the other hand, considers that it occurs in consequence of the hemorrhage, which is the primary element, which is shown by the widely dilated capillaries, and the relatively poor supply of veins in the mucous membrane at the menstrual period. That portion of the mucous membrane which is not removed is in a state of cell-hyperplasia; hence we are able to understand how the lost tissue is restored. According to Kundrat and Engelmann, the renewed membrane is analogous to the decidua, and in it, according to the author (Wyder), are many interglandular cells, some of which contain nuclei. Moricke's views concerning the loss of epithelium during menstruation are stated in the following propositions: 1. The mucous membrane does not disappear, either wholly or in part, and it retains its cylindrical epithelium. 2. Interglandular cells are neither increased in number nor enlarged, and fatty degeneration occurs only to a limited extent. 3. The vessels are greatly dilated, and extravasations into the upper layers of the mucous membrane occur. The foregoing statements are based upon investigations made upon living subjects at different periods of menstruation. Sinéty observes that the distinguishing characteristic of the menstrual fluid is the presence of white corpuscles or their embryonal elements. The author's conclusions from his own investigations, and an analysis of the published cases of Leopold and Williams, also from a comparison with the propositions of Moricke and de Sinéty, are as follows: 1. The superficial layers of the uterine mucous membrane are thrown off during menstruation, and, when examined, are found to consist of entire cells, broken-down cells, and detritus; and, in some cases, of shreds of mucous similar to those which are found in membranous dysmenorrhea. 2. The hemorrhage of menstruation is the cause of this loss of substance. The parts which undergo fatty degeneration do so as a result of the hemorrhage. 3. Small cells in abundance are found in the superficial and middle layers of the mucous membrane which remains, but the latter bears no resemblance to the decidua of pregnancy. In the deepest layers there is a cellular hyperplasia of the interglandular tissue, the object of which evidently is to effect a restoration of the lost tissue. 4. The superficial epithelium, which may have remained after the current of the menstrual blood has swept away the remainder, undergoes fatty degeneration.

Internal Division of the Cervix Uteri for Dysmenorrhea.—Dr. W. Macie Campbell ("Liverpool Medico-Chir. Jour.," Jan., 1883) gives a brief account of three such operations. In the first case, in addition to the dysmenorrhea, were vaginitis, dyspareunia, and sterility, the cervix being conical and affected with catarrhal inflammation. The cervix was divided bilaterally. In two months the patient reported that she was perfectly well, and that her periods were painless. In the second case the dysmenorrhea was of an aggravated character, and was also associated with sterility. The succeeding period was painless, but exposure to wet at the following period brought a recurrence of the pain. The operation in the third case, or possibly the use of the uterine stem (which was also used in the two other cases), caused peritonitis, not of a severe type, however. No relief to dysmenorrhoea followed. Only the first case, then, was successfully treated by this operation, from which the author concludes that this one alone of the three was mechanical dysmenorrhea, and required the operation. His preference in future for the treatment of this disease will be gradual dilatation.

The Vomiting of Pregnancy.—Horwitz ("Ztschr. f. Geb. u. Gyn.," ix, 1) objects to the unrestricted use of the phrase uncontrolable vomiting in all cases of pregnancy in which vomiting occurs. The phrase of Guéniot, pernicious vomiting in pregnant women (vomitus gravidarium perniciosus), is more appropriate and more precise. The following propositions are advanced: 1. The uncontrollable vomiting of pregnancy usually begins between the tenth and eleventh weeks. 2. There are, generally, premonitory symptoms. 3. Nausea and other disturbances of the digestive apparatus constitute such premonitory symptoms. 4. Nausea often begins in the third or fourth week of pregnancy. 5. The duration of the vomiting is, as a rule, inversely as that of the nausea; the longer the latter, the shorter the former. 6. The more unbearable the nausea, the shorter the duration of the period of vomiting. 7. Ordinarily, the vomiting which occurs in pregnancy is painless, and unlike which characterizes gastritis. The clinical symptoms persist (1) to the period in which the phenomena are beginning to develop, but are not yet pronounced; (2) to the period in which they are established and threatening. Other marked symptoms, in addition to the vomiting, are loss of appetite, and even repugnance to food, salivation, and hyperosmia. The latter is a curious symptom, the patient being excessively sensitive to odors, real or imaginary, about her own person, and at other times to odors in her surroundings. This seems to be one of the causes of nausea; it disappears when the vomiting period supervenes. Obstinate and uncontrollable vomiting during pregnancy is most common in France, less common in England, and rare in Germany. Those who have suffered from uterine disease are most likely to be the subjects of uncontrollable vomiting when in the pregnant state. The author can suggest no more plausible theory of causation than the reflex irritation theory. As to prognosis, that will depend upon the duration of the mischief, and the epoch of pregnancy in which it appeared. It is bad
Reports on the Progress of Medicine. 561

Nov. 17, 1883.

According as the vomiting begins near the beginning of pregnancy, Joubin gives the mortality in this disease—that is, in the obstinate form—as forty-four per cent. In regard to treatment, scarcely any new suggestions are made. Artificial abortion becomes a necessity when other means have failed. Transfusion of blood, in almost any supposable case, is not to be considered.

A New Remedy for the Vomiting of Pregnancy.—Dr. T. C. Wallace ("Med. and Surg. Reporter," Feb. 17, 1883) reports the use of a substance for the treatment of this condition which is new to materia medica. It is ordinary poppyseed, salted to taste. Lest a smile of irreverence should appear, the author states that he has had four years' experience with it, and has "always found it beneficial, and generally a sufficient remedy." A case is narrated in which every conceivable remedy for this condition had been tried without success, but was happily relieved by the use of poppyseed.

Occipito-posterior Positions.—Charles R. Thompson, M. R. C. S. ("Brit. Med. Jour." July 7, 1883), contributes the following useful hints with reference to this undesirable form of presentation. He first calls attention to the mechanism of labor in such cases, the forehead being pressed against the pubic arch, and the tendency of the vis a tergo being to force forehead and face forward, rather than to force the occiput onward, and cause it to sweep along the hollow of the sacrum. This condition is apt to obtain, unless rotation should occur, and cause the forehead to occupy the hollow of the sacrum. To remedy the faulty position, the occiput should be pulled down, which will be accompanied by recession of the forehead, and progress will result. The author has found that the wholebone fillet offers the best means for accomplishing this end, his plan of operation, after ascertaining the exact location of the head, being to pass the index and middle fingers of the left hand into the vagina until they reach the posterior fontanelle, and, if possible, are pressed against the occipital bone. The fillet is then passed along the left palm and fingers until it reaches the head, in a compressed condition. It is then allowed to expand, and caused to embrace the occiput. Traction is then made during the pains, the fingers of the left hand remaining in the vagina to guide the head in its progress. Rotation may then occur spontaneously, or, if not, labor pains will be excited by the pressure of the occiput against the posterior vaginal wall, and the labor will probably be soon terminated. Six cases are narrated in which the author adopted this method with desirable results.

A Spina Bifida Presentation is reported by Charles Rudderock, M. R. C. S. E. ("Brit. Med. Jour." May 12, 1883), the child being the patient's fourth. No abnormality had attended previous confinements. Examination naturally suggested a face presentation, the orbits, nose, and mouth being successively, as was supposed, identified. The hand and hip being next discovered, the conclusion was reached that the lumbar region was presenting. Turning was decided upon and effected. A dead female child was delivered with a hydrocephalus head, and a large spina bifida in the middle of the lumbar region. The mother made a good recovery.

The Use of Anaesthetics During Labor.—Dr. Thomas D. Savill ("Brit. Med. Jour." May 12, 1883) recently read a paper with the foregoing title before one of the London societies. His first point in favor of anaesthetics was that they relieve pain and thus prevent the loss of vital force at a very important period of time. Their relaxing power, too, not only overcomes rigidity of the tissues, but tends to obviate convulsions. The chief objections to their use in normal labor are, that they are liable to weaken the uterine contractions, and may induce post-partum hemorrhage. Their value in abnormal labor is beyond estimation, especially in those cases in which operative procedure is required. As to the choice of anaesthetics, the author favors chloroform, in almost all cases, to be used until partial or complete unconsciousness, according to circumstances, is reached. The reasons for its use and the caution to be observed are those which are generally recognized as suitable. His advice to give a full dose of ergot in warm water, when the head reaches the perineum, will not be accepted by every one as good doctrine.

The Treatment of Post-partum Hemorrhage.—Dr. Percy Boulton ("Med. Times and Gaz.," May 5, 1883) presented a paper with the foregoing title to the Harvian Society, March 1, 1883. He considered that true post-partum hemorrhage was largely preventable, especially in those cases in which it so often occurs, in which parturition is allowed to drag on for hours and days after it should have been terminated, and in which uterine inertia has supervened. For the treatment of the accident when one is confronted by it, the author recommends the same useful means which are recognized the world over. As to the use of the liquor ferri perchloridet in those cases in which it is required, he thinks it is better to inject it with a syringe rather than to apply it upon a sponge, or in any other uncertain manner. Auto-transfusion is the term which he gives to the combined act of raising the foot of the bed and bandaging the extremities. His apparatus for transfusion is rather unique, and consists of a piece of rubber tubing of suitable length and lumen, in either end of which is fitted a glass cannula, and at a short distance from the latter a spring clamp. This he uses for direct transfusion, after properly displacing the air in the tube with a saline solution.

Inversion of the Uterus Followed by Spontaneous Amputation.—Dr. R. Milne Murray ("Edinburgh Med. Jour," April, 1883) reported this case to the Edinburgh Obstetrical Society, the facts having been stated to him by the gentleman in whose practice the case occurred. The patient was forty years of age, and this was her seventh pregnancy. All previous ones had been normal, and there was no fault, so far as could be ascertained, in the pelvic organs. The labor, in this instance, was normally ended, and the placenta was expelled spontaneously. Twenty-four hours later the uterus was found to be inverted. It was replaced without difficulty, but was again found to be inverted on the following day. All efforts to keep it in position were unavailing, and on the fourth day constitutional disturbance was noticed. This gradually became worse in spite of all possible attentions. On the thirteenth night, post partum, the uterus sloughed off, without hemorrhage. A long and severe illness followed, but the patient eventually recovered.

Observations on the Bladder During the Early Pelvic Pericardium.—Dr. J. Halliday Croom ("Edinburgh Med. Jour," April, 1883) read an article from this text before the Edinburgh Obstetrical Society, January 10, 1883. He observed that immediately after the third stage of labor, and during the early puerperium, the bladder exerts an important influence on the uterus, especially as regards its position. The latter organ lies lower in the pelvis immediately after labor than it does a few hours later. It is usually in a central position, though it may be deflected to either side. It offers no obstacle to the distension of the bladder, hence the latter may easily be felt at this period, when distended, through the anterior vaginal wall. The effect of this distension is to displace the uterus upward more by a straightening of the organ, however, than by any actual forcing of it upward, the supposition being that it had sagged forward, as well as descended, after parturition. The mesial position of the uterus which is found in so large a number of cases presupposes a dorsal decubitus on the part of the patient, as well as an empty condition of the bladder and rectum; deflection occurs when these conditions are not present, and deflection to the right is more common than to the left. The greater the quantity of urine in the bladder, the greater the deflection, as a rule,
It is also to be borne in mind that the female bladder distends asymmetrically. As a summary in respect to right and left deflections of the uterus, the former is due: to a previously existing right lateral deviation of that organ during pregnancy, to a distended rectum, to the accident of position. The latter is due to the filling of the bladder, which, on account of asymmetry, expands more to the right side, or to the left lateral decubitus of the individual. These changes are most noticeable in the early days of the puerperium, for, as this advances, the uterus becomes smaller and firmer, and so less susceptible to the action of such a force as is exerted by the distending bladder. (To be concluded.)

MISCELLANY.

THERAPEUTICAL NOTES.—Spiritus Aetheris Nitrosi.—Dr. D. J. Leech, professor of materia medica and therapeutics in Victoria University, in a recent paper (“Practitioner,” October, 1883), expresses the opinion that the very general lack of confidence in the efficacy of spirits aethers nitrosi arises from ignorance of the physiological and therapeutic action of this drug. His experiments have convinced him that its effects are more distinct and less transient than they are generally supposed to be. Its properties depend on the nitrous ether (nitrite of ethyl) it contains (from three to four per cent. when pure). The action of nitrite of ethyl is analogous to that of nitrite of amyl, of nitroglycerin, and of the nitrates of the alkaline metals, but, contrary to what might have been expected, the influence of the drug upon the circulation, in moderate doses, is of considerable duration.” One hundred minims of spirits aetheris nitrosi specially produced, in a healthy subject, a marked fall in arterial tension lasting two or three hours. Doses of twenty-five or fifty minims produced a similar effect, though less marked and less enduring. The fall in tension was always accompanied by increased frequency of the heart-beat. The percussion-wave in the sphygmographic tracing was heightened. Experiment proved that the action of the sweet spirit of nitre could not be attributed to the rectified spirit it contained in large proportion. There was generally a notable absence of subjective symptoms, even when the fall in arterial tension was very considerable. However, large doses may cause slight throbbing, giddiness, faintness, or depression. The acceleration of the pulse is not so great as that produced by nitrite of amyl or by nitroglycerin; small doses do not usually increase the frequency of the pulse-rate very much.

The therapeutic rôle of spirits aetheris nitrosi is mainly due to its influence on the circulation. It reduces arterial tension, in part, at least, by its power of dilating the arterioles in certain areas. Thus, probably, it acts as a diuretic. “It seems probable that any agent which increases the rapidity of the blood-flow through the Malpighian glomeruli is capable of increasing the secretion of water, and that both those agents which increase arterial tension and those which decrease it may, under different conditions of the circulation, in this way produce diuresis. Sweet spirit of nitre will probably not act as a diuretic unless decrease of tension is necessary for diuresis. This view accounts for the frequency with which it disappoints the practitioner who employs it to increase the flow of urine. In cardiac dropsy, for instance, the indications for spirits aetheris nitrosi will rarely be present, and it is in this affection that its failure as a diuretic has been specially noted. On the other hand, it usually acts satisfactorily in elderly people in whom tissue degeneration has produced increased arterial tension. The short diuretic effect of sweet spirit of nitre, even when it causes increased urinary secretion, as compared with the effect of digitalis, is explained by its comparatively short influence on the circulation. The diaphoretic action of nitrous ether, like its diuretic action, is due to its effect on the circulation. The reason the dilatation of the cutaneous vessels to which it gives rise is not always followed by perspiration is that such dilatation is but one factor in the causation of diaphoresis.

It is clear that it may cause a tense, small pulse to become not only quicker, but also fuller and stronger to the feel. Moreover, the heart’s action under its influence may become perceptible to the patient. These facts account for the stimulant action which it has been supposed to exert on the heart. The febrifuge properties for which it is often given are due, partially at least, to the dilatation of the cutaneous vessels it produces, and to the consequent exposure of a larger amount of blood to the air. However, they may be due also, in part, to some direct influence of the drug on the tissues; for Wood has noticed that the fall in temperature which in animals follows the administration of nitrite of amyl is accompanied by diminished excetration of carbonic dioxide.

Nitrate of ethyl, the essential constituent of sweet spirit of niter, has been found effectual in averting attacks of angina pectoris. And, while spirits aetheris nitrosi will probably never take the place of nitrite of amyl or nitro-glycerin throughout the whole spheres of their actions, yet it will doubtless prove beneficial in many conditions in which relief is afforded by the latter agents. “May it not be that our failures with it have arisen partly from the use of an impure spirit, partly from the want of knowledge as to the physiological effects on which its therapeutic uses depend; and that the use of the genuine drug in proper cases, may only show that the popular belief in the efficacy of sweet spirit of niter is founded on fact?”

An Acid Solution of the Hypophosphites.—Dr. George S. Gerhard, of Ardmore, Pa., recommends (“Philadelphia Medical Times,” November 3, 1883) an acid solution of the hypophosphites, which has been successfully prepared by his pharmacist at his suggestion. The salts are dissolved in water acidulated with hypo-phosphorous acid. In the strups precipitation is prevented by the sugar. “The addition of a definite amount of hypophosphorous acid prevents the precipitation of at least two of the salts (those of iron and manganese).” The solution recommended is clear, slightly fluorescent, and pleasantly acid. It exerts a decided tonic and stimulant action. It increases the desire for food, and agrees with the most sensitive stomach, while the strups, from their excessive sweetness, may only decrease the appetite, but often impair digestion. The formula for the solution is as follows:

- Calcii hypophosph. 1
- Potassii " 1
- Solii " 1
- Quinina " 1
- Mangani " 1
- Ferri " 1
- Strychnina " 1
- Glycerini 1
- Liq. acidi hyposulph. 1
- Aq. ad. f. 3 j

THE LATE SURGEON-GENERAL CRAN

THE FOLLOWING CIRCULAR HAS BEEN ISSUED FROM THE SURGEON-GENERAL’S OFFICE:

WAR DEPARTMENT,

Washington, D. C. October 24, 1883.

With profound sorrow, the death of Brigadier-General Charles Henry Crane, Surgeon-General United States Army, which occurred at his residence in Washington, D. C., October 10, 1883, is announced to the officers of the Medical Department of the Army.

General Crane, son of the late Colonel I. B. Crane, 1st United States Artillery, was born at Newport, R. I., July 19, 1825, and received his early education at Maple Grove Academy, Middletown, Conn. He entered Yale College in 1840, graduating in 1844, with the degree of Bachelor of Arts. The degree of Master of Arts was conferred upon him by the same institution in 1847.

He graduated in medicine at the Medical Department of Harvard University in August, 1847.

Having been approved by an Army Medical Examining Board, December 11, 1847, as a candidate for the position of Assistant Surgeon, United States Army, he was immediately placed under contract as an Acting Assistant Surgeon, and accompanied a detachment of troops to Mexico, arriving at “Camp Washington,” near Vera Cruz, February 20, 1848. He was commissioned Assistant Surgeon, United States Army, on February 14, 1848. From February 20 to July, 1848, he served with the “Army of Invasion” in Mexico.
On returning from Mexico, early in August, 1848, he reported for duty at Fort Columbus, New York Harbor, and was assigned to duty with the 2d United States Artillery at Fort Monroe, Va. He was then ordered to Florida with troops, arriving at Fort Pickens, Pensacola, Fla., November 10, 1848. From this date until August 10, 1851, he served at Key West Barracks, St. Joseph's Island, Forts Pickens, Brooke, Fraser, Casey, and Myers, and with expeditionary forces in the field. On being relieved from duty in Florida, and at the termination of a leave of absence, he reported for duty December 18, 1851, and on January 13, 1852, sailed from New York in the steamer Falcon, with recruits for California. He arrived at Benicia, Cal., February, 28, 1852, and was assigned to temporary duty at Benicia Barracks. From June 16 until September 1, 1852, he was engaged in field service against hostile Indians near Merced River, Cal. From September 23 until November 10, 1852, he was again in the field with an expedition in the Sacramento Valley, Cal. November 10, 1852, he arrived at Fort Jones, Cal., where he remained on duty until July 15, 1853.

From October 31, 1853, until March, 1856, he was on duty at Fort Lane, Oregon. During these years he was actively engaged in post duty and with military expeditions against Indians, prominent among which was that against the Rogue River Indians in 1856, where he rendered distinguished service.

On August 7, 1856, he was ordered to Fort Yarnell, Oregon, where he served until relieved from duty on the Pacific Coast in December, 1856.

Reporting for duty in New York, he served for a short time with the 2d United States Artillery. From May 1, 1857, until September 20, 1859, he was one of the members of an Army Medical Examining Board convened to meet in New York City. Being relieved from this duty, he remained in New York, acting at times as Medical Purveyor.

September 20, 1859, General Crane accompanied Lieutenant-General Scott to San Juan Island, on his diplomatic visit, returning to New York December 12, 1859, and continuing on duty as Attending Surgeon at Headquarters of the Army, and on special duty until February 28, 1862.

He was promoted Major and Surgeon May 21, 1861.

On February 28, 1862, he was assigned to duty as Medical Director, Department of Key West, Fla. On June 30, 1862, he was transferred to Hilton Head, S. C., and assigned to duty as Medical Director, Department of the South. July 31 to August 16, 1863, he is reported as suffering at Washington, D. C., and on duty connected with Prisoners of War.

September, 1863, he was placed on duty in the Surgeon-General's Office, Washington, D. C. July 28, 1866, he was appointed Assistant Surgeon-General, U. S. Army, with the rank of Colonel, and, upon the retirement of General Barnes, was appointed Surgeon-General, July 3, 1882.

March 13, 1865, General Crane received the brevets of Lieutenant-Colonel, Colonel, and Brigadier-General, for faithful and meritorious services during the War of the Rebellion.

In the death of Surgeon-General Crane the Medical Department of the Army sustains a serious loss. Still in the vigor of life, and with a remarkable record of several years of active service in the position to which he had been recently promoted, it has pleased an inscrutable wisdom to remove him from our midst.

His record, honorable and spotless, lives after him; a source of pride and satisfaction to his friends, a model worthy of imitation by all.

The larger portion of his official life was engaged in administrative duty, for which he had always manifested a peculiar fitness.

Selected to assist in the arduous and important duties devolving upon this office during the latter years of the War of the Rebellion, his sound judgment, delicate sense of justice and right, deliberate action, and firm decision, soon won for him an enviable reputation, and materially assisted in raising the Medical Corps of the Army to the high degree of discipline and efficiency which has characterized it in the past and present.

In the literary and scientific work of the office he manifested uninter-
MISCELLANY.

Surgeon then, fails tinging mouth, the been mulation probability though two caused months, meniscus We Dislocation removed, which that in the removal of considerable portions of the upper jaw it has sometimes been found necessary to perform tracheotomy on account of the accumulation of blood, but by the use of the prone position this will be unnecessary, as the blood readily flows from the mouth. Professor Tiffany recommends that the head should be slightly raised. We have found that it is better to allow the head to be in a line with, or even sometimes a little lower than the body, the removal of the blood being effected by turning the head to one side or the other. In operations in dental surgery, performed in this manner, we have never known to cause any embarrassment whatever.—Independent Practitioner.

DISLOCATION OF THE SEMILUNAR CARTILAGE OF THE KNEE JOINT.—Although this injury is described in all surgical text-books, we yet believe it is one that is not frequently overlooked, especially on its first occurrence. A gentleman falls down, and is picked up complaining of severe pain in the knee, with partial or complete immobility of the joint, which speedily becomes swollen. There is great likelihood in these circumstances the diagnosis of "severe sprain" will be made, and the real condition remain unnoticed. The failure to replace the dislocated cartilage at the time not only entails much suffering and interference with the function of the joint, but it very greatly lessens the probability of a complete recovery ever being accomplished. The cartilage may be reduced, but it fails to become firmly fixed in its place, and ever afterward there is a liability for it to slip out again during the free movements of the joint. When this happens, acute pain, possibly a fall as well, and temporary lameness are occasioned. There is therefore every reason why the surgeon should endeavor to recognize this particular injury on its first occurrence, and having recognized it to treat it properly. The accident happens during some sudden wrench to the joint, not necessarily severe; immediately severe thickening pain arises, and the limb is fixed in the flexed position, although passive movement is possible. Synovitis quickly ensues. If the cartilage is displaced from between the bones, or if it forms a projection just over the interval, between the femur and tibia; but in some instances it is dislocated inward, so as to lie between the two condyles of the femur, and then is quite beyond reach. In such cases the diagnosis must rest alone upon the cause of the accident—some wrench or sudden movement—the acute pain, and the fixity of the joint in the flexed position. The symptoms are more severe than those caused by a simple sprain of the joint from such an amount of violence, while, on the other hand, the slipping of a loose cartilage between the bones causes still more acute suffering, and the body itself can be felt at times. The first thing to do is to replace the cartilage by extreme extension immediately following upon full flexion of the joint. In some cases the cartilage slips into place with a distinct snap, and in all cases the power of movement is at once restored. It is then important upon the patient to wear a firm support to the knee for some months, which shall render impossible such a wrench of the joint as shall displace the cartilage, and if this is persevered in the cartilage again becomes adherent to the tibia. It is believed that the internal meniscus is more frequently displaced than the outer.—Iarret.

USE OF THE RECTAL LEEVER.—On October 9, 1883, Mr. Cowell amputated through the left hip-joint of a man, in the Westminster Hospital, for old-standing disease of that articulation. Mr. Richard Davy con-

A CLINICAL LECTURE IN

GYNECOLOGY,

DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

BY WILLIAM GOODELL, M. D.,

PROFESSOR OF GYNECOLOGY.

Haemorrhage after the Operation for Laceration of the Cervix Uteri.—Remarks on the Use of Pessaries.—Vaginal Injections.—Amenorrhoea as a Result of Metrorrhagia.

Gentlemen: Owing to the cold weather, but few patients have presented themselves at our clinic to-day. I shall, therefore, be unable to show you any operations, but, on the other hand, I shall bring before you a few cases and make some practical remarks on them, which may, perhaps, be of more value to you.

Our first patient is a young woman upon whom I operated some time ago for laceration of the cervix. The laceration was bilateral, on one side reaching down to the vaginal junction. Let me say here that when you come to denude a laceration which extends to the vaginal junction, you are likely to cut the circumflex artery and get a pretty free haemorrhage. What is to be done under such circumstances? The tissue is erectile, and so firm that the vessel cannot readily be ligated; and, indeed, it would not do to tie the vessel, because the ligature would interfere with union. As soon as the haemorrhage occurs, take a sponge and firmly press it on the bleeding part. Then with a needle pass a stitch down deep below the vessel. Traction on the ends of the wire will usually control the bleeding; but, if it does not, the stitch must be drawn firmly, and secured by slipping a shot down and clamping it. When the other stitches are introduced, it is well to pass another wire so as to include the vessel. I have had secondary haemorrhage but twice after this operation. In one of the cases the womb was adherent and held high up by inflammatory adhesions, which rendered the operation quite difficult. In this instance the bleeding was readily controlled by the injection of a hot solution of alum. The second case occurred about a month ago. On the second day after the operation a severe haemorrhage set in. I was sent for by the nurse, and found the patient had lost and was losing a great deal of blood. I at once proceeded to plug the vagina, but I did not tampon the vagina in the ordinary way, for, as the laceration was bilateral with a posterior and anterior lip, were a sponge pushed directly against the cervix it might spread apart the lips, or a clot might form behind the sponge and gradually separate the lips, thus making the operation a failure. In order to avoid these accidents, I took two sponges, and, after dipping them in vinegar, passed one into the posterior cul-de-sac of the vagina, and the other into the anterior cul-de-sac, thus pressing the lips of the cervix together. The vinegar was used not for its haemostatic effect, for this would, under the circumstances, be very slight, but because it is a good deodorant, and was the only one available at the time. Over the sponges I introduced one of my patient's handkerchiefs, packing it in little by little, and leaving an end, or tail, protruding, in order to facilitate its removal. By the way, an ordinary roller-bandage, when unravelled, makes an excellent tampon. It may be firmly packed into the vagina and one end left projecting from the vulva. By drawing on this tail, the tampon is readily removed. At the end of twenty-four hours I removed the handkerchief, and in forty-eight hours, as there was no bleeding, I removed the sponges. No more haemorrhage took place, and the union was perfect.

In the patient now before you there was, as the result of the operation, a slight cellulitis and perhaps a little peritonitis. It was not sufficient to cause any marked elevation of temperature, but rendered the womb somewhat tender. After the operation I had to contend with a badly retroflexed and retroverted womb, which was exceedingly tender. The difficulty was to keep this tender womb in its proper position by the use of a pessary. If in such a case you introduce a hard pessary, it causes so much pain that it has to be removed, and the woman is so thoroughly demoralized that you will find it a difficult matter to get her to wear another. The proper plan is first to obtund the sensitiveness of the womb and vagina. This may be done in a variety of ways. If the vagina is of sufficient size to admit a pessary long enough to span the angle of flexure and to keep the womb up, your course is clear. The patient should be put to bed, vaginal suppositories, containing sulphate of morphine and extract of belladonna should be used, and large quantities of hot water should be injected. The mistake that is usually made in the use of hot-water injections is that too small a quantity is employed. A quart of water will do more harm than good. As I sometimes illustrate it: If you were going to a party and wished to get on a pair of tight kid gloves, you would not wash your hands in hot water; for that would make them swell. But should you dabble them in hot water for fifteen minutes, you would shrivel up like a washerwoman's hands, and you could, with a little trouble, get on the gloves. So, if you inject a small quantity of water into the vagina, blood is invited to the part and there is an increased congestion. If, however, a large amount be injected, the secondary effect of the hot water is obtained. It then causes contraction of all the tissues and the capillaries, thus lessening the amount of blood in the womb. The quantity used each time should not be less than one or two gallons. It is far better to inject the water from a syringe than to use the douche, for when it is projected forcibly it makes a more marked impression. No woman can herself use a syringe for fifteen or twenty minutes in the position which it is necessary that she should maintain. It must be done by an assistant; but, if she can not afford a nurse, as unfortunately happens too often in those cases that come to the hospital, she will have to use the douche. This is called a fountain reservoir. It consists of a tin pail holding two or three gallons, with a cock on one side, to which is attached a rubber tube, at the extremity of which there is a nozzle. This
nozzle should not be made of metal, for, as the water has to be at a temperature of from 110° to 120°, the heat is conducted by the metal to the sensitive vulva, giving rise to the sensation of being scorched. As you have been told before, I consider the nerves of the vulva to be more sensitive than those of any other portion of the body, not even excepting those of the eye. The nozzle should, therefore, be of rubber. It should have no terminal opening, but its sides should be perforated by a number of holes which will direct the water forward. A few words in regard to the administration of hot-water injections. There can now be bought in this city an arrangement which is called a douche-bath, and which greatly facilitates the administration of hot vaginal injections. This douche-pan is on the principle of the shovel bed-pan, but larger. There is a ledge on which the buttocks rest, and in front there is a little reservoir, from the side of which projects a nozzle. To this nozzle is attached a rubber tube, which carries the liquid, as fast as it flows from the vagina, into a vessel beneath the bed. Before this was introduced, I had the patient brought to the edge of the bed with her feet supported on chairs and her hips well elevated by a pillow. Over the pillow was placed a large rubber cloth, so arranged as to form a gutter, to carry the liquid into a vessel placed on the floor. In this way a large amount of water could be easily injected, but it was a cumbersome way, and I much prefer the douche-pan, which simplifies matters.

There is a word of caution to be given in this connection. Sometimes, as a result of laceration of the cervix or on account of other causes, the os may be so patulous as to admit the nozzle of the syringe, and, if, like the old-fashioned nozzles, it has a terminal orifice, the water will be projected directly into the cavity of the womb. The womb immediately resents the presence of the water and forcibly contracts; but, as the nozzle completely occludes the os, the water is forced through the Fallopian tubes into the peritoneal cavity, causing inflammation. I have seen a number of instances of uterine colic from this cause, and every year there are reported cases in which death has followed the injection of simple water into the womb. I must acknowledge that I do not clearly see why this accident should be followed by such serious results. You should always examine the syringe before it is used, and, if there is a terminal opening, close it either by a little plug of wood, or by tapping around the hole with a small hammer.

The water may be medicated with various remedies. Laudanum will do much to obtund the sensitiveness. One or two ounces may be added to the water. I am not in the habit of using this, for the laudanum is so diluted that it does not make the same impression as a suppository, which will remain in the vagina for hours and be absorbed gradually. I have often seen patients go to sleep after the use of a morphine suppository in the vagina. In using belladonna, I never employ at first more than one grain of the extract, but, if necessary, gradually increase it to two grains. There is a great deal of idiosyncrasy in regard to belladonna. In some persons one eighth of a grain by the mouth will produce toxic symptoms. I have heard a clergyman, to whom I had given one half of a grain of the extract, talk the most unmitigated nonsense for some hours, alarming his family and the whole neighborhood.

Ammonium chloride may with advantage be added to the water. If there is any offensive discharge, chlorate of potassium is of service. I, however, prefer the chloride of ammonium to any other remedy, adding one ounce of the salt to each injection.

Having by these means obtund the sensibility, and if the vagina is long enough, you introduce a pessary which will raise the fundus of the womb. If you can relieve the dislocation, the tenderness will soon disappear. This tenderness is due to two conditions. In the first place, the womb is turned upside down; it is standing on its head, as it were; the blood-vessels then become enlarged and turgid, and, consequently, the womb is tender. In the second place, an ovary often descends with the womb as it turns over. If the womb be kept in its proper position for a few hours, this congestion lessens, and the longer the pessary remains the less tender the womb becomes. After two or three days the patient may be allowed to get out of bed.

When, however, you have to deal with a tender womb and a short vagina, all your skill in the adaptation of pessaries will be needed. I know of nothing more trying to patient and physician than the replacement of a retroverted womb in an unmarried girl with a short vagina. I have always succeeded, but it requires patience on both sides. The proper plan is to put the patient to bed, and obtund the sensibility by the use of hot water, medicated or not, and by suppositories. Having done this, put in a pessary as long as can be borne; in a few days put in a longer one, and so on increasing their size until the vagina is sufficiently stretched to admit a pessary that will replace the womb.

A word in regard to the action of pessaries. We can easily understand why there should be a diversity of opinion on purely theoretical questions: but, when the question is one of sheer mechanical action, we should expect that all would think alike; such, however, is not the case in reference to the action of pessaries in posterior displacements. Some, and indeed the majority of authorities, contend that the way in which a pessary does good is not by pressing upon the fundus or the corpus, but by elongating the vagina, which draws the cervix upward and backward, and, as a consequence, tilts the fundus forward. I am willing to grant that this is the usual action of a pessary; but that it is not its only action I have had digital proof. Hence, I contend that the pessary sometimes undoubtedly impinges upon the body of the womb through the vagina, thus pushing it forward and straightening it. If this were not so, there would be no good derived from a Hodge pessary in retroflexion. But, as I have frequently told you, this pessary will straighten a retroflexed womb when it is long enough to span the angle of flexion. It then does not press on the fundus, but on the body of the womb beyond the bend. If it is not long enough, the womb will ride the pessary and straddle it, thereby increasing the flexion. Last week I had, as I just said, digital proof of this. I at that time performed oophorectomy in a case in which perityphlitis had been followed by abscess. The resulting cellulitis had so im-
prisoned the right ovary that it could not move, and, consequently, great pain was caused whenever the cecum and colon were loaded. Various methods of treatment were tried, but, all failing, I determined to extirpate the offending organ. I had previously found that the womb measured three inches and a half, and was very badly retroflexed. I had considerable difficulty in getting a pessary to suit. But I finally succeeded, by a very long one, in restoring the womb to its natural situation. After making the incision through the abdominal wall, it required three quarters of an hour to find the right ovary. It was finally discovered buried in adhesions. The left ovary was easily found, and, to be on the safe side, both were removed; for, if this is not done, the operation will often give no relief. After removing the ovaries, I passed my fingers down into Douglas's pouch, and plainly felt the pessary pushing up the body of the womb, above the angle of flexure. There were several slender bands of adhesion which had kept the uterus in its abnormal position, but these had gradually been lengthened out. After the operation I removed the pessary; but, in thinking the matter over, I said to myself, "There will undoubtedly be some inflammation following the removal of the ovaries, which will fasten the womb in the position that it may occupy at that time. If I return the pessary and keep the womb in its normal position, the inflammation will tend to prevent its future displacement." So, before the patient came to, I replaced the pessary, and everything has thus far done well.

To return to the patient before you. I at first introduced a large pessary, but the womb was so tender that she could not stand the pressure. I then tried a smaller one, but this was so small that it did no good. I next used one between the two. She has been kept in bed, and she tells me now that she has no pain. The vagina has not yet been elongated sufficiently, but it will be, for the pessary projects from the vulva. Passing the sound, I find that the uterus is in a state of sinistral-lateral flexion—i.e., flexion to the left. By pressing upon the end of the pessary, I am able to raise the fundus of the womb, but this gives her pain. We shall have to wait a little before introducing a larger pessary. In the mean time the injections of hot water and the use of the suppositories will be continued.

A few more words about injection of hot water. It is not a panacea for all the ailments of the womb. Although it is an excellent remedy in the majority of cases, not only of tenderness, but also of hypertrophy of the womb, you will often be disappointed in it. It diminishes the size of an enlarged womb by its secondary effect upon the capillaries and tissues. If, however, you think that you can reduce a womb that measures three inches and a half to the normal two and a half by the use of hot-water injections, you will be disappointed. It can, perhaps, be reduced to three inches; but to reduce it more would require means which are heroic and unwarrantable under the circumstances, especially when we bear in mind that even these heroic measures may not be successful. You should always say to a patient whose womb is too large: "I can not make your womb as small as it was originally. You will have some trouble, some backache and some bearing-down pains, but I can make you much more comfortable until the change of life." You may also say: "If I can get you in a condition to become pregnant, there is a probability, although not a certainty, that the womb will grow smaller." Such a case will require, after confinement, remedies that will condense the womb—as ergot, strychnine, and quinine. Iron is not the thing. If given after confinement, it is very apt to do mischief. Iron has a tendency to cause a flow of blood to the womb. It will occasionally do great good, but more frequently it does harm. In those cases where a woman is weak and anaemic from uterine haemorrhage, a tonic is required, and the best preparations are the vegetable tonics. A good combination is a teaspoonful of Huxham's tincture—the tinctura cinchomor composita, with ten to fifteen drops of tinctura ignatiae.

The next patient is a lady, twenty-nine years of age. She has been married nine years. She had a miscarriage eight years ago. She lost a great deal of blood at the time, and the bleeding continued for four months. When I heard this, I said to myself: "If the haemorrhage continued so long, the miscarriage was probably induced;" but, on asking her if such was the case, she assured me that it was perfectly natural.

Why should there be bleeding after a criminal abortion and not after a natural one? This may be illustrated by fruit growing on a tree. When the fruit is mature, it drops off from a slight shake, and no injury is done either to the tree or to the fruit. But, if you pluck the fruit while it is immature, you will probably break the twig from which it grows. Again, and this illustration is a happier one, if the fruit is blighted from any cause, it will drop off readily without any injury to the tree. So, when a woman has a natural miscarriage, it is analogous to the falling off of the blighted fruit. The ovum is dislodged from its attachments, usually by the escape of blood behind it, and is thrown off as a whole—viz., the sac, with a little fetus inside; no membranes are left behind, and no injury happens to the womb. But when, by criminal means, a miscarriage is induced, it is like plucking the fruit while it still has sap-communication with the tree, and mischief results. The method most frequently employed to induce abortion is by puncturing the membranes. When this is done, the waters and embryo escape, but the adherent membranes remain behind. The secundines may remain after a natural abortion, but this is not the rule. In this woman the bleeding continued for four months, showing that the membranes remained attached to the womb, and acted like a polypus. This loss of blood was sufficient to produce a condition of anaemia. Menstruation then ceased. She has now partial amenorrhoea. She has been treated in the dispensary, and has been much benefited. Before coming to the hospital the menses were very irregular. This is the history that often follows serious haemorrhage at confinement. There is a strange peculiarity connected with loss of blood. It is frequently observed that where a person is losing blood in driblets she will bleed heavy. This fact is taken advantage of in aesthetic countries by butchers, who bleed the calves in order to have white and at the same time fat meat.

In the treatment of these cases we give iron in large
Concerning tissue, blood, to the uterus should be irritated by making applications to the fundus. The diet should be good, the digestive apparatus should be kept in order, and the bowels regulated. When the woman has grown fat from the loss of blood, it is not easy to restore the menses.

In a late number of the "Lanceet" Dr. Ringer gives a series of cases in which he used, with excellent results, the permanganate of potassium. He gives it in one-grain doses three times a day, gradually increasing the dose to two grains three or four times a day. He considers it to be the best remedy there is for bringing back the menses. He states that it does good, not by improving the blood, but apparently by a specific action on the uterine tissue. I shall try this remedy in my next case of amenorrhoea. This woman is doing so well that I do not think it necessary to administer it to her.

I have often seen women from thirty to thirty-five years old begin to grow fat, and soon the menses would cease. These women are frequently excessively anxious to have children. There is nothing more difficult than to establish menstruation in such patients. I have tried all forms of treatment. I have used the galvanic stem pessary, in some instances with success, and in other instances with failure.

I explain this condition in the following manner: At the change of life there is atrophy of the reproductive apparatus, and especially of the ovaries. At that time women, as a rule, either grow stout or else they grow thin. Now, although I have no post-mortem results to offer in support of my opinion, I believe that in women of the age I mentioned, and who cease to menstruate, there is atrophy of the ovarian structures. Such a supposition readily explains the reason why it is so difficult to establish the flow in these women.

The old code had not been restored, and that the old-code party were in the minority, this gentleman and two other well-known homœopaths severed their connection with the homœopathic society. A month later, four others in like manner resigned and abandoned their sectarian titles. It seemed probable that this break from the homœopathic ranks would have greatly increased, and, in the writer's judgment, fully one half of the members of the homœopathic society would have abandoned sectarianism had it not been that the old-code party made renewed efforts for supremacy, and impressed many with the belief that they would ultimately succeed in restoring the old code. The bold front and the assurance of success assumed by the advocates of the American code put an immediate stop to resignations from the homœopathic organizations and delayed their disintegration.

The months of February and March of the present year were devoted by the supporters of the old code to the perfection of an organization, the purpose of which was to restore, if possible, the old code in this State. Such an organization was formed, and its efforts during the year have borne fruit, as we shall see later. During the month of March, Dr. Austin Flint commenced a series of papers in this journal on "Medical Ethics and Etiquette," which were a commentary on the American code as viewed from the standpoint of its supporters. Of this commentary we shall examine but a single portion, that relating to the subject of consultations. As we all know, the rule of the American Medical Association reads as follows: "But no one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma," etc. Concerning this, Dr. Flint says: "The foregoing section has of late been made the subject of much discussion. Of the entire code, this section alone has occasioned dissenion."

Dr. Flint is here mistaken. The new-code party, or, to speak more strictly, those who drafted the new code, were dissenter from the old for more reasons than this. They found that prominent members of the profession, including many dignitaries of the American Medical Association, were the direct promoters of quackery and the use of secret nostrums, through the testimonials given in support of them, and when they found that the American code was apparently unable to repress these abuses, they endeavored in the New York State code to find an effective remedy. An examination of this code, especially its first section, will show how this difficulty was met, despite the fact that an effort of the same kind encountered defeat at a recent meeting of the American Medical Association. This certification of the value of nostrums by prominent members of the profession we personally consider as one of the most unfortunate developments of the last few years. It is true that some members of the profession in this city fell into the traps laid by cunning manufacturers, but the prompt action of the County Society checked the further extension of this evil. This was effected by the passage of a special resolution, as the Committee on Ethics found that the American code was defective on this point. When, in 1882, the attention of the American Medical Association was called to

**THE STATUS OF THE MEDICAL PROFESSION IN THE STATE OF NEW YORK.**

By HENRY G. PIFFARD, M.D.

Seventh and Concluding Article.

A few days before the meeting of the State society in February, 1883, a prominent homœopathic physician of this city said to the writer that, if the society stood by the new code, he, and probably other members, would resign from the homœopathic county society, and abandon their special designation; but that, if the State society re-enacted the American code, thus showing that the old spirit of intolerance still dominated the profession, he should not leave the homœopathic society, fearing, with others, that it would be still necessary for the protection of their interests to keep up a separate organization. As soon as it was known that...
the abuse in question, its Judicial Council refused to make any provision for its abatement, fearing, perhaps, to cast any reflection on those of its prominent members who were, or who had been, advancing their own interests at the expense of the mass of the profession. The first section of the State code we personally regard as the most important, and we would be perfectly willing to strike out all that follows if by so doing we could secure harmony on the questions now at issue.

Dr. Flint further says: "The writer of these remarks is one of many who think that the code is here open to objection, not, however, in spirit or intent, but in phraseology." From this it would seem that Dr. Flint approves the sentiment or spirit of the consultation clause, but does not approve of the language in which it is clothed. Let us, therefore, consider these points. The intent of this clause appears to be the prohibition of consultations with certain persons in consequence of their methods of practice, founded on a belief in the value of a special exclusive dogma, together with the rejection of certain aids approved by the regular profession. Dr. Flint, however, a little farther on, says that a practice based on an exclusive dogma is not valid ground for an objection to consultation. "Any physician has a right either to originate or adopt an exclusive dogma, however irrational or absurd it may be." We must here confess our inability to reconcile the last two sentences that we have quoted. That Dr. Flint should say that he approves of the "spirit or intent" of the restrictive clause in the code, and a moment later say that the adoption of an exclusive doctrine is not valid ground for refusing to meet a practitioner in consultation, certainly appears to us discrepant and inconsistent.

The code having forbidden consultation with certain persons, let us ascertain, if possible, what persons are intended. On this point Dr. Flint says: "At the time when the code was adopted by the American Medical Association, the irregular practitioners, so-called, were for the most part uneducated men, whose practice was not only based on an exclusive dogma, but professedly to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry. They were steam-doctors, or Thomsonians, botanical, or herb doctors, eclecistics, and the like. A system of practice based on the dogmas of Hahnemann had not then secured a hold on popular favor. A considerable number of those who became homoeopathic practitioners, as they are termed, were from the ranks of the medical profession, and had received a regular medical education. Since the adoption of the code, this system has obtained a legal recognition. It has its societies, colleges, and journals. The homoeopathic practitioners are an organized class, distinct from the regular profession. They are candidates for practice on the ground of a radical distinction in their therapeutical system, and it is on this ground that patients elect their services. Meanwhile, other systems in antagonism to the regular profession are comparatively insignificant as regards the number of practitioners and of patients."

Although the foregoing would seem to imply that the antithesis of the code was directed as much, if not more, against the various nondescript practitioners of the time as against the homoeopaths, the wording of the code itself would almost to a certainty indicate that it was specially intended to prevent consultations with the latter, as none of the other practitioners had even the pretense of an exclusive dogma. Dr. Flint, however, is, we think, in error when he states that these practitioners had not at that time acquired much hold on popular favor. As early as 1844 they had acquired sufficient hold to enable them to secure the repeal of the most important section of the Medical Acts of 1827, which, as we have already shown, opened wide the gates of the State to all forms of quackery.

Dr. Flint says: "Since the adoption of the code, this system (homoeopathy) "has obtained a legal recognition." This legal recognition we believe to have been the direct consequence of the code, and that it would never have been obtained except for the occurrences that grew out of the operations of the code. This is, of course, purely a matter of opinion, but in the present instance is based on a careful and extensive reading of the controversial literature of those days.

Continuing his commentary, Dr. Flint says: "It is fair to conclude that the framers of the code had no feeling of illiberality, and no intention to interfere with the practice of medicine, under any circumstances, in the cause of humanity. The code declares explicitly that in consultations the good of the patient is the sole object in view, and enjoins against declining consultations on the score of fastidiousness. The restrictions of the code are in no wise inconsistent with the demands of humanity in cases of emergency. In saying that certain practitioners are not to be considered as regular or fit associates in consultation, it is neither said nor implied that a physician should not see a patient, even with these practitioners, when humanity requires him to do so. The tenor and spirit of the code throughout are opposed to any act of professional inhumanity. Moreover, in particular cases the physician must be the judge of his duty in this regard."

The view of the code here taken is certainly a novel one, and one that, so far as we are aware, has never before been publicly advanced. Certainly the American Medical Association has never given its official sanction to this explanation of its consultation clause, nor has any other society, when called on to enforce the code, accepted such delinquents as a sufficient excuse for their misdoing. It must therefore be considered as a purely personal view, and as such does honor to its promulgator. Divested of unnecessary verbiage, it simply means that the American code permits consultations with homoeopaths in emergencies, and when demanded by the dictates of humanity, and makes the individual practitioner the judge of the necessities and proprieties of the case.

Let us compare this with the consultation clause of the State code, the first sentence of which reads as follows: "Members of the Medical Society of the State of New York, and of societies in affiliation therewith, may meet in consultation legally qualified practitioners." The second sentence is in antithesis to and an explanation of the first,
and reads as follows: "Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the dictates of humanity." It will be noted that this code neither obliges, recommends, or encourages consultations with homoeopaths; it simply permits them under circumstances which are specified, and leaves the choice of the individual physician interested to act as the judge of the necessities of the case. In what respect, we may ask, does this code differ from the American code as interpreted by Dr. Flint? We believe the veriest hair-splitter would find great difficulty in establishing even the minutest difference between the spirit and intent of the one code and the spirit and intent of the other. And yet this difference, whatever it may be, is the nominal cause of the hostile attitude of two important portions of the profession. What reason is there, then, for any further prolongation of the contest? None whatever, so far as the merits of the case are concerned, unless perchance Dr. Flint's interpretation of the code should prove not to be the correct one. There can be no question as to the truth of the assertion that until within a very recent period the American code has almost universally been interpreted as absolutely forbidding mixed consultations, under every and all circumstances, the individual practitioner not being permitted to use the slightest discretion in the matter, except at the risk of professional animal version. Humanity or emergencies found no place in the bosom of the heresy-hunter, whose special delight, apparently, was to detect some unfortunate practitioner whose heart had gained the better of his prudence. The issue here is plain. Either the old and orthodox interpretation of the code must be accepted, or else the one offered by Dr. Flint. In the latter event it certainly seems to us preferable to accept the phraseology of the State code, the meaning of which is clear and distinct, than to cling to the American, the language of which apparently permits of the most opposite interpretation. Dr. Flint, however, believes that consultations with homoeopaths should be forbidden for reasons which we find for the first time stated. He says: "The true ground for refusing fellowship in consultations, as in other respects, is a 'name and an organization distinct from and opposed to the medical profession.'" ... "It is to be hoped that the body from which the code emanated—namely, the American Medical Association—will adopt such modifications in the phraseology of this section as will place restrictions on consultations, not on the ground of doctrines or forms of belief, but on separation from and avowed antagonism to the medical profession." ... "If homoeopathic practitioners abandon the organization and the name, provided they have received a regular medical education, there need be no restrictions on consultations other than those belonging to other portions of the code, whatever therapeutic doctrines they may hold."

It would appear from the foregoing that Dr. Flint's main objection to the homoeopaths, from the consultation aspect, is the fact that they have formed medical associations outside those of the regular medical profession, and not in affiliation with them, and that, as a consequence of this, they should be denied professional recognition, and their patients should be denied the advantages of regular advice when such is needed. It does not appear even that emergencies or the calls of humanity would permit an evasion of the rule. In other words, the homoeopathic practitioners are to be denied recognition, and their patients punished simply because they have established separate organizations. We believe the existence of separate sectarian organizations to be a great evil—one of the greatest that at present afflict the body medical—but we are not disposed to hold up the homoeopaths to utter condemnation on account of their existence, when the medical profession itself is mainly the cause of their existence. We have already shown that the homoeopaths did not leave the regular societies voluntarily and for the purpose of organizing separate societies, but, in fact, were forced out of the established bodies. A recent writer, commenting on this very point, says:

"But there is, according to Dr. Flint, still a disqualifying cause which should exclude homoeopaths from consultations, and this is the assumption of a name and organization distinct from and opposed to the regular profession. There is undoubtedly force in this objection, but, if we look at the history of the rise and growth of homoeopathy in this country, the objection will be weakened, if not invalidated. Surely the doctor is old enough to remember the persistent efforts made in the beginning by the homoeopathists, when as yet they had no organization, to be admitted into our county medical societies, or in the case of members of the societies who adopted homoeopathy to resist expulsion. The numerous suits unsuccessfully brought before the courts to compel the societies to admit or retain them sufficiently attest that, if they now have a distinct organization, the fault is not on their side. We thrust them out of doors, and now it comes with a bad grace from us to give as a reason for refusing fellowship with them that they are not in our house."

We have no hesitation, therefore, in asserting that Dr. Flint's proposition savors neither of justice nor propriety, and that some better excuse must be devised for excluding homoeopaths from consultation when the demands and needs of the sick render such consultations desirable.

While Dr. Flint's commentary on the code was being published in the columns of this journal the supporters of the American code sought to effect an organization of the physicians of this State in opposition to the State society, and with the avowed purpose of resisting any modifications of the code that did not originate with the American Medical Association. A vigorous canvass of the State was made in behalf of this organization, and numerous signatures were obtained to a paper pledging its signers to stand by the American code. This action necessitated the formation of another association, one opposed to the re-enactment of the old code. This latter body forwarded to each member of the regular profession of the State a postal-card bearing on its back the following words: "I, the undersigned, am opposed to the present code of ethics of the American Medical Association, and approve of the use of all honorable means to prevent its re-enactment in the State of New

* Dr. Thomas H. Han, in "An Ethical Symposium," New York, 1883, pp. 60, 61.
York." The majority of those who signed this declaration and mailed the card back to New York simply attached their signatures and addresses. Many, however, added a few words of comment. All of the cards that were returned to the city came under the eye of the writer, and from them we have copied the following words of comment:

"and all other codes, as thirty years adherence to it has proved its uselessness."—S. F. McF.

"and so is the — County Medical Society as a body."—R. L.

"I am strongly in favor of the abolition of all codes, considering any code unnecessary for the guidance of a gentleman, and useless for the restraint of others."—T. C. W.

"I think that the old code was a good one when adopted, but there are reasons why it should now be rejected."—S. P. S.

"I have practiced my profession since 1845, and do not hesitate to say that I do not recall the time or instance when the old code governed the conduct of men of good sense or repute."—E. V. K.

"I would much rather prefer no code at all. But, being obliged to choose under existing circumstances, I say, emphatically, give me the new code."—M. G. P.

"I heartily indorse this card. Had the same position been taken twenty years ago it would have been better for the people and the profession."—J. R.

"The more liberty we have, the greater amount of good we can do."—L. B.

"I regard the new code as a most unfortunate and unwise substitute for the old code. Abolish the whole thing."—J. M. N. K.

"I have protested against it for eighteen years, and will do all in my power to aid in its overthrow."—C. H. A.

"I believe in each physician practicing medicine according to the dictates of his own conscience."—F. W. C.

"Hope we will succeed. New York can afford to be not represented at the American Medical Association. If we make a bold stand I think we will win—we have the right side, any way. I am for no code."—R. F.

"After obeying and carefully observing the rules of the old code for many long years, I have become strongly opposed to it, and am in full accord with the new code; and am willing to do what little I can to maintain it in the State of New York.

"I see its opposers are working hard, almost moving heaven and earth to bring about its repeal; but I do not think they can succeed. It (the American code) is not in accord with the spirit of the age; it is against the common-sense law of the land, and the best sentiment of all classes of society."—W. B. A.

"I think a code of ethics for the medical profession as unnecessary as a book of etiquette for a true gentleman."—H. F. B.

"An unwritten code is as binding to an honorable, honest man, and a written code, however stringent or liberal, will have no influence over the conduct of any others."—H. A. B.

"I prefer not to be tightened up by any code; shall in the future do as I have done in the past—uphold the dignity and honor of my profession, in my own way, to the best of my judgment."—J. R. B.

"and I am opposed to the pretentious and hypocritical old code of the New York State Medical Society."—L. C.

"The new code does not cause irregulars to rejoice, nor does it encourage a single wrong; the new code is legal; it is the voice of the age. It is progress."—S. J. P.

"Most heartily."—F. W. A.

"In the name of humanity, decency, and liberal progress, Amen!"—H. L.

"I did not approve of the change, but, since it has been done, would not turn back."—C. S. P.

"I would prefer no code, but, if we must have one, let it be liberal."—O. C. F.

"believing no code as effective as any code,"—J. H. F.

"because it can't be lived up to in actual practice. We must meet irregulars, and, if gentlemen, we must treat them as such."—P. K. S.

"I am in favor of free consultations."—J. T. L.

"Patients first, ethics next, and liberal opinions all the time."—C. M. McE.

"I am in favor of the present code of ethics of the American Medical Association, and approve of all honorable means to effect its re-enactment in the State of New York, hoping that we may soon have it amended in a way that will leave all at liberty to counsel with all whom they please, and not admit (as the present code does) that the Legislature is competent to say with whom it is proper and right to meet in consultation. A code of medical ethics should ignore all sects in medicine."—L. B.

The foregoing comments certainly indicate a wide diversity of feeling on the questions involved in the present discussion, and the different standpoints from which they are viewed.

The next important event in connection with the code controversy occurred at a meeting of the New York Academy of Medicine in April last. This body, by virtue of its charter, is entitled to representation in the State society. Its by-laws, however (unlike those of the county societies), are not subject to the revision of the State society. The Academy has generally been regarded as the peculiar stronghold of the conservatives, it being claimed that they possessed a large majority in that body. Some question having arisen as to the right of the Academy to representation in the American Medical Association after the exclusion of the New York State society, it seemed important to the old-code party to place the Academy distinctly on record as a supporter of the American code. At a meeting of the Academy, held on the 19th of April, Dr. Austin Flint, Jr., introduced a series of resolutions dissavowing sympathy with the action of the State society, and pledging the Academy to renewed allegiance to the code of the American Medical Association. The Committee on Admissions of the Academy was also directed to report for membership only such persons as would pledge themselves to support the old code. The resolutions were adopted by a large majority, obtained by the very simple expedient of assembling the old-code members by means of a secret circular, and without notice of the proposed action to the other side. The detailed proceedings of this meeting of the Academy have obtained a very wide publicity, and need not here be rehearsed. It was at this meeting that Dr. Flint, Jr., first appeared as the virtual leader of the old-code element, and indicated that the policy to be pursued would be characterized by the forter in re, rather than the muerit i modo. In other words, opposition was to be overcome by brute force, rather than by an appeal to argument and reason. This, indeed, was so thoroughly characteristic of the methods that for years have prevailed in the American Medical Association itself that we need not be surprised at anything that is done in its name. The effect of this action in the Academy.
was not all that was hoped by its supporters. Instead of strengthening the old-code party in this city, it distinctly weakened it. Many gentlemen whose bias was in favor of the old code, and who were willing to vote for its restoration, recoiled at the means that the leaders of their party seemed disposed to adopt, and declined to follow them farther. This was most conclusively shown a few months later.

The American Medical Association met early in June, and when the members assembled they found themselves confronted with an order from the Judicial Council, notifying them that they would not be permitted to register and take part in the proceedings of the meeting unless they signed a pledge of fidelity to the code of ethics. This pledge terminated with the words: "I will use my best efforts to maintain the same, and in testimony whereof, I hereunto affix my name." A careful examination of the constitution and by-laws of the association fails to discover any authority for this action of the Judicial Council. It was a pure assumption on their part, for which they possessed no warrant whatever. This action of the council does not surprise us; in fact, nothing that this body should do, or attempt to do, would surprise us. We were, however, immeasurably surprised that any of the members of the association were willing to be thus deprived of their liberty of action, or to deprive their fellow-members of theirs. We believe that the majority of the signers could hardly have been aware of the full intent of the pledge they were signing, as it virtually binds them to use their best efforts to maintain forever, without change, the present code of the American Medical Association.

We see in this act of the Judicial Council and of the association a striking example of the dangers that beset every unchartered and irresponsible body; a clique, once getting into power, hold the members at their mercy, and are enabled to trample on their rights at any moment, without fear of being held accountable, either as individuals or as an association. Not so in a chartered society, even with by-laws identical with those of the American Medical Association. Such a society would have been compelled to admit its regular members, irrespective of signing or not signing such a pledge. Doubtless the old-code members of the New York Academy of Medicine would be very glad to exclude from the meetings such of its members as do not approve its present code and by-laws; but they know such an attempt would prove futile. In a chartered society, every member knows, or can readily learn, his rights, and neither a ring, clique, nor even a majority in the society, can deprive him of them against his will. In an unincorporated society, however, anything may be done that at any time a majority approves, and there is no redress for those who may be injured thereby. For instance, in the American Medical Association a majority could, by mere vote, pass a resolution expelling all members who are opposed to them, and the expelled members would not be able to defend, or regain, their rights through an appeal to the courts. In fact, something very like this was done a few years ago. The writer attended a meeting of the association in 1863, and paid his fee of five dollars, which at that time entitled him to life-membership, without further payment of dues. A few years later he, in common with other members who had joined the association on similar terms, was informed that his life-membership would be forfeited unless he maintained it by a further annual payment of five dollars. This was a most unmistakable breach of contract, and violated the commonest principles of honesty and morality. The instance is cited simply as an example of the many arbitrary acts of the association, and to show how any act may be done by any voluntary, unincorporated society. Despite these facts, there are those who desire to see the incorporated societies of this State subjected to the control of such a body. We can hardly believe that the gentlemen holding these views have given any very careful consideration to the subject. In common with the majority of the profession, we approve of the existence of a national medical association, but it should be one devoted to scientific pursuits only, and should not attempt to interfere with medical politics in any manner. If the American Medical Association would reorganize on such a basis, New York State, we believe, would be unanimous in its support. If it continues as it is, its existence is but a question of a very few years.

The refusal of the American Medical Association to permit those who did not approve its code to participate in the proceedings of the Cleveland meeting, thereby preventing any discussion of the subject, has proved to be one of the most valuable allies to the cause of the New York State code. It was generally supposed that the advocates of the American code in this State would endeavor to secure desirable modifications at the Cleveland meeting, and many signatures were obtained to the old-code papers in consequence of this impression. The warrant for this belief was the fact that Dr. Flint in his commentaries had expressed his dissatisfaction with the code, as already shown in the present paper, together with the peculiar wording of the papers sent for signatures. In fact, many signatures were obtained on the express representation that a change of the code would be attempted by the members from New York. No such attempt was made, and some of the old-code signers, now fully appreciating the fact that no change may be expected by the association, and not approving the code as it stands, have withdrawn their support and influence, and have given them to the State code. We believe that a majority of the old-code supporters gave their signatures not from a fondness for the old code, but from a belief that all changes in it should originate with the association. Many have the idea that the association possesses some sort of jurisdiction over the profession of the State, and that resistance to its by-laws is a species of rebellion against constituted authorities. This idea is an absolutely false and mistaken one. The association has no more jurisdiction over the different State societies than the American Geographical or the American Dermatological Society has. Moreover, there is no process by which it could obtain such jurisdiction. No single State in the Union could give it a charter that would enable its power to be exerted beyond the limits of the State granting the charter; while the best that the United States could do would be to grant a charter the jurisdiction of which would be coextensive with the
District of Columbia. Congress has, for instance, the power to establish a medical college within the limits of the District, and to make the diplomas of the college licenses to practice within that area, but it does not possess the power to make them valid in any State in the Union. Such power exists solely in the respective States.

The profession of this State, and of other States as well, should remember that they are not doctors by divine right, or the grace of God, but simply through the will of the various State Legislatures. It is this which gives them a legal right to call themselves "doctors," and permits them to practice their profession. The Constitution of the United States guarantees a certain amount of freedom in the exercise of religious privileges, but it makes no such guarantees as regards the exercise of the legal, medical, or any other profession or trade. These rights the States reserved at the time of the formation of the Union, and since then have never yielded their prerogative to the national authorities. The action of the New York State society has been likened to the action of the Southern States at the commencement of the late "unpleasantness." It should be remembered that at the time of the formation of the Union the various States entered into a compact with each other, and that their succession was a breach of that compact. The Medical Society of the State of New York, however, never formed any compact, or entered into any contract with the American Medical Association or with any of the other States, nor, so far as we are aware, did any other State. There is therefore no analogy between the relations of the various States to the Union and the purely voluntary relation of the different State societies to the American Medical Association. The latter can, at any time it chooses, and for any cause, refuse to admit the delegates from any of the States. In like manner any of the State societies can sever its existing connection with the American Medical Association whenever it deems it to be to the interest of the profession of the State to do so.

In 1882 the New York society considered that it was better to relinquish its connection with the American Medical Association than to continue the connection, subject to the objectionable by-laws of the latter body. The association, on the other hand, thought it would be better to dispense with the representatives from New York than to alter its by-laws. This it had a perfect right to do, and no one, so far as we are aware, has found any fault with it for so doing. The only power possessed by the association is of a moral nature; legal power it has none. We should therefore judge its actions by the moral standard alone. The repudiation of its financial contract with its early permanent members, and the recent refusal to admit certain of its members, who under its by-laws were entitled to admission, should be sufficient to place the seal of condemnation upon the association, judged by the standard we have alluded to.

During the summer months there was an apparent cessation of active operations by both parties. Early in October, however, Dr. Fordyce Barker, the president of the New York Academy of Medicine, sent to each of the members a recommendation that the by-laws of the Academy be altered in certain respects. The Academy came into existence by virtue of a charter from the State granted in the year 1847. This charter conveyed certain rights and privileges, none of them, however, of a medico-political nature. The Academy, shortly after its organization, assumed such powers, and, through its moral influence, exercised them for many years. The alterations of the by-laws proposed by Dr. Barker involved a repudiation of its former political aspirations, and the resumption of a purely scientific status, as contemplated in its original charter. To accomplish this end it would be necessary for the Academy to repeal its allegiance to the American code. This would require a three-fourths vote of its members. When the matter came to a decision, it was found that a three-fourths vote was not in favor of the repeal of the code, but, to the surprise of many, there was a very decided majority in favor of such action. The Academy therefore stands today as adverse to the old code, but without power to repeal it, while the minority who are in favor of the old code have no power to enforce it against the wishes of a stronger adverse sentiment. This is certainly an anomalous state of affairs, which can not continue for any great length of time.

For some months it had been claimed by the supporters of the old code that the general sentiment of the profession in this city was in favor of the re-enactment of the American code. It was asserted that a majority of the County society were in favor of such action. The test was made at the annual election of officers in October. On this occasion both parties brought to the polls their full voting strength. On counting the votes, it was found that there were 220 in favor of restoring the old code, and 375 opposed to so doing. It seems quite certain that the old-code association had secured, early in the spring, a sufficient number of supporters to give them hopes of success. When the matter came to a vote, however, both in the Academy and in the County society, the result showed that there had been many breaks from the old-code ranks. Many gentlemen, who in the spring had hastily signed the old-code papers, on careful examination of the subject reconsidered their action. Many others regarded the occurrences that took place at the April meeting of the Academy of Medicine a sufficient ground for withdrawing their sympathies from the leaders of the majority on that occasion. A still greater number, however, we are satisfied, abandoned the fortunes of the old-code party in consequence of the failure of the leaders of that party to ever attempt to secure changes in the American code that so many of their followers considered desirable.

We may, I think, consider the code question as definitely settled, in this city at least, so far as regards the restoration of the code of ethics of the American Medical Association. The County society, the only body that can legitimately consider the question, at the last election, as on every previous occasion on which the matter has been brought forward, distinctly expressed its sentiments in opposition to the old code. It is true that the question can hardly be said to have reached a final solution in the Academy of Medicine. This body, with a limited membership, possesses but a limited influence on the mass of the profession, and it is of very little practical consequence.
which way it is decided in that body. The liberals, it is true, are in the majority, and will, without the slightest doubt, remain so, and may expect accessions both from the ranks of the present conservatives and from among those who in the future become members. As we have already shown, the code has been for many years practically in abeyance in the Academy, so far as its enforcement was concerned, and there is but little likelihood that its vitality will ever again be tested in that body. Such being the case, we are perfectly willing that those who profess to admire the code should continue to wear it as an ornament and a phylactery.

Before closing this series of papers, one or two questions of importance require notice. As we have already shown, certain of the county societies of this State repudiated the action of the State society in the matter of the code, and declared that they would stand by the old code and retain it among their by-laws.

It has been thought by some that such action on the part of the county societies would forfeit their title to representation in the State society. Such, however, is not the case. There is no provision in any of the statutes by which the State society is empowered to deny the county societies the right of representation, no matter how rebellious they may be as regards the edicts of the former body. The only way in which the State society can defend itself in the matter is by a direct application to the Legislature to have the charters of the offending societies revoked, as provided for in Sec. 2 of Article V of the by-laws of the State society. There is little doubt that, in the present state of public opinion, if such application were made to the Legislature, the request of the State society would be promptly granted. The county societies, however, should be aware that any code or by-laws they adopt contrary to the wishes of the State society are absolutely illegal and null and void. The importance of this matter suggested to the writer the advisability of obtaining the opinion of legal counsel concerning it, and to this end we submitted the following question:

What will be the effect if a county medical society adopts a by-law which is not in accordance with the ordinances of the Medical Society of the State of New York, or which does not receive the approval of said State society? The answer to this question was as follows:

"By the provisions of Sec. 14 of the Act of 1813 (Chap. 94), it is made 'lawful for the respective' (county) 'societies to make such by-laws . . . . as they shall think fit and proper, provided . . . . that the by-laws . . . . shall not be repugnant to the by-laws, rules, and regulations of the Medical Society of the State of New York,'

"And, by the provisions of Sec. 1 of Chap. 445 of the laws of 1866, it is declared to be 'lawful for any county medical society in this State . . . . to establish such rules and regulations for the government of its members as they may deem fit, provided the action of such societies receive the sanction of the said State medical society.'

"I am, therefore, of opinion that any such action on the part of a county society would be null and void and of no effect; in other words, as the law stands, the county societies can not adopt a by-law such as is suggested by the question, and any attempt to do so would be idle and of no avail."

We here leave the question of the codes and the status of the profession, with the statement that we have endeavored to be accurate as to facts, logical as to inferences, and moderate but candid in the expression of opinion. We can not but hope that the whole matter will receive a speedy solution, and one that will commend itself to the great majority of the profession in this State.

SOME CRITICAL REMARKS IN REGARD TO THE USE OF ANTIPYRETIC AGENTS IN TYPHOID FEVER.

By BEVERLEY ROBINSON, A.M., M. D., PROFESSOR OF CLINICAL MEDICINE AT THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

For several years past it has seemed to me that medical men are not to be found anywhere in regard to the proper uses and limitations of antipyretic medication, particularly in the treatment of some usual acute febrile disorders. In no disease is this statement more correct than it is with respect to typhoid fever. It is eminently fitting, therefore—as some of us are now engaged in combating a marked epidemic of this disease, and as, at relatively brief intervals, some new antipyretic agent is brought before the medical world with more or less readily acquired encomiums—to interrogate, from the experience which close clinical observation has afforded, the reasons why we give these remedies, and to ask ourselves if the results obtained are commensurate with the evils produced. The few cases just reported in this country of the use of kairine as a new antipyretic remedy in typhoid fever have, I confess, prompted me to enquire into my own experience in regard to a subject which otherwise I should have desired to avoid. As it is, I merely wish to direct attention to some timely considerations, which, I trust, will not be without value.

1. It is ordinarily assumed that high temperature in typhoid fever is necessarily a bad symptom, because it promotes tissue changes, which of themselves may occasion a fatal termination.

2. That we have in certain well-known agents—viz.: salicylates, aconite, veratrum, digitalis, and, latterly, kairine—efficient means to lower temperature.

3. While at times reference has been made to some of the objectionable symptoms occasioned evidently by the use of remedies to reduce high temperature, these sequels have not hitherto appeared sufficient to weigh equally with the presumed advantages from their employment.

In regard to the first-mentioned proposition, I would state that high temperature in typhoid fever is not necessarily a bad symptom. Of course, there are many cases in which typhoid fever is accompanied during life not only by intermittent or continuous high temperature, but this temperature is likewise a symptom of a series of grave symptoms. If the patient die under these circumstances, muscular and visceral changes of a degenerative kind are usually encountered. Per contra, I have seen many cases of typhoid fever in which the average temperature ranged for many days
over 102° or 103° Fahr., and yet no delirium, no excessive diarrhea or tympanites, no nervous disorder, was at any time present. I have also seen other instances in which there had not been a really high temperature during the whole course of the disease, and yet the termination was a fatal one, and the autopsy gave evidence of advanced degenerative tissue changes.

In regard to the second proposition, I agree that the agents mentioned will frequently lower temperature very considerably during several hours. I affirm, however, that their repeated use is essential if we wish to keep the temperature down in any given case; and, further, that, in many cases of a grave type, in which the temperature has had a high range almost from the inception of the disease, the ordinary antipyretic agents have had little or no effect upon the reduction of the pyrexia. In such instances, let it be clearly understood the case has been one of serious import, not merely by reason of the more or less continuous high temperature, but equally because most of the other symptoms denoted an unusually grave general condition. In regard to the third proposition, I would say in regard to cold baths, affusions, douches, and even the cold wet-pack, while I have at times, unquestionably, seen good results proceed directly from their use in the treatment of typhoid fever, nevertheless I have quite as frequently—nay, oftener—observed symptoms of lowered reaction—viz., cold and blue extremities, cyanosed and pinched features, unequal and feeble pulse, shallow and irregular respiration—which were obviously thus occasioned, and made me strongly question their utility. Quinine in antipyretic doses, whenever it lowers high temperature in an appreciable manner, does so, according to my observation of febrile disease, by reason of its lessening cardiac power and arterial tension. Now, then, if this be true, is it not dangerous to produce these effects in a disease where local congestions of viscera are so frequent? and, if the answer be affirmative, how, then, do we recognize its utility, with the exhibition under similar circumstances of frequently repeated doses of alcoholic stimulants, to sustain respiration and enfeebled cardiac power?

To attempt reduction of temperature in typhoid fever by means of the salicylates seems to me, unquestionably, bad treatment in the majority of cases: first, because the salicylates (with the exception of the natural salicylate, i.e., ol. gaultherinum) almost invariably produce stomachal disturbance and even rejection, and, further, their effect is, in anything like large doses, always depressing. Aconite does bring down temperature, as we all know, in a very remarkable manner, where disease is ephemeral in character; but can it be judiciously employed with this object in view in a prolonged, wearisome affection like typhoid fever, where every atom of vitality should be economized and not a molecule uselessly wasted? I am glad to add that rarely has any one made use, in latter years at least, of this paralyzing agent to lower high temperature in continuous fever. What is true of aconite is true, only in a greater degree, of veratrum.

Digitalis is, therefore, the single remedy which remains to be considered in this connection. If digitalis lowers temperature effectively, it does it by strengthening, equalizing, and slowing the cardiac beats, and by increasing arterial tension, especially in the smaller vessels. If, therefore, the heart be weak, irregular, unequal in its action, as it often is in grave cases of typhoid fever, it appears rational to make use of moderate doses of digitalis. But even in regard to the use of this drug a word of caution is required if we go beyond a somewhat restricted limit of dose. Digitalis is a cumulative remedy, when long continued, and, if given in large doses, or too frequently, instead of steadying the heart, it too often makes the cardiac beats more rapid, unequal, and wavering. It is also at times rejected by the stomach, and for this reason alone we are compelled to abandon its use. Further, if we give only such doses internally as lead additional power to cardiac muscular contractility, is the use of digitalis in grave cases of typhoid fever altogether without drawbacks? Let it be remembered that it is in these very instances that degeneration of cardiac muscular fiber is feared and likely to occur. If this be true, is it rational to make this organ contract with acquired energy when the object to be attained—viz., the reduction of temperature—is probably far less to be desired, on the one hand, than the acute dilatation of the cardiac cavities is to be dreaded on the other?

In regard to the third proposition, I claim already the right to be heard, and I would further direct attention to the following considerations: Of course, if high temperature were invariably a dangerous symptom, or if by its reduction, even though temporary, we might expect the general condition to be improved, we should surely be usually justified in using the means to produce the desired result. But, as a matter of fact, high temperature is not, as I have already stated, of necessity allied with other symptoms which directly imperil life. Temperature may be high (not excessive)—102°, 103°, 104°, or even 105°, Fahr.—and yet the pulse and respirations may be regular, and neither rapid nor weak. The nervous symptoms may likewise be of relatively mild type. Why, therefore, consider the mere lowering of the temperature so important? Almost every acute infectious febrile disease has a normal march toward recovery, or occasionally shows a sure progress toward death. If this premise be admitted, it follows that our efforts should not be in the direction of too great interference with the symptom, high temperature, when other symptoms are beginning. In many instances, moreover, it as definitely represents an integral, essential part of typhoid fever as does any one among the characteristic anatomical lesions.

Further, if in our methods of managing acute diseases we abstain from the use of disturbing agents with great power for harm, we at least manifest a degree of commendable caution for which our patients should be grateful; but when, as in the last antipyretic drug presented to our notice, we find that at a certain period of its exhibition the patient is attacked with a severe chill, and that, even while the drug is being given in quite large doses and at short intervals,
the temperature has risen almost to the height reached before it was begun, it is full time to stop and ask ourselves, Cui bono?

In the words of Jenner, I conclude by saying that that man will be most successful in treating typhoid fever "who, when presenting an active remedy, weighs with the greatest accuracy the good intended to be effected against the evil the prescription may inflict, and then, if the possible evil be death, and the probable good short of the saving of life, holds his hand."

TWO CASES OF
AMPUTATION OF THE PENIS,
WITH TRANSPLANTATION OF THE URETHRA INTO THE PERINEUM, ON ACCOUNT OF EPITHELIOMA.

BY JOHN A. WYETH, M. D.,
PROFESSOR OF SURGERY IN THE NEW YORK POLyclINIC; SURGEON TO MOUNT SINAI AND ST. ELIZABETH HOSPITALS.

CASE I.—F. F., aged fifty-six, a German by birth, married, and a cabinet-maker by trade, presented himself, March 9, 1883, for treatment at my clinic, at the New York Polyclinic, having been sent to me through the courtesy of Dr. C. W. Pfeiffer, of this city.

He gave the following history to the class: Ten weeks before, he noticed a pimple on the prepuce, which had always been adherent to the glans. He denied all venereal disease and the possibilities of contagion. From the initial pimple the disease had spread, slowly at first, but more rapidly within the two weeks prior to his applying for treatment.

The anterior third of the penis was greatly swollen (as represented in Fig. 1, made from an accurate drawing by my friend Dr. J. A. Andrews), and on one side, about one inch and a half from the meatus, there was a phagedenic perforation of the tissue, through which the entire flow of urine escaped. The inguinal and lumbar glands were slightly enlarged, and the skin of the patient was of a pale-yellowish hue.

The diagnosis of epithelioma was made, and was subsequently confirmed by my colleague, Dr. Gerster, and by my friend, Dr. E. A. Banks, whose wide experience in diseases of the genito-urinary organs has been of invaluable assistance to me. Amputation was advised for the following reasons: The stench from the phagedenæ was exceedingly offensive. It was doubtful whether the glands were enlarged as a result of inflammation or of metastasis. The comfort of the patient was greatly interfered with, and it was believed that his life would be prolonged by the operation.

The operation was performed before the surgical class of the Polyclinic, in the operating-room of Mount Sinai Hospital, on March 18, 1883. The procedure was that which is advised by Humphrey in Holmes's "Surgery." A ligature was applied around the organ close to the pubes, and the penis was cut smoothly off as near the ligature as was possible. The bleeding vessels of the corpora cavernosa having been tied, the serotum was transfixed at the perineum, and the urethral tube was dissected out from between the corpora cavernosa for an inch and a half, and then turned back through the serotum to the perineum, where the end was split up for half an inch on the upper wall, and the edges sewed to the incision in the perineum.

Fig. 1.

The serotum was carried up and sewed to the integument of the pubes, completely covering in the stump of the penis. A drainage-tube was passed through the serotum from the upper incision to the lower projecting part in front of the urethral opening in the perineum.

Fig. 2.
The temperature, which had been as high as 102° F. previous to the operation, was 102° 2' fourteen hours after, and declined gradually to 99°. The wounds healed promptly, the patient was discharged May 14th, and in June he returned to his work. I saw him a few weeks after this date, and found that the glands were of normal size, his skin had assumed a more healthy color, he had gained in weight and strength, and he believed himself cured. He urinated freely through the new opening, and was comfortable. Since that time I have not heard from him, as he changed his address and has not reported to me.

The microscopic examination of the tumor proved it to be epithelioma.

Case II.—G. D., aged thirty-eight, a native of this country, married, and by occupation a butcher. Came under observation at Mount Sinai Hospital September 12, 1883. He denied positively all venereal disease. Arcus senilis was well marked. His family history was negative. He had congenital phimosis, and for several years he had noticed a pimple on the mucous margin of the preputial orifice. Nine months before, a discharge of pus commenced from this sore, which, however, did not increase in size until five months later, when it became greatly swollen, painful, and discharged a considerable quantity of fetid pus.

On admission to the hospital, the tumor was two inches in diameter, and occupied the anterior half of the organ. It had the usual cauliflower appearance, and emitted a penetrating and offensive odor. The patient complained of pain except when resting on his back, and a stinging sensation during efforts at micturition, which were prolonged and ineffectual. The inguinal glands were not markedly enlarged. A disinfectant wash was used and amputation was advised, and was performed September 18th.

Exactly the same operation was done as in the preceding case. There was found to be a close stricture in the membranous portion of the urethra, which was dilated. The night following the operation the drainage-tube was carelessly allowed to get over the orifice of the transplanted urethra, permitting the urine to run up the tube and infiltrate the seromum, which accident ultimately caused considerable sloughing of the tissues between the two tunics vaginales. The temperature rose on the second day to 104° F., and, after this, gradually declined to the normal. The wounds and the sloughing surface healed rapidly, and the patient was discharged, in good condition, on October 28th.

November 11th he came before the class at the Polyclinic. The wounds were perfectly healed, he had gained in flesh and strength, and passed his urine easily and without discomfort. He reported that he had returned to his work as a butcher.

A Providential Accident.—A patient with locomotor ataxy consulted Dr. W. A. Hammond, of New York, who advised him to go to bed, and remain there for at least six months. The patient said it was impossible for him to go to bed, and if that were necessary he must give up treatment. On leaving the consulting-room, however, he luckily slipped and broke his thigh, and, being taken home, he completed his good fortune by calling in an "irregular practitioner," who kept him in bed for a year. At the end of that time the patient arose, cured not only of his fracture, but of his ataxy also, and has remained well ever since.—Med. Times and Gaz.

A NEW OPERATION FOR THE REDUCTION OF CHRONIC INVERSION OF THE UTERUS. *

By B. Bernard Browne, M.D.,
Professor of Diseases of Women in the Woman's Medical College of Baltimore; Fellow of the American Gynecological Society, etc.

After devoting a considerable amount of time to the study of the different methods of replacing a complete inversion of the uterus of long standing, and appreciating the difficulties and dangers attending the operations already devised, I concluded to adopt a new procedure in a case which resisted many of the methods referred to.

The simplicity of the operation, and the case and success with which it was performed, lead me to suggest it as one to be considered in all difficult cases.

The problem to be solved is, how to get the fundus back through the rigid and constricted cervix.

The injuries which frequently result from prolonged taxis, such as rupture of the vagina, rupture of the uterus, peritonitis, etc., are well known. Repeated failures at reduction have occurred to the most skillful operators. Up to this time Thomas's method, which consists in abdominal section over the cervical ring and dilatation from above, has been the only one that could be said to be absolutely sure of accomplishing the replacement in cases which had resisted the other plans—such as the rapid reduction by taxis; Noeggerath's method of indenting one horn of the uterus and re-inverting it first; Courty's method of passing two fingers into the rectum and dipping them into the cervical ring, with counter-pressure upon the fundus; Emmet's plan of receiving the fundus in the palm of the hand and spreading the fingers out in the vagina, with counter-pressure from above; or the very excellent and successful method of Dr. I. H. Tate, of Cincinnati, which consists in holding the cervical end of the uterus firmly between two fingers in the rectum and one in the bladder, while the thumbs press upon the fundal extremity.

The patient upon whom I operated presented the following history:

Mrs. I., aged twenty-eight, white, married ten years, has had two children, the youngest six years of age, and has had no miscarriage since. She is a large, stout woman, with thick abdominal walls, weighs about two hundred pounds, and has all the appearance of perfect health. Three months after her last confinement she had a severe hemmorrhage from the vagina upon rising in the morning. She laid at the point of death for nine weeks, and since then has been unable to be out of bed for more than two or three weeks at a time, suffering at intervals with hemmorhages, which have lasted from two to four weeks. She has had to be extremely careful in her movements at all times, for fear of bringing on a hemmorrhage. Her attending physician had made the diagnosis of "bleeding tumor of the uterus," and offered from time to time to remove it, which, fortunately, was not done.

In March, 1883, she came under my care, and was examined under an anaesthetic. The diagnosis of chronic inversion of the uterus was made. A prolonged effort at reduction by taxis did

* Read before the Baltimore Academy of Medicine, November 20, 1888.
not succeed in restoring the uterus, but a profuse hemorrhage was excited by the manipulations, and the vagina had to be tamponed with cotton saturated with dilute Monsel’s solution. A short time afterward another ineffectual effort at reduction was made. Then continued pressure with Garrod’s air-possay was resorted to, and used for six weeks, followed at the end of that time by another ineffectual effort at reduction by taxis. In October she came into the Woman’s and Child’s Hospital, where I made another attempt at reduction, trying Noeggerath’s and Courtly’s methods, but again with failure. The os could be plainly felt through the rectum, but the cervix was so firm and unyielding that it could not be made to dilate.

On November 24, the bowels and bladder having been evacuated, she was placed under ether, the inverted fundus was drawn outside the vaulta with a strong vulsella forceps, the openings of both Fallopian tubes were brought plainly into view, and an incision one inch and a half in length was made through the posterior portion of the uterus (avoiding the Fallopian tubes and larger vessels at the sides of the uterus). Through this incision Sims’s large dilator was passed up into the cervix and expanded to the fullest extent; the rigid tissues of the cervix were felt to relax; then, upon withdrawing this dilator, Nos. 2 and 3 of Hanke’s hard-rubber dilators (three fourths and one inch in diameter) were passed through the cervix. The finger was also passed to feel that there were no adhesions. The incision in the uterus was then sewed up with carbolized silk-worm gut, and, with slight manipulation, the fundus was easily replaced through the now passable constriction.

The whole operation was performed in less than thirty minutes. There was considerable hemorrhage from the uterine cavity when the uterus was first replaced. On the next day the temperature was 102° Fahl., but gradually returned to the normal condition, which it reached on the fourth day. During the first week she complained of severe pain in the uterus, but this was controlled by full doses of opium.

She was placed upon the table and examined on the 14th (twelve days after the operation). The cervix was somewhat patulous, but, with this exception, the parts were all in a normal condition.

Conclusions.

1. This operation is not proposed to supersede ordinary taxis in the reduction of chronic inversion of the uterus.
2. It is not more dangerous, but much more certain, than prolonged or rapid taxis.
3. We avoid the danger of bruising the tissues and rupturing the vagina.
4. As an operation for inversion, it is less dangerous than laparotomy.
5. Unless there be adhesions (which rarely exist), we can always feel certain of reducing the inversion at one operation.

---

**Book Notices.**

We have lately had occasion to notice a number of new works, and new editions of well-known text-books, on materia medica and therapeutics, and on a great proportion of them we have bestowed high commendation. To none, however, is greater praise to be awarded than to this fifth edition of Professor Bartholow’s. The appearance of the new pharmacopeia has rendered a number of changes in phraseology necessary, but, in addition to those, the volume bears evidence throughout of having been brought well up to the present state of our knowledge. With the author’s happy faculty for discerning just what aspects of the subject the practitioner of medicine needs to have most prominently set forth, he has chosen the plan of subordinating theoretical and purely scientific considerations to the practical; and yet, as he himself vigorously puts it, he has not allowed “utilitarian empiricism” to overshadow the scientific discussion of therapeutical principles.

In consonance with the general voice of the profession, we must say that practitioners of medicine can scarcely afford to forego the advantages to be derived from the possession of this book.

Dr. von Klein’s work seems to merit special commendation, not so much because it attempts anything extraordinary in the way of fine work in the cuts, but because accuracy of illustration is secured, and, above all, because the book is a notable endeavor to further the adoption of a uniform and precise Latin nomenclature—an anatomical language for use in all countries. With the exception of one or two slips, the Latin is unusually correct. We trust the author will be encouraged to extend his work into other branches than osteology.

The Pharmacopeia of the Northeastern Hospital for Children. Compiled by a Committee of the Staff. London: J. & A. Churchill, 1883. 12mo, pp. 32. [Interleaved.]

Such a book is commonly known among us as a formulary. The list of preparations in use at this hospital is rather more extensive than we are accustomed to see, but includes many which are tried and well known. A good feature of the book is a diet table, and two pages and a half of directions for bringing up babies.

NEW YORK, SATURDAY, NOV. 24, 1883.

THE ERIE COUNTY SOCIETY'S MEDICAL BILL.

The November number of the "Buffalo Medical and Surgical Journal" publishes a letter from Dr. E. M. Moore, of Rochester, addressed to the Committee on Legislation of the Medical Society of the County of Erie, in which, speaking of the committee's proposed bill for the regulation of medical practice in the State, the text of which was given in our issue of September 22d, Dr. Moore says: "While I have an instinctive dislike of any association with outsiders, it must be confessed that the plan your committee have in hand is the only one that can insure uniformity. Moreover, it is impossible to dictate anything on the subject of therapeutics. This, perhaps, is no great calamity, if men are thoroughly informed in the other departments of medical knowledge." The Erie County society's proposed bill has also received the formal approval of the Wayne and Westchester County societies.

It will be remembered that the original draft of the bill provided for a pro rata representation of the sects in a State examining board. Subsequently a modification was adopted making the constitution of the board in the proportion of six non-sectarians, two homeopathists, and one eclectic. We have before expressed our inability to see the occasion for more than one representative from each of the sects. We think the influential men among the homeopathists and the eclectics would not oppose a bill giving one representative to each of those sections of the profession. An outcry against such a bill must be expected from a certain class of doctors—a class always ready to pose as victims to persecution; but they will oppose any reasonable bill, license being their only idea of liberty. Since their blatant opposition must be encountered in any event, is it not better to strike for a satisfactory law at the start? We are satisfied that the pro rata principle, however modified, will temp to the very abuses it is so much desired to avoid. Dealing with sensible men, such as most of our legislators may be assumed to be, there ought to be little difficulty in showing the utter shallowness of the persecution plea.

Our purpose in quoting from Dr. Moore's letter, however, was not to renew our expressions of dissent from this particular feature of the bill, but rather to hold up the main concession of which he speaks as a concession that must be made. Not only will it not do to go before the Legislature with a proposition to exclude all representation of other "schools" than our own, but the thing would not be right even if it were feasible. We must not ask for legislation in the interest of the medical profession, but for measures in the interest of the community. We are very glad to see, therefore, that so potent a voice as Dr. Moore's is raised in favor of a mixed board.

INVERSION OF THE UTERUS.

It is to be presumed that few, if any, of our readers are unmindful of the degree to which original contributions to the advance of gynecology have been made in our own country. The American is decidedly in his element when a mechanical problem is to be solved, and the gynecology of the present time turns so largely on the mechanical adaptation of means to ends that our pre-eminence in that branch of the medical art is not to be wondered at, especially when we consider, too, that it was here that the interest and enthusiasm now felt in the specialty all over the civilized world practically took their rise.

Making all allowances for these considerations, however, it is not a little remarkable that there should be one particular form of injury of the uterus for the repair of which almost ever important step has been taken in this country—and that, too, an affection recognized in all its gravity from time immemorial, and not, as in the case of cerebral laceration, one that was really first brought to light here. Prominent among the procedures that have taken their rise in America for the restoration of the inverted uterus to its normal state, we may mention the late Professor White's plan of effecting reduction by the action of sustained elastic pressure on the body of the organ; Dr. Emmet's method of making a partial gain pave the way to final success, by sutures passed through the cervical lips and indenting the fundus; Dr. Noeggerath's happy thought of taking advantage of the natural action of the muscular tissue by indenting first one horn and then the other; Dr. Thomas's bold and direct solution of the problem, how to dilate the cervix, by approaching the orifice from above through an abdominal incision; Dr. Watts's device for accomplishing dilatation from above without laparotomy, by carrying the fingers into the hollow of the inverted organ by way of the rectum; and, finally, the latest expedient, described in this issue of the journal, by means of which Dr. Browne has succeeded, in an obstinate case, in dilating the cervix through an incision penetrating the uterine wall.

All these procedures are rational, and each has proved successful in actual practice. They are all in the highest degree creditable to the gentlemen with whom they originated, and they are no less creditable to American medicine. It is scarcely to be supposed that the list of possible devices likely to prove available is yet exhausted, but certainly great strides have been made in that direction, and whoever brings a new expedient into play not only makes the positive achievement, if he succeeds, of swelling the record of triumphs, but often holds out to others a suggestion that is pretty sure to be followed up and made the most of.

THE BIRTH RETURNS OF NEW YORK.

We have before alluded to the exceptionally low death-rate recorded in New York during the greater portion of the current year. It appears, even, that for several weeks past the deaths have been exceeded by the reported births—a feature somewhat novel in our vital statistics. It has been said that this was owing to an unwonted fidelity on the part of physicians in the matter of reporting births, and that it has been
brought about by the Health Department's having caused it to be understood among the profession that the penalties it was entitled by law to attach to the non-fulfillment of the requirements in such cases would now be exacted more rigorously than in the past.

Such an impression may be entertained by our city practitioners, and we hope it is. Our absolute death-rate, as reported, is undoubtedly higher in general than the facts really warrant. This anomalous state of things depends upon circumstances that space does not allow us to enumerate at present. But there is no doubt that the excess of deaths over births usually reported is due to the fact that the former are all reported, while of many of the latter no return is ever made. The Health Department is enabled to apply one practical test of the faithfulness with which births are returned, in that, when a child's death is reported, it can ascertain from its own records whether that child's birth was or was not reported; but, manifestly, this is an imperfect test, and the department would be quite warranted, as it is abundantly authorized, in enforcing the penalties prescribed for negligence in this matter. On this ground it is to be hoped that, whether as the result of some premonition to that effect, or in consequence of an awakening of our conscience to the duty of reporting births, the returns will in the future be more complete. As a matter of fact, however, the recent excess of births does not seem to be due so much to any such circumstance as to the remarkably low death-rate.

OUR QUARANTINE SYSTEM.

In the volume just issued by the Treasury Department, being the Annual Report of the Supervising Surgeon-General of the Marine-Hospital Service, for the fiscal year 1883, Surgeon-General Hamilton, we are glad to see, expresses himself pointedly in favor of the value of the quarantine system. He very properly denies that there need be any antagonism between the enforcement of quarantine and other measures of marine sanitation. The fact that no great amount of harm has followed the abandonment of the practice of quarantine by the English he imputes to the remoteness of England from the great sources of infection. Doubtless it is chiefly with regard to yellow fever that this explanation is intended to apply; indeed, it is largely with respect to that disease that Dr. Hamilton's remarks on quarantine are to be taken. It is pointed out that the nations of Europe are far from approving of the English policy, as was shown by the action of Spain in establishing a temporary quarantine against all English arrivals during the past summer.

Arguing, as he does, that a national quarantine system is a necessity with the United States, and supporting his position by quite an array of illustrative incidents in our past experience, Dr. Hamilton nevertheless insists that it ought not to be of the makeshift character hitherto employed. He objects to the station at Ship Island, for example, as situated too far from the course of vessels bound for New Orleans, and suggests the Grand Goletz or one of the Chandeleur Islands as a more suitable place. Besides the greater convenience and efficiency of a quarantine station at the latter situation, it would be less dangerous as a source of infection to vessels engaged in local trade.

The establishment of a permanent station at or near Cape Charles is urged, and the opinion of the sanitary conference held at Fortress Monroe is cited as agreeing in this recommendation. It is shown that, with a comparatively small expenditure, a well-appointed station may be established there.

MINOR PARAGRAPHS.

THE BRITISH GOVERNMENT AND THE CHOLERA IN EGYPT.

Professor Lankester, writing in the "Pall Mall Gazette," laments the failure of his Government to take an active part in the scientific investigation of the outbreak of cholera in Egypt, all the more from the fact that Great Britain is held morally answerable for the conduct of affairs in Egypt, sanitary as well as political. He intimates, too, that England could not have furnished any investigators qualified for such a work, and would probably have assigned it to a few medical students. Herein, it seems to us, Professor Lankester does his countrymen scant justice.

A SIMPLIFIED POLYSCOPE.

Dr. Baratoux, who has contributed largely to the adaptation of electrical appliances to medicine, has devised a modification of M. Trouvé's polyoscope which, in the form recently shown to the Paris Society of Biology, seems to have certain advantages over the photophore. A minute electric light is arranged in the hollow of a concave mirror, and the whole apparatus, including the handle, is but little more cumbersome than the ordinary laryngeal mirror.

THE "PLANET."

The November number, the eleventh of the first volume, dated November 15th, comes to us much improved in appearance. The size of the page and the general typographical appearance are those of the "Medical Record." We congratulate Dr. Nelson on the success which this change seems to imply.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending November 20, 1883:

Epidemic Diseases.—Small-pox is reported from Stone Fort, Ill., and the neighboring country. Scarlet Fever is prevailing in Trenton, N. J., where it has been found advisable to dismiss the pupils of a large school, to prevent the spread of the disease among them. Diphtheria is epidemic in New Brunswick, N. J., and Waterbury, Vt.

Trichiniasis has broken out in Thorn, in West Prussia.

The Infectious Diseases of Domestic Animals.—At a convention held in Chicago on the 15th inst., at the call of the
LETTERS TO THE EDITOR.

Commissioner of Agriculture, papers were read by Professor Law, of Cornell University, Dr. Salmon, of the Department of Agriculture, Dr. Parsons, of Wyoming, Dr. Gaisden, of Pennsylvania, and others. The convention was largely attended. Congressional legislation in regard to contagious pleuro-pneumonia was favored, also a Government inspection of meat for export. An extension of quarantine, so as to cover sheep, swine, and goats, was favored.

Rinderpest is reported by our consul at Breslau to have broken out in that city.

THE LATE DR. J. MARION SIMS.—At a special meeting of the Board of Governors of the Woman's Hospital in the State of New York, held at the house of the president, on the evening of November 15th, the following minute was adopted:

The sudden death of Dr. J. Marion Sims, on the 13th inst., is recognized as a grievous loss by all who are interested in the cause of humanity, and especially by those associated with him in this charity. From the day of its organization until his departure for Europe in 1861 he was its own surgeon, and practically developed the improved methods of operating which he had originated, notably the use of the silver suture, now found to be indispensable. During thirty years of his active life he devoted his talents, time, and influence to place this institution upon a successful basis, and earned the gratitude of the many suffering women who have been relieved. After his return from that visit to Europe he was elected a member of this board, and served with his wonted interest. When the Board of Surgeons was reorganized, to consist of four members, he accepted one of the newly created positions and resumed active professional practice in the institution.

After resigning that position he became one of the Committee of Surgeons, at the unanimous request of his colleagues and of this board. At intervals, when in Europe, he treated many important cases, and was equally appreciated in both continents. But his memory will be especially identified with this institution, where his reputation as one of the most eminent surgeons of the century was first developed.

Resolved, That the members of this board will attend the funeral of the deceased.

On the occasion of the twenty-ninth anniversary of the hospital, on Thursday, the 22d inst., one of the Lady Supervisors presented the institution with a bronze bust of Dr. Sims.

An Arrest under the Medical Practice Act.—"Dr." Thomas F. Blanchard, representing himself as a lung specialist, doing business at 911 Arch Street, Philadelphia, and also Medical Director of the "Germantown Sanitarium and Home for Consumptives" at Germantown, Pa., recently went to Glens Falls, N. Y., and opened an office at one of the hotels. He registered in the County Clerk's Office as practicing under a diploma granted by the Geneva Medical College, New York, dated June 3, 1849, and also a diploma granted by the Royal College of Surgeons, London, dated March 29, 1853. As both these dates occurred on Sunday, the "doctor" was arrested under the Medical Practice Act. He asked for a postponement to give him time to produce his diplomas, and, while the preliminaries for bail were being arranged, he escaped from the officer and disappeared.

The Hospital Saturday and Sunday Association.—It is announced that two hundred and ninety-three churches have agreed to take part in the collection this year. The Skin and Cancer Hospital has been admitted to the association.

The New York Infant Asylum.—The Grand Jury has failed to find an indictment against Dr. Caroline G. Marr, the resident physician of the country branch, who was recently censured by a coroner's jury.

OBITUARY NOTES.

JOHN LAURENCE LE CONTE, M. D., of Philadelphia, died on Thursday, the 15th inst., at the age of fifty-eight. He was born in New York, May 13, 1825, graduated from Mount St. Mary's College in 1842, and received his medical degree from the College of Physicians and Surgeons in 1846. In 1852 he removed to Philadelphia, where he has since resided. In 1857 he was attached to a party sent out to make a survey for an interoceanic railway across Honduras, and in 1867 he accompanied a surveying party on the Kansas Pacific extension. He entered the volunteer army as surgeon in 1861, and was subsequently appointed medical inspector with the rank of lieutenant-colonel, and served in this capacity until the close of the war. He was a member of and held office in many of the leading scientific societies in this country, and was also a member of a number of scientific bodies abroad. He was for many years a voluminous contributor to periodicals and to the transactions of these societies, his writings being principally on entomology, in which subject he was particularly well versed. At the time of his death he was chief clerk in the United States Mint at Philadelphia, a position which he had held for several years.

SIMON P. DRESSER, M. D., of Hinsdale, Mass., died suddenly on the morning of Thursday, the 15th inst., at the age of forty-three. Responding to an urgent call at four o'clock in the morning, he drove against an obstruction, was thrown from his carriage, and broke his neck. He was a member of the Massachusetts Medical Society and of the Berkshire District Medical Society.

Letters to the Editor.

THE NEW YORK INFANT ASYLUM.

New York, November 12, 1883.

To the Editor of the New York Medical Journal:

Sir: I furnish you for publication extracts from the minutes of the Executive Committee of the New York Infant Asylum, which will correct errors that have occurred in the statement published by Dr. Joel Foster and others in your journal.

Very respectfully yours,

Richard B. Kimball,
Secretary, Board of Managers

A meeting of the Executive Committee of the New York Infant Asylum was held, pursuant to call, on the evening of September 29, 1883, at the residence of L. M. Bates, Esq., at eight o'clock. Present: L. M. Bates, Dr. Joel Foster, Dr. William N. Blakeman, Archibald Turner, and Benjamin A. Willis.

L. M. Bates presided.

Benjamin A. Willis, being elected secretary pro tempore, acted as such.

The meeting having been called to order, the president stated that an epidemic was prevailing in the Mount Vernon Home—to consider which was the object of the meeting.

Dr. Joel Foster then made a statement to the effect that since the 1st of August last an epidemic of a fatal character had raged, resulting in fifty-one deaths, appearing in measles of a malignant form, different from any known to him in his experience—of an obscure character, recurring twice, thrice, four, and five times in the same patient, the sequence of which were most dangerous, being bronchial pneumonia, dysentery, and in other forms; the measles were attended with symptoms similar to scarlatina.

A meeting of the Executive Committee of the New York Infant Asylum was held, pursuant to call, on the sixth day of October, 1883, at the office of L. M. Bates, No. 345 Broadway, at 3 o'clock, p. m.

Dr. Foster submitted the report of the sub-committee, appointed September 29, 1883, Messrs. Foster, Burrall, and Goodridge, which was read by the secretary and ordered placed on file.

Colonel B. A. Willis moved, which was seconded, that this report of the sub-committee, the letter of September 29, 1883, signed by Messrs. Foster, Blakeman, Burrall, Goodridge, and Nicoll, with the subject matter thereof, be referred to the Executive Committee of the Medical Board, who report thereon to this board with all convenient speed. After discussion, this was adopted; ayes, Bell, Bates, Kimball, Turner, and Willis.

At a meeting of the Executive Committee of the New York Infant Asylum, held, pursuant to the call of the chairman, at 3.30 o'clock, r. m., at No. 55 Liberty Street, on Tuesday, October 30, 1883.

Present: The chairman, L. M. Bates, and Messrs. Clark Bell, Dr. William N. Blakeman, Dr. Joel Foster, Archibald Turner, and B. A. Willis.

The president, Mr. Bell, then laid before the committee a communication from the visiting staff to the board, certifying to the competency of Dr. Marr, of which the following is a copy, dated October 16, 1883:

To the Board of Managers of the New York Infant Asylum:

We, the undersigned, visiting physicians of the Mount Vernon branch of your institution, hereby desire to testify our faith in the competency of the resident physician, Dr. Caroline G. Marr, her zeal and energy under trying conditions, and at the same time wish to give it as our opinion that the mortality of the epidemic of measles, whooping cough, and diptheria, and their complications which have prevailed, under the circumstances, is not excessive.

A. N. Bell, M. D.,
George B. Fowler, M. D.,
E. Bradley, M. D.,
F. N. Warner, M. D.

October 16, 1883.

On motion, the communication was received and ordered placed on file.

The Executive Committee of the Medical Board, to whom were referred the communication of Dr. Foster and others, and the report of the sub-committee made to the committee October 6, 1883, made the following report:

New York, October 30, 1883.

To the Executive Committee, Board of Managers, New York Infant Asylum:

Gentlemen: The undersigned, members of the Executive Committee of the Medical Board of the New York Infant Asylum, have considered the communication of September 29, 1883, and the report of the sub-committee of October 6, 1883, referred to our committee, and respectfully report: "That we recognize no necessity for other medical service than that of the Medical Board so distinctly provided for in your own by-laws."

Respectfully yours,

A. N. Bell,
J. C. Thomas,
George B. Fowler.

The report was received, read, and ordered placed on file.

Attached is a letter of September 29, 1883, as follows:

Gentlemen: We all alike deplore the calamity which has befallen our Country Home at Mount Vernon. The epidemic which began during the month of August has already destroyed fifty lives, and during the past ten days fourteen deaths have occurred; which shows that the violence of the disease has not abated.

Evidently the means hitherto used are inadequate to control the disease. In this emergency we offer our united services to the asylum, requesting that full control of the medical and sanitary interests of the Country Home be delegated to us until the epidemic is ended.

(Signed) Joel Foster, M. D.,
W. N. Blakeman, M. D.,
E. A. Goodridge, M. D.,
F. A. Burrall, M. D.,
Henry D. Nicoll, M. D.

New York, September 29, 1883.

The Columbia Veterinary College Lectures.

2 East Thirty-third Street, N. Y., November 17, 1883.

To the Editor of the New York Medical Journal:

Sir: In the journal of to-day attention is called to a course of lectures now in progress at the Columbia Veterinary College, in which is announced a lecture by myself on "The History of Surgery." I would like to have it known that this announcement has been made without authority from me, and even after my positive refusal to deliver any lecture, and I respectfully ask the use of your columns for that purpose.

Your obedient servant,

William T. Bell, M. D.

Proceedings of Societies.

New York Pathological Society.

A stated meeting was held November 14, 1888, Dr. G. F. Shrdy, President, in the chair.

A Tooth removed from the Antrum of Highmore.—Dr. J. A. Wyeth presented the specimen, which was removed from a woman, twenty-six years of age, who came to him a year ago with trouble with the antrum of Highmore on the left side. Thirteen years previously she had measles or scarlet fever, and since then, from time to time, had felt painful sensations in the antrum. A dentist extracted a tooth on the corresponding side, and, through the hole left by one of the fangs, pus escaped more or less for seven or eight years afterward. Dr. Wyeth extracted two more teeth, and trephined the antrum for the purpose of through-drainage. On opening the antrum, he found a tooth, which was evidently one of the permanent teeth that had taken a wrong direction, entered the antrum, and acted as a foreign body. It was the only case of the kind which he had seen or heard of. The symptoms had not entirely disappeared, which would seem to indicate the presence of necrosed bone that would have to be removed at a future time.

Dr. G. L. Peabody thought such cases must be very rare.

Embolism of the Basilar Artery.—Dr. Peabody presented a portion of the base of the brain and the heart of a man who entered the hospital last spring. His mother had died of heart disease. Two years ago he had suffered from rheumatism. Ten weeks before entering the hospital he began to suffer from symptoms which might be attributed to disease of the heart and kidneys, which were present: dyspnoea, palpitation, headache, and anaëresia in greater or less degree, as the case progressed. Some hours before death he became very silly, without any apparent reason for it; the heart's action became more irregular, and incontinence of the faces and urine took place. The anaëresia became excessive. He then grew violent, and it was necessary to put him into a strait-jacket. Nourishment had to be administered by the stomach-tube. The amount of urine decreased to fourteen ounces in the twenty-four hours. In the evening he became quiet, and passed into a state of stupor and died. At the autopsy the basilar artery was found completely occluded by an embolus, which had cut off all circulation to the portion of the brain supplied through that channel; in other respects the brain was normal. The heart was large, both ventricles markedly dilated, with signs of general endocarditis, the chief lesions resting in the mitral valve, the cusps of which were markedly thickened and stiffened, the surfaces being rough. There were signs of acute pleurisy just over the site of a pulmonary hemorrhagic infarction. The kidneys were the seat of extensive lesions. The liver was enlarged. The parietal and the visceral layers of the pericardium were adherent. The chief...
interest in the case related to embolism of the basilar artery, which Dr. Peabody regarded as a rare condition. It seemed strange that the embolus had not become lodged before reaching this position. The accident probably occurred at about the time the man became delicious. It was not difficult to understand that the nutrition of the brain had not suffered much, considering the extensive anastomosis in this region.

Dr. Wyeth asked Dr. Peabody what he considered the immediate cause of death.

Dr. Peabody replied that the question was a difficult one to answer, inasmuch as there were so many conditions present, any one of which might have caused the fatal issue; the heart lesion, however, was in some way the probable cause.

Dr. Wyeth said that he had been personally cognizant of two cases in which thrombosis of the basilar artery had been considered the cause of death, the explanation being, it was supposed, that anemia of the medulla andpons had resulted. Other cases had also been reported. Eight years ago he proposed to tie both vertebral arteries in a case of epilepsy, millitary aneurysm then being considered a probable cause of the disease; but about that time one of the two patients referred to died, as was supposed, of anemia of the parts supplied by the basilar artery, which was the seat of thrombus. As it seemed that the condition which he was about intentionally to produce had in this case accidentally occurred and resulted in death of the patient, he decided not to perform the operation. A Liverpool surgeon, however, had tied the vertebral artery in a number of cases of epilepsy, in some of which a cure seemed to have been effected. In others there had been improvement, and in none had any evil result occurred attributable to the operation.

Ivory Exostoses of the Ethmoid.—Dr. Herrmann Knapp presented a specimen which had been removed from a woman forty-five years of age, who died about four days after the operation. The patient had suffered from nasal polypi for about fifteen years. Twelve years ago they had been removed for the first time. In the course of years four more such operations had been performed, the last one two years ago. They then grew much faster, and six weeks ago, when she went to Dr. Knapp, both nostrils were occupied by polypi, one of them being almost completely occluded. At the inner side of the orbit there was a hard tumor, about as large as a filbert, crowding the eye toward the temple and somewhat forward. He advised removal of the polypi as far as possible through the anterior nares, and Dr. Lincoln performed the operation, extending it over four or five weeks. A considerable mass of the growths was removed, and Dr. Lincoln said he could not go farther. Dr. Knapp concluded to remove the bony tumor, after which better access could be had to the polypi. No difficulty was experienced in the removal of the tumor; it was extracted with so little injury to the tissues that not the slightest apprehension of unfavorable reaction was entertained. The nasal cavity was then explored as far as possible through the nostrils with a sharp spoon. The frontal sinuses on that side was found full of polypi, which were removed. They were the ordinary so-called mucoidal polypi. The patient did well during the first twenty-four hours, and then began to complain of headache, and became somnolent. The temperature rose to about 104° F., and she died on the fourth day, comatose. At the autopsy the dura on the right side, especially along the larger vessels, was completely infiltrated with pus; the meshes of the pia and the space beneath were filled with serum; the cerebral convolutions were considerably flattened. On the left side, on which the operation had been performed, the purulent infiltration was much less marked, and still less at the base of the brain. No direct transmission of the inflammatory process from without inward was traced. There was no irritation at the seat of removal of the tumor. The ethmoidal cells on both sides were almost completely plugged with polypi. There were also polypi in the frontal sinuses at points which it was impossible to reach during life. The sphenoideal cells were plugged with polypi, and at one point contained cheesy pus, which doubtless had existed at the time of the operation, and was one of the prime factors in exciting the fatal meningitis. The tumor had developed from the ethmoid bone, and was of ivory-like hardness. The method of removal was certainly the correct one, and, doubtless, the fatal result was not due to the operation, the way having been previously prepared by the polypoid growths and the purulent accumulation of which they had been the cause; but the operation might have had some influence in fanning the flame that already existed. As to the necessity of treating polypoid growths there could be no doubt. Dr. Knapp had seen cases in which, by neglect, they had extended to the ethmoidal cells and the frontal sinuses, crowding upon the bones of the orbit, and leading to a condition which no human hand could remedy. In one instance they had been operated upon sixteen times, and at last became sarcomatous in character. Their presence in the cells of the bones caused retention of the secretions, and was liable to lead to the condition more frequently seen in the mastoid cells, which, sooner or later, led to abscess, thrombosis, meningitis, etc. They should be dealt with early. The same was true of exostoses of the orbit; while small they could be removed with success.

Hydatid Mole.—Dr. Charles Hertzmann presented a specimen which had been passed at the fifth month of pregnancy, small masses having been first passed at the commencement of the fourth month. He presented it for the purpose of referring to its minute structure, and agreed with the opinion as to its true nature entertained by Virchow.

Carcinoma of the Breast.—Dr. A. G. Gerster presented a breast and some of the axillary glands removed from a woman, sixty-one years of age, who had given birth to nine children. She came to the German Dispensary in May last, on account of a slight discharge of blood from one nipple. The most careful examination failed to reveal any induration of the shrunk gland, or of the axillary glands. Nevertheless, Dr. Gerster had suspicions of cancer, and, as the woman did not wish to have the breast amputated at that time, she was advised to return from time to time, that the progress of the condition might be watched. The physicians at the dispensary said, on his return in the autumn, that there had been no change in the condition. Dr. Gerster, however, examined the axilla carefully, and found induration of the glands, and then no longer entertained doubts as to the nature of the disease. The breast, together with the affected axillary glands, was amputated for carcinoma. This was the third case which he had seen in which induration of the lymphatics in the axillary space pointed plainly to malignant disease while the only condition observable in the breast was a slight sore at the nipple. He called attention to the difficulty of discovering enlargement of the glands in the axilla when it was not considerable.

Amputation at the Thigh for Knee-Joint and Phlegmonous Inflammation.—Dr. Gerster also presented the leg of a child, which had been amputated on account of the presence of a complicated pathological condition. The patient had had strumous disease of the knee joint for a considerable time; it was suddenly taken with fever, and was seen by a physician, who took the trouble to be rheumatism, and poulticed the joint. Phlegmonous inflammation was thereby superimposed upon the strumous affection, and extended well up on the upper third of the thigh. The parents, who regarded the child’s condition as comparatively good, were surprised to hear amputation proposed. The suppuration was very extensive, and it was nece-
sary, in order to get a sufficient amount of flap, to employ some of the affected integument. A strong solution of the bichloride of mercury, 1 to 500, was used. The wound healed by first intention, and the patient made a good recovery.

Referring to the first case, Dr. W. GILL WYLLIE said that in one instance he was led to suspect impingement of the axillary glands from tenderness; an increase in size could not be determined by the feel. His suspicion was correct, as the operation proved.

Dr. HEITZMANN asked Dr. Gerster if he meant to state that the use of the strong bichloride solution had been the means of bringing about the good result in the second case.

Dr. GERSTER replied in the affirmative. In no other way than by insuring the destruction of germs could primary union have been obtained in the phelegmonous tissues. Simple cleanliness would not have produced the result.

CANCER OF THE ESOPHAGUS.—Dr. E. K. Henschel presented a specimen, obtained from a man seventy-three years of age. The patient first came under his observation in April, 1881, when he complained of eructations of gas and disturbance of the stomach, the symptoms not being marked. The next time he saw the patient was in March, 1882, when he had some difficulty in swallowing solids, but examination disclosed nothing positive. He consulted physicians in Paris and Brazil, while in those places, still complaining of eructations. In September, 1882, there was some dullness at the right of the sternum. At the beginning of the present year he began to lose flesh, the dullness to the right of the sternum increased, and respiration near that point was absent; he could at last take only fluids, and these were more or less regurgitated. Dr. Janeway saw the patient with him, at which time he had lost seventy pounds in weight. After passing a bougie, two large clots of blood were spat up, and the man then improved somewhat, gaining twenty-five pounds. In October, pleurisy over the lower right lobe developed, but improved until, on November 4th, bronchi-tis with expectoration appeared, and on the 5th a gurgling, as if of breaking down of lung tissue, was heard about the middle lobe on the same side. On the following day there were indications all over the chest of fluid exudation. The man became unconscious, and expired some thirty-six hours later. The post mortem revealed stricture of the esophagus by carcinoma. An opening had taken place at the center of the ulcer into the right lung. The pleural cavity was filled with a fluid which gave forth an odor as if it had come from the stomach.

Dr. PEABODY remarked that this specimen, which he had examined, was interesting because of the perforation which had taken place into the lung, through which the contents of the stomach had entered by regurgitation and had partly digested the tissues with which they had come in contact.

A VERY LARGE HEART.—Dr. Beverley Robinson presented two hearts, only one of which he was at liberty to publish the history of. The patient was a man of large build, being six feet and about five inches tall. He was a laborer, and had been a free drinker; for four or five years he had suffered from cardiac palpitation, dyspnoea, and insomma. He was treated by caffeine, digitalis, convallaria, etc., and by counter-irritation over the chest, which gave some relief. Some fluid was withdrawn from the pleural cavity on two occasions, after which the lungs expanded for a time. Afterward the breathing again became very difficult, the jugular veins were distended and throbbing, and it was decided to perform venesection. Fifteen ounces were withdrawn from the arm, the first eight of which were of a dark color, the latter part more normal in appearance. The relief was very great, and took place immediately; the engorged veins were no longer visible, but the relief proved only of short duration. The dullness over the precordial region, which had been present, extended, dyspnoea increased, and the man grew delirious and died. The heart was found to weigh 56 ounces. The largest which he had found on record weighed 46½ ounces.

The President said that Dr. Clark had presented a heart at the society which weighed, if he remembered correctly, as much as 57 ounces.

TYPHOID PERFORATION OF INTESTINE.—Dr. Robinson also presented this specimen, which had been obtained from a patient who died in a relapse of typhoid fever. The case had been of some interest because of the irregular course of the fever. Just before death the temperature dropped suddenly to 99°, probably at the time when perforation took place. The intestine was found perforated at two separate places.

Dr. Ferguson presented specimens obtained from a man in whom, at the autopsy, there were found hypotrophy with dilatation of the walls of the heart, the visceral and the parietal layers of the pericardium being covered with fibrin, brown induration of the lungs, congestion of the stomach and intestines, and the lesions of Bright's disease in the kidneys. The man had been addicted to the use of beer and whisky, was unmarried, twenty-five years of age, and had suffered from rheumatism; before death he had headache, dyspnoea, orthopnea, etc. He died delirious.

DISSECTING METEORIS.—Dr. Garrigues presented two specimens illustrating this affection, forming the last of a series of eight cases which had now come under his observation. The seventh specimen was obtained from a woman confined at the Maternity Hospital, in March last, with her third child. The head was extracted with the forceps. On the following day there was somewhat increased temperature. Intrauterine injections of a two-per-cent. solution of carbolic acid were employed, together with vaginal irrigation. Quinine and salicylate of soda were administered. Diphtheritic ulcers appeared at the seat of a slight incision of the perineum, and a suspicious spot was recognized on the anterior lip of the cervix, which was cataractized, and the carbolic solution was used. The next day the patient was delirious. Boric acid, ice-bag, etc., constituted the further treatment. A piece of flesh, about seven by two centimetres, was discharged, which proved to be a piece of the lining muscle of the uterus. After the expulsion of the mass the patient made a rapid recovery. The eighth case was that of a woman twenty-three years of age, primipara, who was delivered September 15, 1883, the labor being normal. There was a slight rupture of the perineum, which was touched with the tincture of iodine. The vagina was syringed with a one-and-a-half-per-cent. solution of carbolic acid. The next day the patient complained of pain in the abdomen, the lochia were profuse, the temperature was slightly elevated, and the uterus did not contract properly, and was sensitive to pressure. On the 16th of October she sat up for the first time; a pear-shaped body, about seven by four centimetres, was discharged, doubled upon itself, and found, as in the other case, to be composed of uterine muscular tissue—single fibers undergoing fatty degeneration, interspersed with small round cells, the sinuses being filled with fibrin. Besides the eight cases which he had observed, Dr. Garrigues had been able to find but two in literature.

MEASLES COMPPLICATED WITH CAPILLARY BRONCHITIS.—Dr. J. LEWIS SMITH presented a specimen, removed from a child which died in its fifth year. It had measles, which progressed favorably, but afterward laryngeal symptoms developed, breathing became obstructed, and the patient sank and died. Although the voice had been lost, no pseudo-membrane existed; there was intense laryngeal and tracheal congestion, extending also down into the bronchial capillaries. When this complication occurred with measles, the cases proved as fatal as those of scarlet fever.
OBSTETRICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held November 1, 1888, the President, Dr. R. A. Cleeman, in the chair.

Dr. B. F. Baez related the following cases:

FORCES LABOR, FIFTH POSITION.—On October 17th I was requested by Dr. ——— to visit his patient, Mrs. H., who had been in labor thirty-six hours, prepared to perform craniotomy. She was a primipara, forty-three years of age. I found the patient nervous and exhausted, the soft parts dry and rigid, the os only partially dilated and the membranes ruptured many hours. The head, a large one, was in the cavity of the pelvis, and, while not impacted, it was nearly so. The larger portion of the head was posterior and to the left, the smaller portion anterior and to the right. The fetal heart-sounds were heard in the left lumbar region and nowhere else. I therefore diagnosed a left occipito-posterior, or fifth position of Baudelocque. I placed a vectis, and endeavored to assist rotation forward, but failed to make any impression. I next adjusted, with some difficulty, Simpson's forceps, and, by traction during uterine action, with gentle efforts at rotation, allowing the forceps to turn as the occiput rotated anteriorly, that process was finally accomplished in about two hours of hard work. I now removed the blades, and, after finding that the head could not be extracted without it, I readjusted the instrument and assisted in extension of the head, extracting a living child said to have weighed twelve pounds. There was no laceration of the perineum. Both mother and child have done well. The case is interesting because of the age of the primiparous patient, and in the position of the occiput, which is rare.

ARM PRESENTATION; PODALIC VERSION.—On October 23d Dr. ——— requested me to see a patient with him, a girl sixteen years of age—a primipara at full term—in labor about twenty-four hours, the trunk presenting. In general appearance she resembled more a child of twelve than a girl of sixteen. The external genitals and vagina were small and undeveloped. The abdomen was greatly distended, globular, and fluctuating. Palpation was of only negative diagnostic value, probably on account of the large quantity of amniotic fluid. But I thought I detected the head in one iliac fossa and the breech in the other. Auscultation revealed the fetal heart-sounds, feebly heard in the right iliac region. The upper portion of the vagina was distended by a large, protruding "bag-of-waters," and the os uteri was fully dilated. I could only slightly touch the presenting part, which was entirely above the superior strait. I detected what I thought to be a limb, and, from what I had learned previously by inspection, palpation, and auscultation of the abdomen, I believed it to be an arm. I then dilated the orifice of the vagina preparatory to passing my hand, should that be found necessary after rupture of the membranes, which I now did, and found a shoulder presenting and an arm on the verge of passing the os. This I arrested, and made version by the feet. I preferred this version by the vertex, because I deemed it easier and less dangerous to both mother and child to effect delivery in that manner than to apply the forceps in this special case. The child was alive, but feeble. The body passed through the narrow vagina very slowly, and only after pressure on the fundus of the uterus, until the head reached the floor of the pelvis. Here, by assistance, the occiput rotated forward and the head was arrested. Flexion of the head could not be made to occur by supra-pubie pressure, and by pressure upon the nape of the neck, while a finger or two acted upon the anterior surface of the head through the rectum. I then quickly adjusted the forceps, and, carrying the handles forward with the body of the fetus, made flexion and extracted a living child. There was not the slightest laceration of the perineum. The uterus did not contract well; and, although ergot was administered, and time given for the organ to recover its tonicity (thorough kneading being used meanwhile), when the placenta was expelled a smart post-partum haemorrhage followed. This was easily controlled by the application of pure vinegar to the cavity of the uterum, injected by means of the long-nozzled uterine syringes, which holds about half an ounce. I prefer this method of introducing the vinegar to any other, for the reason that it is more easily and thoroughly applied. I carry the nozzle, guided by the index-finger, as in the introduction of the sound, into the uterine cavity, and project the vinegar, without force, over the surface. This can be repeated if necessary, which is seldom. Too much praise can not be accorded Professor Penrose for his earnest advocacy of the use of vinegar in the treatment of post-partum haemorrhage the result of uterine inertia. In my experience, it has always secured firm and continuous contraction, when properly applied. It is simple, antiseptic, and harmless.
Breech Presentation.—Twenty-four hours later, on October 20th, my friend Dr. W. L. Taylor requested me to see with him Mrs. X., a primipara, thirty-five years of age, who had been in labor twenty-four hours, the breech presenting in the left sacro-posterior position. The membranes had ruptured twelve hours previously, the os was rigid and only slightly dilated, and the breech was impacted in the superior strait, which seemed to be narrow. The patient was short of stature, fat, and had a small vagina. It was thought that the child was dead, but of this we were not sure. Was there any use in waiting longer for nature to effect delivery? We decided that there was not, and, I believe, correctly. An attempt at traction was made by acting on the thigh, but it was futile. I passed my hand with great difficulty into the cavity of the uterus, which closely surrounded the child, and endeavored to reach a foot, but found that the legs were extended, and it was only after I had advanced my hand absolutely to the fundus of the uterus that I secured the desired member. The uterine cavity was now so rigid and full that it appeared impossible to flex the leg and extend the thigh. But here perseverance again succeeded, and the leg was brought into the vagina. Delivery was finally consummated by the greatest effort. The child was dead, and, from appearances, had been so for some hours, as Dr. Taylor had suspected. The mother recovered as well as on an ordinary labor.

Puerperal Convulsions.—A few days before, October 21st, there entered my service at the Maternity Hospital a girl, eighteen years of age, illegitimately pregnant, and near term. She presented a depressed appearance, and was pale and puffy from edema. Her urine was examined at once, and found to contain a large quantity of albumin and some casts. Her labia minora were so edematous that she walked with difficulty. She was placed upon a treatment consisting of Basham's mixture, digi- talis, laxatives, and warm baths, with good food. On the 20th the nymphae were so greatly distended that I feared obstruction to delivery, which was about to take place; I therefore made about a dozen small punctures over their surfaces. This was followed by a very free discharge of serum, so that in the evening the labia were reduced more than one half. During the night labor occurred, and she was delivered naturally at 7 A.M. on the 21st, having been attended by my assistant, Dr. J. P. Pyle. There were no symptoms during the labor nor immediately after it to attract attention, but before leaving her he administered thirty grains of the bromide of potassium as a safeguard. At 9 o'clock he was hurriedly called, and found her just recovering from a convulsion. He at once sent for me, and began the administration of chloroform. But before I reached her, at 10 o'clock, she had had two more seizures, and just as I entered the room she went into another, which was one of the most terrific convulsions I have ever witnessed. I immediately opened a vein and allowed about sixteen ounces of blood to flow. I will confess that I did not want to take blood from this patient, because she was in such an apparently low condition. The bleeding did not seem to have the slightest effect, for very soon after it she had another convulsion fully as severe as the one preceding. Since the first attack there had been given, per rectum, twenty grains of the hydrate of chloral and forty grains of the bromide of potassium, and, per os, one fourth of a grain of elaterium. But the convulsions continued to recur, unless the patient was kept constantly under chloroform, and coma was deepening with each attack. I now injected, hypodermically, three fourths of a grain of the sulphate of morphine. This was at 11.30 A.M. She did not have another convulsion, although no more chloroform was administered until 2 P.M. At this time she had a slight one, and at 2.20 another much more severe, when I repeated the dose of three fourths of a grain of morphine. After this she had no more convulsions. The dose of elaterium was now repeated, and the kidneys stimulated by large doses of saline diuretics, administered by the rectum. The bowels moved freely and repeatedly soon after the last dose of elaterium was given, and the kidneys responded promptly; but the urine became nearly solid, when the test for albumin was applied, and casts were so numerous, and of such a character, that an unfavorable prognosis was pronounced by the competent microscopist who made the examination. The patient, however, came gradually out of the profound comat, but did not recover consciousness until nearly three days had elapsed, becoming at times wildly delirious and maniacal. As soon as she could swallow I resumed the administration of Basham's mixture and digitals, and on the next day added quinine and ergot, the latter especially to restore tone to the capillaries, and thus assist in improving the condition of the brain. Milk and beef-tea were given largely. The patient will leave the hospital to-morrow, although her urine still contains albumin in considerable quanti- ty.

If uræmia is ever the cause of eclampsia (which is not settled), this case presented the kidney state which is usually found in cases said to be of that origin. Since it is a-propos, I will relate a case which was probably not of uræmic origin, because the urine did not indicate the slightest disease of the kidneys.

My friend, Dr. J. B. Deaver, asked me to assist him in the delivery and treatment of a case of convulsions. The patient was eighteen years of age—a primipara, and unmarried. The opisthion was posterior and in the hollow of the sacrum. The first convulsion occurred after the head had passed the superior strait, and it was a very severe one. Dr. Deaver immediately bled, and very freely. Another convulsion occurred soon after the bleeding, although chloroform was administered and chloral given by the mouth. When I reached her she had had three attacks, and was profoundly under the influence of the anaesthetic, and, of course, could not converse in that state. I adjusted the forceps and delivered with the opisthion posteriorly, being unable to rotate it anteriorly. The anaesthetic was now removed, and not long after another violent convulsion occurred. I now injected two thirds of a grain of morphine under the skin. She did not have another seizure, and made an uninterrupted recovery. As stated above, there was not the slightest evidence of disease of the kidneys, either before or after labor. The cause here was reflex, the patient being predisposed by a depressed mental condition, etc.

The first indication to be met in the treatment of puerperal eclampsia should be to control the convulsions. I do not think it will be gainsaid that the prognosis becomes less favorable with each recurrence. I believe that morphine, administered hypodermically in a large dose, and repeated, if necessary, is one of the most efficient, if not the most efficient, means which we possess for that purpose. In the next case which I am called to treat I shall give one grain. I will bleed, if I think it is indicated, and shall use chloroform; but I will certainly give the morphine. I will then attempt to elimination through the bowels, kidneys, and skin. Dr. Clark, of Oswego, N.Y., first brought the morphine treatment before the profession in a fear- less and excellent paper, published in the "American Journal of Obstetrics" for January, 1880, which is worthy of study.

Dr. Elliott Richardson thought the extent of dilatation of the cervix a very important point in considering the advisability of version in shoulder presentations. When the fetus was in a transverse position it could not descend, and, as the cervix dilated, it would slip upward on the neck and chest of the child, and thus put the vagina in a condition of longitudinal tension, and, consequently, of narrowing. Any sudden or extreme attempt at dilatation of the vagina, when in this condition, in-
volved a great risk of laceration. In Dr. Baer's case the narrowness of the os uteri was a favorable circumstance for podalic version.

There was a wide difference in the treatment of puerperal convulsions between this country and Germany. Carl Braun strongly disapproved a bleeding, and recommended chloroform, with the administration of benzole and nitric acids, to assist the action of the kidneys. He considered that the prime object was to put the body at rest.

Dr. W. T. Taylor thought that in the second case, if the method of Dr. Wright, of Cincinnati, for the correction of the shoulder presentation by converting it into a vertex had been tried, the difficulties and dangers of a version by the feet might have been avoided.

He did not think bleeding should ever be omitted in the treatment of puerperal convulsions in pethlophatin patients. Bleed freely, and give chloral in large doses by the rectum. He thought the use of opium should be preceded by bleeding.

Dr. Alfred Wehlen had tried one fourth grain of nitrate of pilocarpine hypodermically after bleeding, the result being successful. The use of the pilocarpine did not seem to be followed by serous effusion. In one case in which no treatment of any kind had been used an autopsy showed all the serous cavities filled with effusion. He thought the arterial tension consequent on the convulsions was the cause of the exudation.

Dr. R. A. Cleman had tried all plans, and none of them were certainly successful; every method would fail at times, and any method would be followed by recovery. He thought bleeding should be tried in every case to remove the vascular tension, which was the great source of danger.

Dr. B. Trautmann had had under his care a primipara, pethlophatine, who was suffering from puerperal convulsions. She was bled, a large dose of calomel was given, chloral was administered, and pilocarpine was injected, but all without effect, the patient died. In another case the urine contained fifty per cent. of albumin, with casts, and no convulsion occurred. What was the relation between albuminuria and convulsions? Was the origin of the convulsion in the nervous system, and the albuminuria a result?

Dr. H. F. Beates remarked that, the presence of urea in the blood being generally considered a prime factor, most of the forms of treatment had reference to its elimination. Bleeding should be very free to act in that manner, and if it was prompt and free it would be followed by improvement; pilocarpine acted as an inhibitor of urea by the skin, thus relieving the kidneys and the system. He had treated two patients by this method, and both had recovered.

Dr. Philip M. Schieder had recently had under his care a primipara, aged twenty-five years; she had convulsions for four hours; chloral and bromide of potassium had been given freely, but with no effect; a hypodermic injection of three quarters of a grain of morphine sulphate was followed by quick relief. She was very pethlophatine, but there was no need for bleeding after the use of the morphone.

Dr. Baer, in the second case, had considered version by the vertex, but thought that he could deliver more quickly and with less danger to both child and mother by means of podalic version. He considered elimination a false principle in the treatment of puerperal convulsions. First stop the convulsions, eliminate afterward, if there be any necessity for it. How much elimination could be effected by drawing twenty or even forty ounces of blood? The majority of these patients needed all of the blood they had; they had none to spare. There was a neurasthenia at the bottom of these attacks. The patients were generally nervous and depressed from circumstances connected with their physical and social condition. Dr. Penrose, in his lectures at the University, taught blood—bleed; every patient that was bled sufficiently got well, every one that was not bled died. Dr. Carson's lecture followed immediately after that of Dr. Penrose, and he was as bitterly opposed to bleeding as Dr. Penrose was enthusiastic in its advocacy. He (Dr. Baer) had been afraid of pilocarpine, because its action, once established, could not be controlled. He thought, however, the effusions observed had been caused by the convulsions, and not by the remedy. Morphiine, used hypodermically, was the remedy upon which he put dependence; it would control the convulsion. Any medicine administered by the mouth or rectum must be of slow and uncertain action, because of the slowness of absorption from the alimentary tract.

NEW YORK SURGICAL SOCIETY.

(Concluded from page 556.)

NEW INSTRUMENTS.—Dr. Weir exhibited several new instruments designed to aid in controlling haemorrhage during operations. Among them were Tait's and Esmarch's fore-pressure forceps, Jouillard's forceps for removal of goitre, and a ligature-carrier of his own device.

COMPOUND FRACTURE OF THE THIGH AT THE JUNCTION OF THE SHAFT WITH THE LOWER EPiphysis: AMPUTATION.—Dr. Post presented a specimen with the following history:

September 16, 1883, I was called to see W. D., a boy eight years of age, in consultation with Dr. Lathrop, of Waltham, and Dr. Van Winkle, of this city. About two months before I was called to see him he was with his father's family in the country, and, riding in a wagon, his left knee was caught between the spokes of a wheel and violently wrenched. The result was a fracture of the thigh at the junction of the shaft with the lower epiphysis, the end of the shaft projecting through an extensive wound on the outer side of the knee. The severity of the injury was such that Dr. Lathrop, who was called in, recommended immediate amputation; but the parents would not consent. The patient was brought to town the day before I was called to see him. I recommended that he should be etherized, and the limb be thoroughly examined.

17th.—The patient was etherized. The limb was much swollen from the middle of the thigh to the foot. There was an extensive wound on the outer side of the knee, through which protruded the end of the shaft of the femur detached from the epiphysis, and in a state of necrosis. Sinuses extended through different parts of the thigh, leg, and foot. There were sloughs over the sacrum and over the heel. The posterior part of the os calcis was exposed and carious. Portions of the shaft of the tibia and fibula were exposed and rough, indicating superficial necrosis. The anterior extremities of the astragalus and cuboideal were exposed and rough. Several of the other tarsal bones were in a similar condition. The patient was very pale and emaciated, but his appetite and digestion had been pretty good. I performed amputation in the middle of the thigh. The incision passed through the upper end of an abscess, through which a finger could be passed up four or five centimetres. The operation was well borne, and very little blood was lost. The wound was thoroughly washed with carbolic acid, 1 to 40. A tent was introduced into the suppurating cavity, and the edges of the wound were brought together with sutures. Absorbent cotton was applied, and pressure made with a roller bandage. On examining the limb, the epiphysis was found in situ, but eroded, and almost demodified of cartilage. The head of the tibia was in a similar condition. The knee joint was disorganized. The medio-tarsal articulation was open; the cartilaginous sur-
faces of the astragalus, euloid, navicular, and two of the cuneiform bones were eroded. One of the cuneiform bones had been discharged.

18th.—The patient was troubled with vomiting after the operation, and he has not regained his appetite. He has slept for a number of hours; his pulse is steady, and not very feeble. Directed milk with arrowroot, and a little brandy, as the patient can be induced to take it.

19th.—Dressed wound and removed several of the sutures. Patient has moderate diaphoresis, but no vomiting. Ordered paregoric, p. r. n.

21st.—Dressed wound again; the edges have receded at lower part. Removed all the sutures; washed wound with carbolic acid, 1 to 40. Applied carp. adhes. and bandages to close wound. Diaphoresis continues. Ordered mistura cretae with t. op. camphor.

25th.—Decided improvement in general condition. Wound granulating.

October 3d.—Wound rapidly healing. General health steadily improving.

SUPPURATIVE FIBROID TUMOR OF THE UTERUS, WITH BOTH OVARIES AND STUMP OF THE UTERUS, REMOVED BY LAPAROTOMY.—Dr. Bull presented a specimen, and related the case. A single woman, aged thirty-four, was admitted to his service at St. Luke's Hospital, in August of this year, with a history of frequent backache, dragging pains in the lower part of the abdomen, and vesical tenesmus for three years previously. Menstruation was regular. In the middle line of the lower part of the abdomen was a smooth and rounded tumor as large as a child's head, plainly felt above the pubes and in the cul-de-sac of Douglas. It was movable, not tender, and apparently cystic. The uterus lay in front of it, and was antverted and thrown over to the right, where the fundus could be felt through the abdominal wall. Dr. Bull had seen the woman six months before, when the tumor was no larger than an orange, but, Dr. Thomas and Dr. Hunter having advised against an operation, he had decided to wait. On her entering the hospital again, Dr. C. S. Ward agreed with Dr. Bull as to the advisability of an operation, which was performed on August 14th. After exposing the tumor by an incision five inches long, adhesions were found to the ovaries and uterus. A double silk ligature, carbolized, was passed round each broad ligament. The uterus, just above the vaginal junction, was first temporarily constricted with an écraseur, and the tumor cut off an inch and a half beyond this. The pedicle (uterus) was then transfixed and tied with carbolized silk, cut off again half an inch beyond the silk, rubbed with iodiform and returned. On the left side of the pelvis the torn surface of the broad ligament bled. One silk ligature was applied and the surface was rubbed with iodiform. The sutures were removed on the fifteenth day. The temperature ranged between 98° and 99.5° F. On the second, third, and fourth days there was vomiting, with slight abdominal pain and tympanyes. The tumor was examined by Dr. Ferguson, who reported that it was a fibro-myxoma, subperitoneal, springing from the posterior surface of the uterus, about equally from the body and the neck. The ovaries were normal in size, the left containing two small cysts. The uterine body was slightly enlarged and laterally flexed. The neck, above the point of section, was elongated. The mucous membrane was normal.

Dr. E. L. Keyes exhibited the different kinds of forceps employed by Sir Henry Thompson for the removal of tumors from the bladder.

The Sanitary Institute of Great Britain will hold its annual congress in Dublin next year.
addition to the history of the operation. The summary of the tables is as follows, in the author's words: "Uterine displacement unchanged in sixteen cases. Uterine displacement improved in eleven cases. Uterine catarrh unimproved in ten cases, and improved in eleven cases. Subjective symptoms unimproved in three cases, and improved or entirely relieved in sixteen cases. Nutrition improved in eighteen cases, and remaining unchanged in five cases. Other treatment was found necessary in twelve cases." If "simply closure of the laceration, nothing more," be, as the author says, the direct result of this operation, it would find very few advocates. [In this radical expression we beg to differ with the author, though we believe with him that those who expect the operation will necessarily cure retroversion and cervical catarrh are over-confident.] His statistics, in a fifth table, as to the positive effect of the operation in curing sterility, are of value, though they must be verified by a much larger number of cases in order to carry conviction to the minds of doubters. His description of his needle-forceps and its method of use does not convince us that they are so simple as he would have us believe. The following statement, too, seems quite remarkable: "My assistants now are inclined to regard an operation a manipulative failure, no matter how many natures are required (italics are ours), that exceeds twenty minutes in length." Finally, the author recommends operation without any preparatory treatment, upon the ground that the operation is only preparatory and subsidiary to other treatment. [Another assertion which is, we think, too sweeping and misleading. Emmet's conservatism in enjoining such preparatory treatment as shall remove all tenderness in and around the pelvic organs is, doubtless, one great cause of his excellent results. Tenacity in this operation is not to be recommended when it renders pelvic cellulitis more than probable.]

Pithomata.—Dr. H. C. Yarrow ("Am. Jour. of Obstet.," August, 1888), in reporting this case, calls attention to the rarity and the peculiarity of the condition. The patient was a negro, forty-six years of age, who was supposed to be pregnant, and to have gone four months beyond the ordinary time for the termination of that condition. Resonance was obtained over the entire extent of the abdominal tumor, upon percussion, and auscultation failed to reveal any indication of pregnancy. The author was called in consultation, and happily diagnosed the condition as that which is mentioned in the heading. A speculum was introduced into the vagina, and through it a sound was carried into the uterus, traversing the cervical canal and internal os with some difficulty. The result was an immediate collapse of the abdominal tumor, the escaping gas being odorless, and passing out with great force. A lengthy narration of cases covering the literature of the subject follows, and the conclusion reached is that this condition, or typanumus uteri, is due (1) to the presence of some decomposing substance in the uterine cavity; (2) to an impediment to the escape of the gases of decomposition.

The Development of Uterine Myomata.—Kleinwächter ("Ztschr. f. Geb. u. Gyn.," ix, 1) informs us that the precise steps in this process are not yet fully known. There is a transformation of round into spindle cells which can not be distinguished from organic muscular fibers, but that there is hypertrophy to any extent on the part of the muscular fibers themselves is not probable. It is difficult to say whether the round cells take their origin from connective tissue or from divisions of the cells of muscular tissue. In making his investigations, the author found that small growths were much better suited to his purpose, since in the larger ones either the process of development was completed, or the particular points were hard to find at which it was still incomplete. The specimens studied were either myomata or fibro-myomata, pure fibromata being never found by him. They were usually subserous and multiple, in many cases were located upon the fundus uteri, less frequently upon its posterior aspect, or upon the lower segment of the body, and exceptionally upon the anterior wall. Wherever the growth projected from the body, it was usual to find the peritoneum somewhat thickened. The bundles of muscular fibers crossed each other in all directions, and were very compactly arranged. The dimensions of the cells and their nuclei were somewhat greater than is customary in the ordinary muscular fiber of the normal unipregnated uterine. The form of the growths was usually spindle-shaped, with a tapering pedicle extending from one side. The capillaries were usually abundant and large, but there were few arteries and veins. On both sides of the capillaries were rows of round cells, which in many cases formed a sort of covering. These round cells seemed gradually to take on a spindle-shaped appearance. As this development progressed the capillaries were gradually obliterated, until at length, in place of several vessels, there would appear only a bundle of muscular fibers. The pedicle usually disappeared in the neighboring connective tissue, suggesting that the tumor had developed from such a point. In the multiple form of this growth each separate tumor had its own capsule, or else a strong layer of normal muscular tissue, for a covering. A new development of vessels was observed in fibro-myomata, but never in myomata.

Extermination of the Cervical Uterus.—The "Med. Times and Gazette" (May 5, 1883) abstracts from the report, in a recent number of the "Archiv für Gynäkologie," of the Medical Congress at Eisenach, in September, 1882, certain data with reference to this subject, of which the following is a summary: Obshausen had performed the operation per vaginam successfully twenty times, with fourteen recoveries. In nineteen of these cases the cervix was diseased, and in three the body of the organ. In one case a myoma upon the posterior wall of the cervix was mistaken for cancerous disease. Of those who recovered, one died in fifteen months after the operation, another in seventeen months, both from a recurrence of the disease, and in a third the disease had recurred, but the patient was living at the time of the report. In three other (additional) cases Obshausen had attempted to remove the organ by the same method, but had failed on account of adhesions to the rectum and bladder. Martin, of Berlin, reported that he had attempted the same operation in thirty-one cases, in five of which it was incomplete. Two of the incomplete operations were fatal, and four of the complete. Within a year and a half the disease had recurred in all the survivors, with one exception. Sänger, of Leipzig, reported two successful operations. One of the subjects died from recurrence in ten and a half months, the other had been operated upon only a few weeks before the report.

Oophorectomy.—Tauffer ("Ztschr. f. Geb. u. Gyn.," ix, 1) makes his experience and observation the basis of the following propositions: 1. With proper precautions the operation is not attended with great danger. The unavoidable mortality is now less than ten per cent. 2. The operation should be done with antiseptic precautions, and under the carbolic-acid spray; the abdominal cavity should be closed, drainage being necessary only in exceptional cases. 3. Since the time for the climacteric is not a fixed period, the age of a person, with reference to the climacteric, is not to be considered in all cases. 4. Hugr's proposition, that palpaton of the ovaries must be possible in cases which are to be operated upon, is impracticable. 5. Both ovaries should be removed, excepting in cases in which peculiar circumstances demand the retention of the second undissected ovary. 6. The tubes should also be removed if they show the slightest evidence of disease. 7. Hystero-epilepsy is curable by castration. 8. The symptoms which, collectively, are known
as hysteria, are often attributable to ovarian disease. The question as to the influence which ligation of large nutrient vessels will exercise upon uterine fibro-myo-somatosis, without castration, is well worth consideration. 10. The clinimetric will, as a rule, quickly follow the operation, excepting in cases in which inflammation has attacked organs contiguous to the ovaries. In case of such accidents the clinimetric is usually delayed. 11. Many months may elapse before the ultimate value of an operation can be estimated. 12. The question as to the influence of diseases of the female genital organs upon the development of certain psychoses is an open one. 13. The same may be said of the question as to whether castration will cure such psychoses. 14. In contributions to the clinical literature of this subject, it is desirable that the cases be grouped under such a plan as was proposed by Hegar, or something which resembles it.

Miscellany.

Theorapeutical Notes.—Anaesthetic Mixtures.—M. Guilhot, a dentist of Lyons, France ("Progrèss médical," October 15, 1883), gives some points in his personal experience with various anaesthetic mixtures. He has experimented with several of them in the dental clinic at Gènes, and in his own private practice, with a view to obtaining an anaesthetic that should be safer than chloroform and more prompt in its action than ether—in short, one that should present as many as possible of the advantages, and as few as possible of the disadvantages, that attend the use of anaesthetics. In 1877 the Odontological Society of London appointed a committee on anaesthetic mixtures. That committee experimented with three such, the formulae of which are as follows: 1. Alcohol, one part; chloroform, two parts; ether, three parts. 2. Chloroform, one part; ether, four parts. 3. Chloroform, one part; ether, two parts. Dr. Guilhot obtained the best results from the first, a combination which had been proposed by Dr. Harley. The physiological effects of the second were almost identical with those of simple ether. The third had an action intermediate between the action of chloroform and that of ether. A mixture proposed by Lennox Browne proved, however, superior to either of the three foregoing. It consisted simply of one part of alcohol and two parts of chloroform. This was more active than the first mixture above mentioned. It was of great service in extracting the teeth of children who were apt to be frightened by the apparatus used for the administration of nitrous oxide gas. In order to make his mixture more agreeable to the patient, Browne replaced the alcohol in it with eau de cologne. This combination was called "chloroacérine." Its action was rapid and very satisfactory. It was administered in a large number of cases at the dental clinic, for a period of four years. Numerous patients who had taken it were interrogated as to the sensations it produced. None of them complained of the nausea or disagreeable feelings in the head that follow anesthesia from ordinary chloroform. Dr. Sanson is said to have proved that the alcohol mixed with the chloroform has a very valuable sustaining influence on the heart. A frog that he had anaesthetized with the alcoholic mixture "could not perish, although he pushed the anaesthesia to the last degree." Moreover, he avers that the administration of alcohol by the stomach has by no means the same sustaining action on the heart.

Dr. Guilhot's method of employing "chloroacérine" is as follows: A small napkin is rolled into an inhaling cone, an opening being left, however, at the small as well as at the large end. The proper shape is maintained by the use of pins. Two grammes of the mixture are poured upon the lower part of this inhaler. After inhalation has gone on one minute, two more grammes are poured on the napkin. After another minute's inhalation, the opening at the top of the cone is closed for thirty seconds to prevent the entrance of air. At the end of the half-minute the patient is ready for operation. His mouth is opened and the extraction of the teeth is accomplished. If it is desired to perform a longer operation, the inhalation may be continued. "Chloroacérine" has been used successfully in the removal of a good-sized tumor of the lower jaw. Dr. Guilhot has never met with any accidents in the use of this anaesthetic mixture. Its use elsewhere has been unaccompanied with loss of life.

The Administration of Quinine.—Dr. David Young, of Rome (Italy), is of the opinion ("Practitioner," October, 1883) that quinine is too indiscriminately administered in cases of fever, particularly in fevers which, occurring in malarial regions, are to be more or less malarial in their nature. In such regions practitioners are too apt, he believes, "to give the benefit of the doubt" to almost any acute disorder ushered in by a chill and accompanied with a rise of temperature, and to treat such cases tentatively, in their early stages, when exact diagnosis is often impossible; with antipyretic doses of quinine. While such practice may be to a certain extent necessary and justifiable, he believes it to be unjustifiable unless the physician exercises more than ordinary discrimination in persisting with the quinine treatment. Without such discrimination, he is satisfied, from eleven years' experience in a malarial city and region, not only that the quinine may fail to do good, but that it may prove of the greatest harm. He details his typical cases which began, to all appearances, as malarial fevers. In one, quinine treatment aggravated the symptoms and death took place on the third day. In the other, the symptoms grew steadily worse while antipyretic doses of quinine were administered, until a condition quite like that in delirium tremens was set up. A change of treatment to two-grain doses of cabanol, to the head, and Apollinaria water was followed by gradual but complete cessation of the symptoms that had been alarming. (The case proved to be one of typhoid fever and ran its course. The patient made a good recovery.) From these cases Dr. Young concludes: 1. When the bowels are confined and the urine is scanty, antipyretic doses of quinine should not be given. 2. In cases where quinine is being given, and an increase of dose is thought to be desirable, such increase is safe if the skin, bowels, and kidneys maintain their functional activity. 3. During the administration of quinine, should a headache come on or increase in intensity, the case requires the most careful attention. Many physicians advise their patients who are about to travel in Italy to begin a regular course of quinine as soon as they cross the Italian frontier. This, in Dr. Young's opinion, is a pernicious practice. A considerable number of English and American tourists suffer from actual chills as a result of their following this well-meaning but unwise advice. Moreover, although both remittent and intermittent fevers appear to arise from the same cause, and although they present similar clinical features, and may even alternate and replace each other in the same individual, there is, nevertheless, a great difference in their respective behavior toward quinine. Quinine is a better prophylactic against intermittent than against remittent fever. Furthermore, while quinine maintains its curative power over cases of purely intermittent ague for a long period, its efficacy in remittent forms of the disease is often quickly spent, and in some cases is not manifested at all. In Rome but a small proportion of tourists who suffer from fever are affected with the intermittent type.

Many patients have an idea that they can not take quinine at all. Such notions are sometimes encouraged by physicians. A large proportion, at least, of these patients will tolerate quinine if it is administered in combination with other drugs. The therapeutic relations which exist between certain remedies are of great importance, and deserve more investigation and consideration than they have hitherto received. Iron, for instance, with a saline, will often be well borne and produce good effects in cases in which, alone, it is not well borne. Cases of chronic intermittent ague will defy quinine and yield to arsenic, or, more curiously still, to Warburg's tincture, a preparation containing quinine in varying proportions as its chief ingredient, together with other apparently unimportant substances. Very many of the patients who have a constitutional antipathy to quinine, and believe therefore that they can not take it, are able to take the alkaloid if it is given with chlorate of ammonia or a salt of potassium.

Jodoform in Chronic Otitis.—Dr. David Prince, of Jacksonville, Illinois, has met with success ("St. Louis Medical and Surgical Jour-
The nurse should have instructions not to be afraid to give bran, if there should be signs of fainting from the violent action of the aperient."

The Brain GAUZE.—Among the interesting minor points touched upon at the recent meeting of the British Association was that of the relation and constant ratio existing between the size and capacity of the skull in different races, and the dimensions of the adult female pelvis. The conjugate diameter of the pelvic brim of the mother, it was explained, acts as a gauge of the potential brain-power of the offspring, by forbidding the passage into independent existence of any child having a skull, and therefore a brain, of disproportionate size. This is a broad and rational conclusion, and is fully borne out by the facts and figures regarding still-birth which have been placed on record by various observers. Thus it was shown by Sir James Simpson that the heads of male children measure, on an average, about half an inch more in circumference than those of females, and that, in consequence, a larger number of male than of female foetal skulls are denied passage by the maternal pelvis, causing a considerable numerical excess of male over female still-born infants. It has been shown also, with sufficient clearness, that, broadly speaking, the size and weight of the brain, and, therefore, the external measurements of the skull containing it, may be taken as a measure of the intellectual power of the individual. There is a philosophical interest attaching to these conclusions, which does not perhaps appear quite on the surface. The bony frame, or diameter of the maternal pelvis, is thus made to serve as a direct measure and means of limitation of the mental capacity. It follows that it is impossible that any race or family should so develop exaggerated or phenomenal brain-power as to cause a deterioration or puny caliber of the osseous and muscular systems. For, the pelvis becoming contracted and ill-developed as the brain and skull became overgrown, the former would gradually exclude the passage of the latter, and the over-intellectual race, with disproportionate cerebral power, produced at the expense of the physical forces, would rapidly become extinct. The converse of this proposition would hold equally good, and the large maternal pelvis, acting, as before, as the gauge of the intellectual power of the offspring, the mother possessing the best physical conformation would become the only possible parent of the son gifted with the largest cerebral development. Intelligent natural selection would lead thus to the choice by men of massive intellect (who might be desirous of reproducing their mental attributes in their children) of wives in whom the roomy and expansive physical type should afford the best chance of the large and highly organized foetal brain passing the gauge. It is perhaps to be regretted that the question of the improvement of the human race by a process of rational, as opposed to natural, selection is one more of theoretical philosophy than of practical possibility.—Med. Times and Gaz.

Sir James Paget on Recreation.—The address recently delivered by Sir James Paget at the Working Men's College, though treating of a subject pretty well worn, was so suggestive as to warrant us in reverting to it from a standpoint slightly different from that taken by us in our remarks last week. Sir James laid down what he considered the essential elements of healthy recreation—uncertainty, wonder, and the exercise of skill; and analyzed each, giving fitting examples. Mental fatigue may find its counterpart in mental or bodily exercise. The industrious student, often at the hour of midnight, lays aside his intricate mathematical problem, or record of disease, or involved legal argument, and turns with a sense of relief, not alone to indolent repose, but often to follow the development of an enchanting love story, or the word painting of such a novel as "Endymion." Or he takes up his
MISCELLANY.

Auburn American  

— But for—is conjectural.  

And New Jersey  

How differently does the dissection of a plant, or the clipping of a rock, seem under such circumstances.  

There is a certainly of acquiring knowledge—a certainly of sense, without the dread of failure at an examination.  

When Sir James speaks of the American marcelling at our hands, it recalls to our mind the pleasure that lit up the countenance of an American lady as she remarked, “There are two things in which you English beat us—your strawberries and green peas.” These things seem trifles in themselves, and yet they represent moments of relief in the days and hours of strain.  

It should be a part of the education of students to teach them how to play, and to place the means of harmless recreation within their reach.  

Chasis attached to our medical schools, debating societies, cricket, and football, are among the resources that go to lighten the labor which brings much enjoyment, but some necessary distress.  

The yearly holiday, or the vacation after term, is not enough; there should be an off-recurring alternation of work and play.—Lancet.

Access.—The rough autumn blast is strewing the fields with an unusually plentiful crop of acorns. So thickly studded is earth's grassy lap with this astringent harvest that one is tempted to inquire what purpose (besides the reproduction of the quercus genus) the acorns may serve in the economy of nature—to what use, medicinal or dietetic. It is not applied to man or beast; many parts of the country, near all rural districts, in fact, in which we have made inquiry, the subject, acorns are in common use by the rustic population as a medicine in diarrhea from whatever cause. A store of dried acorns forms part of many a country housewife's domestic pharmacopoeia, and the grated powder is administered with good effect in many cases of intestinal flux. Probably, since the acorn contains so very large a proportion of tannic and gallic acids, its operation in such cases is at least as beneficial as that of any tinctures of kino, catechu, catany, or other official astringent, administered by proper authority. Vast quantities of acorns, as we all know, are also greedily eaten by pigs, deer, and possibly other animals, who become fat and well-conditioned on this fare. It would be interesting if we could learn from some of our veterinary friends how it is that these creatures can live and continue upon a diet which, though it may contain some nutritive material, contains also so overhelming a share of tannic and gallic acids that even the porcine digestive apparatus ought theoretically to be brought to a deadlock by its use. Is it the fact, may we ask, that pigs, deer, etc., suffer occasionally from cotitie or obstructive troubles, by the drying up of the intestinal secretions as a result of a free diet of acorns at this season? And were it possible, may we ask again, to make any use of acorns, crushed or ground, as an admixture in the food of horses, especially those in whom a constant looseness or "scouring" makes sleek appearance and good condition almost an impossibility?—Med. Times and Gent.

Arterial Lesions in Viscose Ulcers.—The difficulty of interpreting the relations of associated changes constitutes one of the most beneficial exercises for the development of a logical state of mind. Cornill and Ravine have observed endarteritis frequently in the tissues of wounds, ulcers, and inflammations of the connective tissue. Some new investigations on varicose ulcers by MM. Aronson and Bonney have revealed a remarkable degree of change in the arteries of the parts bounding the ulcer. In the smallest vessels an increase in thickness of the muscular coat has been measured. In the larger arteries areas of endarteritis were discovered together with hypertrophy of the muscular coat. What is the sequence of events in such a varicose ulcer? Is the ulceration dependent on the arterial disease, or are the vascular changes secondary in point of time to the ulceration? Are all the changes the result of increased venous congestion, or is there some other cause at the root of the whole of the alterations?—Lancet.

VACCINATION ATTENDED WITH EXPERIENCES.—In England the majority of physicians are probably inclined to accept the views of Messrs. Cody and Bullocks that cow-pox and smallpox are the results of one disease and the same poison. But the matter cannot not theoretically be considered as finally settled; for the prevalent opinion in France seems to be in favor of the duality of the poisons of vaccinia and variola. M. Warlomont, however, a thoroughgoing germ theorist, does not follow the lead of the majority of his co mdbrems. He has reopened the question by ingeniously introducing into the discussion the latest teachings on the subject of attenuation. It is known, he argues, that artificial media are capable of effecting a progressive attenuation of the virus of bacteria, so that generations preserving this attenuation of the virulence of the poison may be cultivated. Just as this has been proved for the bacteria of scarlet, so it may happen to the germs of variola. Pushing the analogy further, M. Warlomont follows the stages of the modification of the virulent virus from man to horses and from horses to cows. It so happens that the mean temperatures of man, horses, and cows form an ascending scale, being respectively thus: 37°5, 38°25°, and 39° C. M. Warlomont therefore urges that the microbe of variola, in passing from the human organism to the system of the horse and then proceeding to that of the cow, would undergo a kind of forfeit similar to that which the bacteridia of malignant putrid fall suffer when cultivated in artificial boulion of which the degree of heat is purposely augmented. Science demands something more than mere ingenuity to establish the occurrence of such a conjunctural process.—Lancet.

LARYNGEAL CHEOREA.—What may take place over the whole body may occur in any portion of the anatomy. That seems to be the principle on which M. Blachez worked when he spoke at the Académie de médecine last week on what he chose to term chorea of the larynx. The affection had been observed in two boys, aged ten and six years, the children of parents with rheumatic history. The laryngeal disturbance manifested itself as a nervous cough, very like the horse barking sometimes met with in hysteria, of which condition, however, there were no other signs in the boys in question. We are familiar with the deep barking cough so frequently accompanying the ascension of the state of puberty, in the male sex more especially, but the above instances seem hardly to come within that category. The term consists seems so welded to the idea of a more or less general affection of the muscular system that it seems hardly justifiable to speak of a laryngeal chorea.—Lancet.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from November 10, 1883, to November 17, 1883.—BACHE, DALLAS, Major and Surgeon. Ordered to report in person to the commanding general Department of the East for assignment to duty. Par. 10, S. O. 239, A. G. O., November 12, 1883. ——GARDNER, J. de B. W., Captain and Assistant Surgeon. Relieved from duty at Fort Huachuca and assigned to duty as Fort Surgeon at Fort Bowie, A. T. Par. 1, S. O. 104, Department of Arizona, November 8, 1883. ——EOAN, Peter R., First Lieutenant and Assistant Surgeon. Upon being relieved from duty at Fort Bowie, A. T., to proceed without delay to Fort Huachuca and report to the commanding general that duty for duty. Par. 1, S. O. 104, Department of Arizona, November 8, 1883.

NAVAL INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending November 17, 1883.—Passed Asst. Surgeon SCHROEDER C. H. H. Hall ordered to the Naval Academy, Annapolis, Md.

IS CONSUMPTION COMMUNICABLE?

By JAMES R. LEAMING, M.D.,
Professor of Physical Diagnosis and Diseases of the Chest in the New York Polyclinic; Special Consulting Physician in Diseases of the Chest to St. Luke's Hospital.

From the earlier days of medicine to the present time there has ever been a popular belief that consumption is communicable. Such a widespread and general opinion, continuing for ages and in many countries, must have some foundation in fact. Cases of consumption have followed each other under circumstances which have impressed observers as proof of its infectious character; as when a husband or wife has watched with the deepest solicitude the long-continued and vacillating illness of the other, to be finally overwhelmed with grief at the fatal result, and then to sicken and die under similar conditions.

The profession has at times inclined to the popular faith, and again has rejected it.

The discovery of true tubercle by Bayle in 1804, and of the method and value of asculptation by Laennec, published in 1819, threw new light upon diseases included under the common name of consumption. It did more; it filled the professional mind with the idea of tubercle, to the exclusion of other and common forms of consumptive diseases.

The very important doctrines taught by Broussais, in Laennec's time, because they were not all of tubercle, were overshadowed, obscured, and misunderstood. The immense advantage of physical diagnosis by auscultation and percussion in getting a true mental picture of the pathological conditions of the chest was certainly weakened by the adoption of the exclusive doctrine of tuberculous.

The erroneous interpretation of the respiratory act and of the significance of its murmurs, as taught by Laennec and his followers, confirmed them in the pathological error that all forms of consumption must necessarily be tuberculous. But the fashion of careful post-mortem examination grew in favor, and the microscope vastly extended our knowledge of pathological results, and has established the fact that the tubercular is not the only form of phthisis. Still we are groping among the debris of protoplasm, cells, and proliferation, anxiously searching for the specific evidence of tuberculous as an entity self-existent and self-propagating—something which has a separate life from the life of the body, and which is independent of it, antagonistic to it, and which overcomes it.

This view differs from that which considers consumption, either tubercular or fibroid, as inherent in the life of the body, which is excited to activity by irritation or depression, either physical or mental.

It is said that the giant cell characterizes tubercle and the spindle-shaped cancer, and that by them we are able to distinguish tubercular and cancerous products. But this knowledge of them does not determine the life-producing origin of tubercule nor that of cancer; whether they have a distinct life outside the life of the body, and have only an accidental connection with it, or whether these morbid cell-forms are merely the materialized expression of disease-action of the immaterial life of the body. Animals have been experimented upon by inoculation of tuberculous matter, and tubercle has been the result, and it has been claimed that the question was solved in the affirmative. But, again, these same animals were inoculated with non-tuberculous matter, and the result was tubercle, proving that the character of the inoculated matter had nothing to do with the tuberculated results, but that irritation was the sole cause, and the result would be tubercle or cancer, according to the inherent tendency of the individual either to tubercle or to cancer. The irritation of telescoping endangers tubercular meningitis in children, and tuberculated phthisis may result from the irritation of adhesions of the pleura. Had not this theory of tubercular inoculation disestablished itself by these experiments, it would still remain an essential fact that inoculation is not infection, that poisoning the system by inoculation of any materies morbi is not conveying a germinating parasite into healthful respiratory organs, and producing disease in them of its own kind. But lately the medical world has been set wild by the publication of the discovery of Professor Koch of the presence of bacilli in tubercular cavities and in tubercular sputa.

It has been shown, too, by experiment that these independent life-forms may propagate themselves outside the body and in other menstrua than the debris of decaying tubercular cavities.

These facts appear to be demonstrated and accurately proved by other careful observers. But the deductions of Professor Koch are that these self-producing life-forms are the cause of tuberculosis and of tubercle, and propagate their kind in a healthful human lung, and, thence taking wings, are carried to and transplanted in other healthful lungs. Their propagation being rapid and abundant, and the medium of their conveyance the air we breathe, the danger therefrom becomes appalling to fearful minds, who dread the ravages of this most deadly of human diseases. To be entirely consistent, the germ theorists must deny the influence of heredity and external conditions, of local irritation or the depression of vital dynamics, as causes of consumption.

If it were not for the adoption of Professor Koch's theories, as well as the acknowledgment of his discovery of bacilli by gentlemen of high scientific attainments, such as Professor Rühle, of Bonn, and others, controversy would be unnecessary; but, as it is, we must examine the subject critically but dispassionately.

So far as I am aware, fibroid phthisis is not included in the forms of consumption claimed to be propagated by bacilli. The germ theorists appear to assume that all forms of phthisis are tubercular. But a large number of cases are fibroid, pure and simple, in which the disease is gouty or rheumatic, and not scrofulous. This large number are exempt from suspicion even. Again, a vast majority of cases of tuberculated phthisis commence with plastic exudation within the pleural cavity. These are called by Niemeyer
"cattarhal pneumonia," and he says "the great fear is that they may become tubercular." This fear is born of experience, and should direct us to proceed energetically, at the same time judiciously, to remove the plastic exudation while it is easy of accomplishment. Now, as long as the cases are not tuberculated nor tubercular, they can not be influenced by bacilli, for as yet there is no nest prepared for them. It may be well to state here that we make a distinction between tuberculosis and tuberculated phthisis. Tuberculosis is the systemic disease which gives birth to true tubercle—the mililiary tubercle of Bayle. Tuberculated phthisis is the result of cheesy degeneration, in which cavities take place as a result of tuberculosis or other causes. The number of uncomplicated cases of tuberculous phthisis—that is, of tubercle forming into concretions or nodules and being encapsulated, with no pleuritic adhesions and without fibroid in the lung, is extremely small. In a practice of more than thirty years in dispensary, hospital, and private, I can not remember more than a very few cases. Laennec and Louis evidently refer to these cases under the term of latent phthisis and acute phthisis.

This small number, commencing centrally in the lungs and not involving the pleura, are the only ones which could have had a parasitic origin. But even in these it is doubtful whether bacilli have anything to do with their tubercular origin.

I do not doubt the discovery of bacilli in tuberculous cavities nor in the spuza of tubercular consumptives, but I can not accept the inference that they are the essential cause of tubercle. They may find in a tuberculous cavity a fit soil or home where they may grow and multiply. There may be spores, eggs, germs, laid there by their parents, which, when perfected, may fly away to seek other tuberculous cavities in which to lay their eggs, etc.

Is there not analogy in the green-bottle fly that seeks carrion in which to lay its eggs, where they are hatched into maggots, which may increase the rapidity of the destruction of the carrion during their growth, but, becoming full-grown flies, they fly away to seek other carrion to plant their eggs, and thus continually propagate their race?

The bacillus of Professor Koch may be the maggot state of a distinct life, born of an egg or germ, and may perfect itself into another form which may fly away to find other tuberculous cavities, fit homes for the propagation of its kind, as germs, bacilli, and of the perfected life-form which will again fly away to find other tuberculous homes.

It is not probable, nor according to analogy, that the bacillus was always in that state, or that it will always remain as such, to be transplanted to healthful lungs and to cause tuberculosis; for it is not the disease, but a parasitic life which grows and perfects itself in the decay and debris of tuberculous cavities. It may increase the rapidity of decay in the necrosed lung, as the maggot does in the carrion, and it is our duty to prevent this if we have the knowledge and the power. But the bacillus is not necessary to explain the occurrence, cause, and course of phthisis—fibroid or tubercular. As has been stated, all but a very small number of cases commence as fibroid—that is, with plastic exudation within the pleura, in which the bacillus is not a factor. This primary condition of phthisis may be the result of depressed vital power from various causes, long-continued and violent emotion, anxiety, worry, grief, or disappointment, as well as from cattarhal causes. Or it may, but in a less degree, be the result of adhesions from acute pleurisy, which are a physical cause of vital depression.

A mother, after watching her children, three or four in number, through scarlatina of a severe type, began to cough, lose weight, and finally died of phthisis. She was well when the children were taken ill; she was a loving, anxious mother, and as they were attacked successively the time of her anxiety was prolonged. The children all recovered, but the mother was sacrificed. She was not aware of having taken cold. The cough was so insidious that no one could tell when it commenced. Had there been the same prolonged anxiety over a case of phthisis, followed by inconsiderable despair at the loss of the loved one, it would have seemed to prove the communicability of consumption. Scarlatina germs do not originate phthisis, nor do bacilli—it is the result of natural causes.

Failure in business after a prolonged struggle in a conscientious man may be, and frequently is, followed by phthisis. Disappointment in the young, where there is intensity of grief, is often followed by phthisis. In all of these cases, whether fibroid or tuberculated, the disease commences with plastic exudation within the pleura.

Even in tuberculous phthisis, for a considerable time the disease is simply fibroid—preventable phthisis.

One word for the poor consumptive. Morbidly sensitive to all unpleasant sights, smells, and surroundings, and whose greatest comfort is kind and sympathizing companionship, is it not the refinement of cruelty to drive away from him unnecessarily those who should minister to his suffering?

THE PATHOLOGY OF ACUTE LOBAR PNEUMONIA FROM A NEW STANDPOINT.

BY WILLIAM D. SCHUYLER, M. D.

Fifth Article.

The Process of Degeneration and Resolution.—The Verification of the Theory.

Sufficient arterial blood, is, however, still supplied by the bronchial arteries, the nutrient vessels of the afferent pulmonary structures, to sustain organic life and stimulate lymphatic action, and also to promote degenerate softening of the exudate, which, it may be stated, has been in progress since exudation first commenced. On account of the loosely combined and adhering character of this hemorrhagic exudate (which in common with any ordinarily formed coagulum soon separates into a more or less solid and a liquid portion), and being surrounded by the most favoring conditions of heat and moisture, its more complete degeneration, softening and final liquefaction now go rapidly forward.

One of the marked characteristics or features of this degeneration—seen at autopsy but impossible of recognition
SCHUYLER: THE PATHOLOGY OF ACUTE LOBAR PNEUMONIA.

Dec. 1, 1883.

595

excep inferentially during life, and therefore of no clinical interest, and of no pathological value except as denoting post mortem the degeneration of the exudate going forward—is a change of color, which the involved lung has undergone, from a previous brownish red (pathological) to a yellowish gray or more complete yellow.

Besides these degenerative changes which relate to the already formed exudate, and, with the exception of, in some cases, a new cell-formation, a development of epithelium from the alveolar structures at this time (not generally recognized by pathologists, but which occurrence is mentioned by Niemeyer, and, according to Rindfleisch, “forms the proper central point of the stage now following, yellow hepatization”), there are no new events to be mentioned as occurring in the solidified lung until such time as circulation is resumed through it.

That softening is going forward may be determined by the physical signs now to be obtained—namely: less perfect bronchial breathing and less perfect bronchophony, a returning rale, at first fine, then mixed coarse and fine (the coarse occurring later), the rale redux of this malady; a gradual redevelopment of the vesicular respiratory sounds with the decreasing bronchial—rather, broncho-vesicular respiration, decreasing dullness, and soon, in some localities, or beginning in one locality, the complete respiratory vesicular murmur with more or less normal percussion resonance.

When this degenerative softening with shrinkage of the more solid elements of the exudate has advanced to a necessary degree, and lateral pressure is thereby sufficiently removed from the compressed capillaries, they are again rendered pervious by the force of the remaining, general, systemic blood-pressure (acting throughout in the larger divisions of the pulmonary arteries which, resisting pressure, remained open), and circulation is resumed. The re-establishment of this function may occur very quickly throughout the region consolidated, or gradually, the rapidity of this event depending upon the condition of degeneration, whether it is evenly concurrent, or is present in differently advanced stages. Where an attack of pneumonia results in a rapid general consolidation, or comparatively so, as in what may be termed normal cases, degeneration of the consolidated will advance evenly, and the conditions for the resumption of circulation will be nearly or quite synchronous. In these examples such re-establishment is rapid, and is the cause, as I shall show, of that significant group of symptoms the occurrence of which marks and is recognized as the crisis of resolution.

If, on the other hand, owing to conditions of general debility rather than local, the development of the anatomical process is gradual in which successive areas, greater or smaller, not limited, become implicated in succession, degeneration accordingly will be more or less, relatively, varied, and resumption of circulation as a whole will be gradual. When it is gradual, resolution is not marked by a rapid abatement of symptoms, convalescence is more extended, and is then said to be by lysis. As the former mode of resolution is the more common in acute primary cases, it may in that sense be regarded, as before stated, as normal.

However, as the unlikeliness of the two recognized modes of resolution, by crisis and by lysis, is one of degree merely, and not due to an essential difference of cause, one requiring but a few hours to a day for its completion, while the second extends over one or more days to accomplish the same process, their manifest difference is not one of character, but of time only.

Resolution and removal of the consolidate by absorption and expectoration go on rapidly after crisis; and generally in the course of three days to a week; or thereabouts, the local signs, excepting slight dullness which may persist for weeks, disappear. And also, aside from an impaired respiration and a somewhat predisposing tendency to recurrence in some subjects, and in others a consequent general debility, the patient is as well as before the attack. If he is better than before, it is probably the result of altered conditions, which would as well have resulted from like treatment, less the pneumonia pathological element as a cause.

The above concludes a rational exposition, as I maintain, of the formation of the local anatomical process of this malady. It sets forth my theory of its initial lesion, and gives in order, as the unavoidable consequences of this lesion, and the vitally necessary and continuing, and exaggerated resulting functional action, the events of its formation as they occur, up to a subsequent and necessarily equalizing growth of the process (as regards systemic depletion and relief of morbid pressure) and its complete development. It also sets forth the causes for the self-limitation of the process, which are shown to be purely physical or mechanical in their action; and further shows that this generally recognized character of the disease, self-limitation, cyclical, is the logical and unavoidable consequence, through physiological action, of the events of the process; or, in short, of its own formation. Furthermore, the conditions during complete consolidation have been detailed; and the course of restoration of the involved lung to normal conditions and functional activity, through degeneration, liquefactive softening and absorption of the exudate, with consequent pari passu relief of the pathologically created, extra-vascular lateral pressure upon the capillaries, and resumption of circulation through these vessels, is also given.

I claim that such exposition is based upon adequate and logically scientific reasons, and that it correctly represents the process of the local affection of this disease.

First.—That the local process is the cause of the constitutional symptoms, and, therefore, essentially constitutes the pneumatic disease, we have already partly seen in our study of its special or functional pathology, as given; where we found, (1) that the deranged circulatory phenomena—the obstruction of the blood in the lungs, the small arterial pulse, venous fulness and distension, approximate and in some cases dangerous increase of pressure in the afferent vessels before the obstruction, the overworked and possibly the overpowered right heart, and dierotism, (2) the respiratory difficulties—blocking of a portion of the pulmonary structure with the consolidate, with congestion and more or less edema of the remainder, and a consequent degree of asphyxia, (3) the nutritive derangements—anorexia and aepsia, (4) the ex-
cretory—scanty urine and constipation, (5) the nervous—anxieties, mental depression, delirium, and generally depressed nervous action, and (6) the sphenic derangements, or an early, exaggerated, and exhausting functional action, and a later corresponding and marked asthma—were all to be accounted for by direct reference to the local obstructive cause. Again, in my scheme as set forth, and especially in its exposition, I have shown how the well-recognized constitutional, cyclical character of the disease and its self, limitation are to be accounted for; the former, by the varying conditions of the local process of accretion and decre- tion, or of development or formation and decrease or re- moval, and its consequently varying inhibitory effects upon functional action and sphenic reactions; and the latter (in a constitutional sense), by a resumption of circulation through the resolving, softening lung (the stoppage of which is the secondary consequence of such limiting action), to which resumption, I clearly show in my study of that event (in symptoms and course), we must attribute the phenomena of crisis—namely, the remarkable cessation of symptoms which occurs with that event, not otherwise explained. That the singular, I may say unique, defervescence which occurs with crisis, also cessation of morbidly increased respira- tory movements, relief of the right heart, improvement of pulse in frequency and fullness, functional resumptions—as shown in an increase of urine, in recurrence of appetite and of bowel action, and in the mental relief which the patient subjectively experiences, are due to this cause (re- sumption of circulation), we may infer from the softening exudate as determined by physical signs, and also by gen- eral physical observations, notably with regard to arterial and venous conditions, and especially as to the peripheral capillary circulation, and an equalization (normal) of bodily warmth. Furthermore, in my discussion of these symp- toms, I shall show that the febrile manifestation, "febris pneumonica," and dyspnea, which cannot be accounted for by the extent of the local lesion simply, but results in part, also, from general collateral congestion and edema, and is especially due to morbid pressure, and the hectic cheek, not before traced to a cause, are to be explained by reference, directly or indirectly, to the local obstructive process.

Thus we may conclude that the constitutional phe- nomena, however characteristic, synthetic, regular, and cyclical, and, therefore, seemingly essential they may appear to be, are due to and result from the local cause—which, as Jürgensen very truly says, "is the only constant element" in the disease. For the same reasons we may also conclude, in accordance with this hypothesis, that the local anatomical process of acute lobar pneumonia is its essential feature, and the cause of its entire pathological phenomena.

SECOND.—That the primary initial lesion of this process is a pulmonary capillary insufficiency, as claimed, we may conclude, (a) because, as we have seen, the process which follows is not inflammatory, and hence must be dynamic; (b) because it is possible upon this hypothesis, through im- mediate collateral action, in the manner pointed out, to explain the concrete extension of the process and the events which follow; (c) because functional insufficiency is not an unusual event or condition, and with reason may occur in these vessels. It forms the basis of varicosities and of aneu- rysms, and is illustrated in cardiac insufficiency, also in atony of the bladder. Wherever a vessel or an organ is subjected to a pressure it can not tonically withstand, either because it is wanting inherently or in collateral support, it may be- come insufficient; this fact is further illustrated in varicoceles, in hemorrhoids, and in the fine aneurysmal distensions or saculations met with in certain pathological conditions of the cerebral vessels.

The histological character of the exudate, which follows as a result indirectly of the primary lesion, and the course of the exudate (physiological and pathological), indicating without doubt, its origin in the blood, justify the deduction that its extra-vascular position could only have been reached as the result of pressure—dynamic action; and it is clear that, if pressure caused its extra-vascular position, the exu- date or extravasate occurred through the weakest segment of the involved vascular continuity, hence through the cap- illary walls. Furthermore, as we have seen, the anatomico- physiological conditions which relate to the pulmonary capillaries are most favorable for the development of their insufficiency (first, functional; second, organic or structural); to wit, of themselves they are extremely delicate; they are also, for functional reasons, singularly unsupported, being bounded by air-spaces only; and, on the other hand, the energy which may be developed against them by the circu- latory organs and forces, acting through the hydrostatic blood, is most ample to cause this condition, especially when a predisposing state of debility exists in them.

THIRD.—That the remaining claim for this hypothesis is valid; that acute lobar pneumonia is a dynamic malady (the term dynamic being understood to include a predisposing adynamia of the pulmonary capillary tissues—their struct- ural asthenia, on the one hand, and the action of an ade- quate force, dynamia, generated in the functional circulatory apparatus, and applied, possibly spasmodically, through the incompressible mobile blood, on the other) is apparent from the facts of its etiology in general. As we shall find from a full and careful study of that branch of our subject, there are, besides the more generally acting causes, four quite special classes of conditions which are fruitful, geneti- cally considered, of the disease—all of which affect dynamic conditions, either by contributing to depress the vital re- sistant tone (local, or general including the local), adynamia, or by favoring, through predisposed spasmodic action, the development of a suddenly acting afferent pulmonary blood-pressure—dynamic. These more frequent conditions are: (1) exposure; (2) degenerate fatty habits, involving structural asthenia; (2) neuroasthenic states, including those con- ditions of nervous depression resulting from confinement, especially where such is punitive, also where depression results from nervous shock, and particularly from the shock of extensive traumatism, especially of major surgical opera- tions (prior to the use of anesthetics); (4) age. It may be remarked here, in support of a still further claim made, that the first three of these classes refer, as will be readily apparent, to avoidable conditions, and, therefore, they are to a large degree preventable. And, while age itself can not
be classed as preventable, yet even in this the exciting and immediately casual conditions are partly so.

In regard to the question of exposure, or the moot question of “the taking of cold,” as constituting an active cause for pneumonia, while opinions are strongly opposed on this point, it seems to me they may be reconciled with little difficulty. As we shall see when we come to the study of causes, attacks of this malady are frequent results of taking cold, although those who lead exposed lives are not especially liable to it. A solution of the seeming discrepancy of these observations is to be found by determining what constitutes exposure. The term exposure has unquestionably a relative significance. It relates especially to the results produced; and these, again, depend upon conditions and powers of resistance of the persons subjected. This will be apparent from the following:

Persons constantly exposed to the vicissitudes of climate, like sailors at sea in every quarter of the globe, and soldiers in active service, are not subject to pneumonia; while, on the other hand, soldiers in garrison, where there is more seeming protection, are more liable to be attacked than those in the field. Officers in garrison, however, are less liable than the rank and file (von Ziemssen’s “Cyclopedia,” vol. v, pp. 19 and 26). An explanation of these facts is readily found in the sthenic dynamic conditions engendered and the relative exposure (according to the above interpretation) undergone. Sailors at sea and soldiers in active service become acclimated, dynamic to resist, through the daily services they perform; and climatic changes which would constitute exposure to others less injured are not experienced as such, or as severe, by them. Furthermore, the activity of both kinds of service alluded to conduces to a resistant tone of the tissues, and does not favor a replete blood state—two results which tend to preserve a normal relation, static and dynamic, between the vessels on the one hand and blood-pressure on the other, and, therefore, are eminently preventive of the disease we are studying.

In garrison life, conditions are very different from those in the field, and, as might be supposed, generate very different physical conditions, the result being both dynamically and physiologically predisposing. The rank and file in garrison are not daily exposed, or sufficiently so to acquire the vigil and conditions of physical resistance adequate to constitute a safe dynamic acclimatization, and their idle habits—inactive lives with an ample dietary—conduces to that structural asthenia, replete blood state, and functional and nervous irritability, which render soldiers so environed especially liable to suffer from whatever exposure they may chance to undergo in the occasional, but imperative, sentry and other duties. Hence, while the necessities of an active life cultivate an immunity from pneumatic attacks by exposure, the conditions of an idle, irregular, and indulgent existence conduces to render exposure a more frequent cause of its occurrence; from which it may be seen that dynamic conditions in these cases govern its genesis. That the officers in garrison suffer less than the rank and file from pneumonia is to be explained upon a like interpretation with the above. Officers in garrison are comparatively more engaged, mentally and physically, than common soldiers, and their physical tone is also improved on account of their superior social advantages, both of which favor a better hygienic state and more normal dynamo-physiological conditions; again, they are less liable to the occasional enforced duty—sentry or picket—which comprises the chances of exposure; hence their immunity.

As a deduction from the above, we may say: While exposure is a prolific cause of pneumatic attacks—as it undoubtedly is in a large aetiological survey—it is so only in an immediate or exciting sense; and its action as such depends upon predisposing conditions. The results of an exposure vary in every case with the capacity of the individual for resistance—with his relatively normal and dynamic states. It is upon the ground of this deduction—incapacity for resistance—that we can explain the occurrence of attacks of pneumonia from even moderate exposure in persons whose tone, structural and nervous, is poor, but whose blood state, as to amount, is normal or full; also upon the same ground of inability to resist its effects—internally determining, driving the blood upon the pulmonary capillaries—are we to account for a quickly developing pneumonia from “taking cold.” A person—in whom there is a predisposing physical condition, full blood state with a non-resistant cutaneous condition, and poor structural tone,—structural adynamia—takes more than his usual exercise and gets very warm, he sits in a draft and takes cold, and, as a consequence, has pneumonia.

While in the cases given an adynamic state—a condition of delicacy, conjoined with an exaggerated reflex nervous, muscular, and circulatory condition—exists, in another class of cases, where pneumonia develops in the young and full-blooded (as it may from exposure) reflex and sthenic dynamic conditions more likely preponderate; although in these, also, there may be at the moment a lack of normal structural integrity as a predisposing adynamic cause. In another class of cases again structural conditions may be normal; but the reflex conditions are highly irritant, and the blood volume is great; here exposure results in a pneumonic attack through sthenic causes, the action of an adequate blood pressure merely, unaidedly adynamic predisposing conditions beyond nervous irritability. Lastly, that dynamic conditions prevail through exposure is evident, on the other hand, from the fact that in the hardy and acclimated no amount of exposure will set up the disease.

b. Degenerate fatty habits or tissue states, including structural asthenia, comprise the second class which illustrates the dynamic character of this pathogenesis. With the fatty degenerate structural state there is usually a co-existing condition of hemic repletion. These predisposing conditions may or may not be conjoined with a still further predisposing cause—nervo-cutaneous irritability. This class of cases is met with in the good livers and physically indolent (though the latter is not strictly necessary) in our midst.

Though presenting, in one sense, fine physical appearances, these subjects possess no tone, no capacity for resistance or endurance; they are adynamic, and, when from any cause there is created a determination of blood inward, the
impingement of the volume and force so set in motion upon
the adynamic capillaries may result in an attack.

c. Neuasthenie states, as set forth, resulting from over-
work, great mental strain with anxiety, mental depression,
faulty and imperfect nutrition, from confinement, especially
with long hours of mental labor, or where such is puni-
tive and, therefore, greatly depressing, and from shock,
particularly as noted of extensive traumatism, further illus-
trate the influence of dynamic conditions for its develop-
ment.

d. It is hardly necessary to more than refer to the only
conclusion that one can arrive at, that the asthenia of the
aged, the depreciated structural tone of their circulatory ap-
paratus—in fact, adynamia—is the cause of the frequent
occurrence of pneumonia in these subjects.

Lastly, that this disease is a dynamic malady is quite
conclusively shown by one well-recognized characteristic of
its genesis. It has long been observed that the favorite site
of a pneumatic process in the class of the disease we are
considering, acute lobar, is in the lower lobes of the lungs,
but that it is more frequently than elsewhere located in the
lower lobe of the right lung. This local preference for the
action, except upon the hypothetical ground of some un-
known deprecatory, selective action not proved, has not here-
tofofore been explained. As has been shown, the local mor-
bid expression of this disease can not be deprecatory; its
continuous local, not diffuse, multiple, expression or mani-
festation, rendered further conclusive by anatomical and physi-
ological deductions, disproves such an action; and hence a
selection of the site resulting from some character of the
poison (?) to be eliminated is naturally untenable. The anato-
metrical identity of the lung structure throughout would
also seem, of itself, to negative such action.

Although certain morbid processes of a decidedly chronic
inflammatory character manifest well-known local preferences of
site, notably chronic tuberculosiis for the upper lobes of the
lungs, yet, as I have shown this process to be non-inflamma-
tory, its most frequent localization can not be accounted for
thus on the ground of possible precedence for such action.
Furthermore, as this process is decidedly acute, not chronic,
and as it does not invariably attack the lower lobes, but
may occur in any region of the pulmonary organs, some
other influence than any yet suggested must determine the
preference of the action noticed; and this I shall show,
other things being equal, is dynamic. It is reasonable to
conclude that in and throughout the lungs, as in other parts
of the body, there may develop a local asthenia, which,
under an adequate blood-pressure, will determine the site
of the development of a pneumatic process for that locality.
But where the tonic resistance is equal throughout the pul-
monary capillaries (and it may be everywhere below nor-
mal), it is evident that an abnormally developed pressure,
spasmodic in character, or tonically sustained, will be felt
most, or will act with most effect, upon that area of the
capillary circulation or vessels which is located in that
line from the source of the energy creating the pressure,
which affords the least resistance to the circulating blood,
the medium acted upon. Such line from the right heart,
and in concordance with the energy of the great moving
blood stream, as the blood enters the pulmonary artery and
divides into its different branches, will strike the capillaries
of the right lower lobe. This is so, for anatomico-physical
reasons. The least resistance is naturally met with in the
course of the larger terminal currents, and in that portion
of the lungs to which the larger of the related branches of
the pulmonary artery tend. According to Gray ("Anato-
my and Descriptive Surgery"), the pulmonary artery divides
into two main branches, the right and left pulmonarys. The
right, larger and larger than the left, divides again into two
branches, of which the larger is distributed to the right lower
lobe, the smaller being distributed to the two upper right
lobes. The right pulmonary, therefore, is not only larger
than the left, but its lower division is larger than its upper,
which again divides (unequally) to supply the two upper
right lobes. The line of least resistance, so far as friction
from the vascular walls and divisions of the current by vas-
cular branching is concerned, then, would tend to the lobe
most frequently affected—the right lower. But the larger
vessels also, in addition, circulate the greater and, therefore,
heavier volumes of blood; and, as momentum transmits en-
ergy in proportion to the weight of the median in motion,
and as a heavier volume of circulating blood would impinge
against the vascular walls with greater pressure than a small-
er, this affords an additional reason why, tonic resistance
being equal throughout the pulmonary capillaries, the vessels
of the right lower lobe should yield first, and become first
insufficient under a given adequate pressure. For the same
reasons—dynamic, on account of the greater liability of
both lower lobes as compared with the upper to be affected
by circulatory pressure—both, as derived from a greater
momentum and additional weight of the blood—we see why
the lower lobes are more frequently the seat of pneumatic
processes than the upper.

Thus are the several claims for the essentially dynamic
character of this malady verified, and the writer's reasons
for the truth of the hypothesis, as set forth, given.

That this hypothesis is essentially true will be clearly
shown in a subsequent study of the morbif anatomy; and
is evident also (1), because it is in itself synthetically,
rationally, and logically complete; (2) because upon it, and
it only (so far as known), can be explained the otherwise
obscure pathogenesis of the affection; (3), because it affords
a rational explanation for its varied pathological phenomena,
both local and constitutional, and includes, also, as we shall
see, ample reasons for the imminent dangers and even the
occurrence of sudden death it involves; (4) and lastly,
because, as will be shown, it not only affords an ample basis
upon which may be constructed an inductively rational
therapeutics, but upon it also, as will be pointed out, we
are able to explain the beneficial action, extent, and limita-
tion of those remedies and plans of treatment which, at vari-
ous times and in various hands, have proved useful.

Having determined from the foregoing that in acute
lobar pneumonia we have to deal only with what is essen-
tially a dynamic malady, including a local adynamia (struc-
tural) and general dynamia (physiological, constitutional),
its further comprehension becomes very simple, and its
therapeutic management comparatively easy.
THE LOSS OF TENDON REFLEX, 
NOT SIMPLY ITS ABSENCE, 
THE SIGNIFICANT SIGN IN LOCOMOTOR ATAXIA.

By C. H. Hughes, M. D., St. Louis, 
LECTURED ON PSYCHIATRY AND NEUROLOGY IN THE ST. LOUIS MEDICAL COLLEGE.

Before the Missouri State Medical Association, June, 1869, and published in the "Alienist and Neurologist" for January, 1880, the writer presented an inquiry into the clinical significance of absent patellar tendon reflex, maintaining, among other things in regard to it, that its mere absence was not always of certain diagnostic significance with reference to the existence of posterior sclerosis, and that sometimes its mere absence was apparently of no definite pathological import.

That the sign is not infallible (so infallible as stated by Westphal that its discovery indicates approaching ataxia even before other corroborative symptoms show themselves) may be demonstrated by diligent examination of the tendon reflex responses among a large number of healthy men, in a small per centum of whom it will be found that tendon reflex, like ticklishness, is sometimes nil even without apparent pathological facts to warrant. Tendon reflex, too, like sensitiveness to titillation, depends upon states of the cord and nervous system not always organic, and not, in all persons, pathological. It is not our purpose, however, to go over again what we have already once said with reference to this sign, but simply to emphasize the fact that it is not the mere absence of the patellar tendon reflex that is of significance in posterior spinal sclerosis, but its disappearance in one who has before possessed it, and that the sign is one of comparative rather than of absolute diagnostic value, and not at all the definite and specially significant one that it has been claimed to be, though it is singularly significant that it is seldom absent in well-established and undoubted locomotor ataxia, except where certain portions of the cord have escaped morbid implication. Since the writing of our paper in 1869, repeated observations have only tended to confirm the views then expressed respecting the value of this sign, and we hope that the subject will not be permitted to rest precisely where Westphal and Erb have placed it, but that observations will be made more extensively upon healthy persons respecting this sign, and upon its behavior in other morbid conditions than sclerosis posterior—non-organic affections of the brain and cord. It will then be found that, as Seguin, McLane Hamilton, L. C. Gray, Jewell, Banister, and myself have observed, the sign is at least not absolute.

This note recalling attention to this subject has been inspired by two recent cases—one observed during the past week in the person of a patient (sent me by a physician of Texas) suffering from surface hyperesthesia of the cutaneous distributions of the crural, especially those distributed to and about the knee joint, which followed a prolonged and protruding left sciatico-eruvalgia; the other was last month shown me by Dr. Hammond at the neurological clinic of the New York Post-Graduate Medical School in the person of a physician, free, so far as either of us could discern, from any nervous disease. And in these cases the most thorough attempt failed to elicit the patellar tendon reflex response.

Another case has to-day been dismissed from under my care in which there is no knee phenomenon on the left, and a scarcely perceptible clonus in the right leg. The patient, a miller, aged fifty-six, presented himself with cerebral hypeheuma, impotence, and absent cremasteric reflex, a sign which, by the way, I have found not infrequently in ataxies, and which, when it fails to be elicited by electrical excitation, appears of real diagnostic value in seeking to decide upon the existence of sexual impotence in the male.

If this note shall inspire a rational skepticism as to the absolute infallibility of absent patellar tendon reflex, without implanting undue doubt as to its real importance when lost by one who has once possessed it, and who is not under the influence of cerebral states other than those induced by sclerosis which impair or take it away, its true design will be accomplished. To this end inquiries, which we have not now time to make or tabulate, should be further made into the reflex responses of the healthy, the comparatively healthy, and among those who have cerebral trouble with and without sclerosis. An unbiased and extended inquiry will reveal the fact that absent patellar tendon reflex is not the sign, although when lost it is undoubtedly a significant symptom, and points more frequently than elsewhere to posterior spinal sclerosis, as originally contended for by Westphal and Erb, i.e., when other signs of ataxia coexist.

The absence of the cremasteric reflex—it is more difficult to ascertain if it has been lost—presents a symptom confirmatory of diagnosis which justifies testing for it in all cases of suspected ataxia, but we have not time now to digress to its discussion.

1710 Chouteau Avenue, St. Louis.

A SUCCESSFUL CASE OF PLACENTA LATERALIS.

By Stanley P. Warren, M. D., Portland, Me.

There appears to be a striking variance in the treatme-theoretical and practical—of placenta praevia between the obstetricians of the modern school of practice and of the past. A recent treatise on midwifery says "most authorities advise the expectant treatment of placenta praevia, partly for the sake of the child's interests and partly on account of the difficulties in inducing labor, due to rigidity of the os." In Playfair's formulas for the treatment of this grave accident of parturition we find: "II. In hemorrhage occurring after the seventh month of gestation no attempt should be made to prolong the pregnancy," p. 405. Says Lusk: "On theoretical grounds, the induction of premature labor is to be regarded as obligatory, and as soon as the diagnosis of placenta praevia is established, or at least with the occurrence of the first hemorrhage," p. 559. He quotes Barnes as saying: "If pregnancy have advanced beyond the seventh month, it will, as a general rule, I think, be wise to proceed to delivery, for the next hemorrhage may be fatal." Accepting, as we do, the high authority of these practitioners, yet "circumstances
alter cases." Gestation may sometimes be permitted to terminate at the natural period, when compliance with the hard and fast rule of delivery at the pleasure of the operator would make good Lask's remark, that "the accouchement forcé, performed with rigid cervical canal, is perhaps, next to doing nothing, the most responsible cause of the mournful results on record."

As a first step in the treatment of placenta previa, the abnormal position should be established exactly, or to a reasonable certainty. This will, almost as a sequence, predicate the amount of hemorrhage and the dilatability of the cervix. Now, if the implantation is central, there would seem to be no question as to the propriety, nay, urgency, of active interference. All risks of shock, laceration, etc., from forcible manipulation are practically less to be feared than the impending flooding. But when the case is one of "placenta marginalis," there are sometimes factors that will tip the scale in favor of procrastination—such, I suggest, as are attended by small and infrequent hemor-

rhages, that begin in the last month, with healthy constitu-

tion, and nearness of residence to the physician. When such conditions obtain, and especially when with these there is a vertex presentation, delay may be safer to child and parent than forcible dilatation and version.

Among the surprising things of medical practice is the frequency with which placenta previa comes to the obstetricians. A friend in active professional life thirty years has never met a case; another found it in his first patient. After ten years of obstetrics, it has lately occurred to me. Nothing is so futile as to reason from one case; nevertheless, when added to others, their sum can be utilized in the induction of warrantable inferences.

The patient is of American birth, in the middle class of life, thirty years old, perfectly healthy, and the mother of six children. During the present gestation she has suffered in no way from her usual mode of life—the care of her home and children—except in using the sewing-machine more than usual. She expected her delivery October 11th, though by professional com-
p: count back three months and add seven days—it should occur October 17th. On the afternoon of September 27th, just four weeks from the actual delivery, vaginal hemor-

rhage began, without pain or evident cause, saturating three or four napkins. I found her soon afterward still flowing, though the amount was steadily lessening. Careful examination showed the following condition: Per vagina, cervix an inch long, ad-

mitting the index-finger, the anterior cervical segment hard and resistant, the rest of the neck faced, cephalic presentation, position not defined. Externally, by palpation, the uterus reached the sternum, the contour of the fetus was readily out-

lined, there was little amniotic fluid, the head was in the left groin. By auscultation, the fetal heart was heard at middle left side of the uterus. 144. The so-called placental souffle was heard most distinctly on the right, low down, about the level of the pelvic brim, and gradually disappeared upward. Diagnosis, placenta partialis, fetus in left occipito-anterior position. She was directed to stay in bed and to take an enema of 40 cc. of laudanum once in three hours. If hemorrhage occurred, to summon me at once. Forty-eight hours afterward there was a second hemorrhage, small, and with no uterine contractions perceptible. I was not notified of this one until a third bleed-
ing occurred, on the evening of the next day. I ascertained that the hemorrhage was about as much as at the first, the cervix unchanged, no true labor-pains, and the patient wished to "get up and go to work." As she was still flowing a little, I tamponed the vagina firmly through Sims's speculum. Having another con-

firmation that night, I was detained, so that I did not visit her until the evening of the next day. After the tampon had been tolerated nearly twenty hours, she herself removed it, and there had been no recurrence of the flow. She was absolutely free from pain, and the uterus was unchanged in condition, the pulse was full at 78, no rise of temperature, and no symptoms of exhaus-
tion. After consultation, it was decided, in view of the existing state of affairs—little and infrequent hemorrhage, the certainty of shock in forcibly dilating the cervix, soft on one side, hard on the other, and the generally excellent condition—it was the part of wisdom to preserve a "masterly inactivity." This was on October 2d. She resumed her daily routine work, and did not flow any until October 21st, then only staining two napkins. October 25th, while at supper, she felt a sudden gush of blood, that soaked through her clothing, fainted from nervous shock, and went at once to bed, where I found her in an hour's time. There had been hemorrhage enough to saturate the bedding about as much as we usually find it at the end of a natural delivery, and there was then a trickle of bright blood. The neck was effaced, the os open about two inches, dilating pains severe and nearly constant, the head presenting and finally applied to the lower uterine segment, membranes unruptured, the edge of the placenta could be indistinctly felt within the orifice, and thin clots were between the uterus and membranes. As dilatation progressed, the bleeding entirely stopped. At ten o'clock, four hours from the beginning of labor, the os having nearly fully opened, I ruptured the membranes. No water escaped. In six or seven pains the babe was expelled, having the cord wrapped once about its neck, somewhat cyanosed and feeble, but there were soon evidences of vigorous life. The offending placenta was expressed manually, and compression kept upon the uterus by my hands for an hour. Contraction was most thorough, indeed almost teneo and character, and there was very little flowing after the placenta was removed. For several hours there were moderate after-pains, which I do not think were due to internal coagula, for none were afterward expelled. Lactation was perfectly established at the third day, tempera-
ture, pulse, and lochia were normal the fourth morning, and there has been a perfect convalescence. She says that she had an easier labor than any preceding.

The placenta was of usual size, the cord was implanted in its upper third, while its lower third presented a unique appear-

ance. It was smaller than the part above, the constibution be-
ginning abruptly, firm and bloodless, looking very much like an old, well-worn sponge, and was evidently the result of long-con-
tinued, peculiar compression. The attendant noticed at once its unusual appearance, and accepted readily the explanation given.

One or two points in the history of this fortunate case are, to me, worthy of especial notice. 1. The small amount of flooding proportionate to the large amount of detach-

ment.Fully one third of the placenta was altered in size and macroscopic appearance, and the atrophy seemed to have existed for some time, judging from the bloodless, non-su-
culent tissue. There must have been a sudden rupture of large sinuses just before actual labor, for the hemorrhage then was more than the entire loss in the preceding ones.

2. The unusual vigor and efficiency of the dilating pains. Lask says: "During the first stage the pains are apt to be feeble and dilatation tardy," p. 556. Playfair: "Pro-

vided the pains are sufficiently energetic, Nature may be capable of stopping the flooding without artificial aid. It
is but rarely that she can be trusted for the purpose," p. 399. In the case reported, the pains of the first stage were nearly without intermission; and the os was fully dilated in three hours. By their influence the hemorrhage was speedily arrested which was so profuse at the beginning of labor, and this well demonstrated the opinion that good uterine contraction is a sufficient hemostatic.

3. Again, the worth of manual compression of the emptied uterus is shown by the slight post-partum bleeding. This re-enforcement of natural uterine action was begun as soon as the child emerged from the vulva, continued for an hour, and, by its aid, the womb took on an almost stony hardness. No ergot was given at any time in the history of the case. The behavior of the uterus, in this and preceding patients, when no ergot was used, contrasted with those to whom it has been administered, convinces me that manual compression, thoroughly carried out, is as efficient in preventing post-partum hemorrhage as ergot, and without its dangers.

4. A fourth point is the failure of the tampon to induce labor. The vagina was thoroughly packed, through a Sinus's speculum, with cotton pledgets, which, though effectual as a hemostatic, entirely failed to bring on the labor. It might have resulted differently if a sponge tent had been inserted into the cervix; and, indeed, a similar failure has often occurred to me when the vaginal tampon alone has been applied in abortions. It goes to show that merely a vaginal tamponade can not be depended upon to arouse uterine contractions.

5. Regarding the so-called "placental souffle," Playfair remarks: "The non-placental origin of the sound is sufficiently demonstrated by the fact that it may be heard for a considerable time after the expulsion of the placenta," p. 148. "Its position (the uterine souffle) can not be taken as a safe guide in determining the situation of that viscus" (placenta), p. 149. "The accuracy of our diagnosis may be confirmed in doubtful cases by finding that the placental bruit is heard over the lower part of the uterine tumor," p. 396. However we may reconcile these seemingly contradictory statements, and whether or not the uterine souffle does indicate, physiologically, the site of the placenta, still, as a matter of fact, in this patient the sound was heard most distinctly at the point where the afterbirth was situated, that attachment being established to be lateral by the examining finger and by its own configuration.

RUSSIAN VAPOR-BATHS
A CURE FOR BLOOD-POISONING.

By TRUMAN S. SUMNER, M. D.

On November 11, 1879, Professor Howe transfused eight or nine ounces of blood in the case of Mrs. B., exhausted from profuse bleeding after miscarriage at the third month. (See the "New York Medical Journal," vol. xxxii, p. 152.)

It fell to my lot to nurse the lady exclusively for twelve or fifteen days. By frequent enemata of fresh bullock's blood, and the juice of raw beefsteak by the mouth, her vitality was so increased by the next day that a second transfusion was unnecessary. Several abscesses formed where the hypodermics of ammonia, brandy, and morphine had been given, due to such a low condition. I was poisoned in dressing these, or in using the vaginal injections, through a wound on the thumb; I lost the nail, had a phlegmonous abscess on the forehead, several styes, and a dry, harsh skin. The prognosis seemed very unfavorable. I was advised to go to the Hot Springs of Arkansas, but, having been an occasional visitor at the Lafayette Place Russian Baths, I knew that the relief needed could be found in their soothing vapor and sweat-producing, dry hot-air rooms. After a few weeks daily bathing the barber noticed a marked change in my hair: that it was softer and oily, and our attendant remarked the healthy action of the skin, which had lost its dry, dead condition—in other words, every pore was doing its duty, perspiring readily at 110° and 140° F.

As is well known, healthy perspiration is never weakening; the loss of tissue is quickly made up by abundance of nourishing food. Thus the fluids of the body that have been drained off are supplied, its solids are maintained, and the standard of the physical strength is not only kept up, but increased by combined healthy exercise, pure air, and good nourishment. The appetite being rendered vigorous, the food taken is rapidly assimilated, and the body is really and ultimately strengthened. In fact, this system of bathing is the blissful cause of exciting a harmonious working of all the functions of the external and internal economy of the body.

Encouraged by a few weeks' daily bathing, I accepted a position in the electric department, and continued this systematic sweating daily for a year, the entire process lasting about an hour each time.

The first step was an exposure of about fifteen minutes to a temperature of 110°, reclining on marble slabs or walking around the spacious chamber at pleasure, using a sponge dipped in cold water on the head, at first, when it was a difficult matter with my dry skin to perspire freely, or tepid showers to relieve this dryness and hasten the sweating. Then a scrubbing with soap and brush, followed by a tepid shower, removed all the debris and admitted of a pleasant stay of ten minutes in the soothing vapor-room at 110°; then a dip into the Cotron or the artesian plunge at 65° would exhilarate the system, and permit me to lounge for another ten or fifteen minutes in the dry-air chamber at 140°. Occasional sprays from the needle-bath of cold water would freshen up the system and bring about a good reaction. Some bathers prefer a cold shower or spray to the plunge; the result is the same, only a few more showers are needed in cooling off. When free perspiration has been attained, and a good reaction can be felt tingling the skin all over with a glow following a cold shower or plunge, then a dry rub or shampoo, at the hands of an attendant for a few minutes in a room at 75° or 80°, places the skin in a good condition to receive oxygen freely while reclining on a couch under a sheet, or leisurely dressing.

Twelve months of this treatment, with cold-liver oil and good diet, brought me up to my normal standard. The past two years I have taken three or four baths a week with great comfort, and shall continue one a week for the preservation.
of my health. With me this system of bathing had the diversity of travel, as I was thrown with an intelligent, good-natured class of people, some in search of health, others of pleasure. All thoughts of the sick-room vanished amid this atmosphere of cheerfulness.

If the patient will use this bath with diligence and care, he will prolong his life, fortify his body, diminish his ailments, augment his enjoyments, and improve his temper; then, having found something beneficial to himself, he may be prompted to do something to secure the like for his fellow-creatures. Hence this article.

Clinical Reports.

VIENNA POLIKLINIK.

CLINICAL REMARKS ON DISEASES OF CHILDREN,

By Professor Alois Monti.

October 12, 1883.

Congenital Cyanosis.—Bronchial Catarrh.—Aphthous Stomatitis.

Case I.—You have here, gentlemen, a child which, from the mother’s account, has been cyanotic from its birth. He is four years old, yet he is scarcely as large as a child of two. On careful examination, you see the marked blueness of the face, particularly of the cheeks. Even the tongue and mucous membrane of the nose and mouth are blue; hence this is a general cyanosis, not confined to the skin. The hands are congested, and there is a peculiar swelling of the tips of the fingers and toes.

When the child cries there is a general venous congestion. This is a very striking and interesting case, but the interest does not lie in the cyanosis alone. The child is unable to walk or talk; his head is abnormally small—in fact, microceplale; the fontanelles are not yet closed. The penis is only as large as that of a new-born infant. The testicles are present, but are remarkably small. In short, the child is an idiot. This is undoubtedly a disease of the circulatory system, and probably some defect of the heart. It must be congenital, for not otherwise could such extreme cyanosis result. By careful percussion, I find that the heart is not enlarged. This is very important, for in acquired heart disease the heart would be enlarged, while in this case, on the contrary, it actually seems to be rather smaller than normal. The apex-beat is not definitely located. On auscultation, you will hear a loud, blowing systolic murmur at the base. Hence we must infer, first, that there is no enlargement; secondly, that the apex-beat is diffused; thirdly, that the ventricular tone is normal, and, lastly, that there is a systolic murmur at the base. Both pulmonic sounds are accentuated, and there is a blowing murmur with the first aortic sound. Now, I would ask, What have we here? Is this a case of open foramen ovale, of congenital pulmonic, or aortic defect; is the septum wanting, or does the ductus Botalli remain patent? We can not definitely say; all that we can tell is that there is a murmur at the base, which may be due to an open foramen ovale, or to a defective septum. The former is more probable. For us, as practicing physicians, it is enough to say that the child has some congenital defect about the heart. The anomalous appearance of the head and sexual organs is interesting, but this has no connection necessarily with the other conditions. The prognosis in these cases of cyanosis is most unfavorable. Such children usually suffer from bronchial catarrh, and are liable to die suddenly from acute congestion within the first four or five years of life. As to the prognosis in the present case I need say nothing; it is very bad. We can do but little in the way of treatment except to give tonics, regulate the diet, and administer stimulants as required.

Case II.—This child has a cough, and, as the mother says, seems to suffer from pain in the abdomen. It is not unusual in pneumonia, either of the upper or lower lobe, for the pain to be referred to the belly. In pleurisy in children the hydrochon- drium is generally the seat of pain. By further questioning I find that two days ago the child suffered from pain in the breast, and dyspnoea. On examination, you see that the face is pale, the general surface temperature somewhat elevated. The respirations are not much accelerated, and there is a slight cough. Auscultation of the right back shows roughened respiration, with moist rales; the same is heard on the left side. You see that I listen to the chest first because the child begins to cry if I peruse. I also employ immediate auscultation, as chil- dren are less terrified than if they see a stethoscope. Many differ- ent instruments have been devised. We use here a stetho- scope invented by Rousseau, which has a small rubber bulb attached to the mouth of the instrument, so that the air can be exhausted. Two long, flexible rubber tubes connect it with the ears. The advantage of the instrument is that it adheres to the skin and is not detached by the child’s uneasy movements. As I said before, we find here roughened respiration and rales, but without dullness on percussion. Hence this is a catarrh of the bronchi. It is important to decide whether the large or small bronchi are affected; if the small, the respirations will be very frequent. This is not the case here. The respirations will be labored in capillary bronchitis, and there will be movement of the ala nasi with action of the muscles of the neck. This symptom is also absent in the present case. The treatment is simple. The child should be kept in bed and have its chest en- veloped in wet compresses. There is no specific treatment. You can give some simple expectorant, and, if there is elevation of temperature, a teaspoonful of salicylate of soda (a five-per- cent. solution) may be given every three hours as an antipyre- tic.

Case III.—This is a case of aphthous stomatitis. It is a dis- case most often seen in summer, and seems to be due to some fermentative process. It is often preceded by a considerable elevation of temperature (39°-40° C. [=102°2'-104° F.], lead- ing to the inference that pneumonia is threatened. Then comes salivation, attended with heat, redness, and swelling of the buccal mucous membrane. The child loses its appetite simply because the presence of food in the mouth causes pain. After twenty-four hours the fever declines, and, simultaneously, small vesicles appear on the mucous membrane of the lips, tongue, and gums. On the first day five or six vesicles are seen, on the second as many more, and so on. By confluence of these large pustules are eventually formed. In this case you can see all of these different stages. Salivation is present. Here are vesicles on the lip and tongue, and on the roof of the mouth is a large purplish spot. This is not diphtheria, but confluent aphthous stomatitis. The child infects itself through its saliva, and, in a family where several children use the same glass or spoon, the disease spreads. Hence aphthous stomatitis is infectious. The prognosis is favorable, though, if the affection lasts for twelve or fourteen days, the child may become emaciated through loss of sleep and appetite. In some cases the larynx may be af- fected, leading to edema of the glottis, and a consequent diagno- sis of diphtheria.
Book Notices.

This treatise is already well and favorably known to the profession, and it seems only necessary to indicate the alterations made in the present publication. For these the American editor is altogether responsible, as there has been no more recent English edition which he could draw upon. The most striking difference that we have noticed in a cursory comparison of the two editions is the change made in the arrangement of the topics. Dr. Bull has evidently endeavored to bring the subjects into a more logical and more natural order than that in which they were considered by Mr. Wells, and his alterations in this direction have, we think, been judicious. Thus, Diseases of the Lacrymal Gland are now placed in their appropriate position in the beginning of the book, while Diseases of the Sclerotic have been placed with those of the Cornea, and Diseases of the Ciliary Body along with Affections of the Iris. Again, Diseases of the Choroid and the subject of Glaucoma precede, as they do naturally, the discussion of Cataract and other lesions of the lens. The affections of each part are now, therefore, taken up in the anatomical order, proceeding from without inward. The chapter on the Use of the Ophthalmoscope is relegated to the end of the work. It seems to us that it would have been rather more appropriately inserted in the beginning, along with a description of the other methods of examination.

With regard to the more important additions, we may point to the description of Cramail's perimeter and of the treatment of scars of the face by kneading, the account of Landolt's method of blepharoplasty, the new matter on the subjects of sympathetic ophthalmia (p. 349), upon the nature of glaucoma (p. 405), ophthalmic migraine (p. 540), and the course of the optic-nerve fibers (p. 585). The section on Ophthalmia Neonatorum has been entirely rewritten, and those upon Diphtherita and Membranous Conjunctivitis are nearly all new matter. In addition, there are many minor insertions scattered throughout the book, together with much that is new in the way of bibliography.

Altogether, we can say of this what is so commonly, though often so untruly, said of new editions, that it is both "revised and improved," for the additions enhance the value of a book already valuable to ophthalmic specialists.

This well-known work is at last reprinted in America as one of Wood's Series of Standard Medical Authors, and the first volume, in its typographical appearance, is a great improvement on former English editions, and is free from the numerous errors that disfigured them. When the second edition of Parkes's "Hygiene" was reviewed in this journal (vol. iv, p. 131), it was stated that the book was not excelled by any work on the subject then extant. It was never intended as a complete philosophy of hygiene in its broadest sense. It was originally designed as a manual for army officers, to guide them in their duties as military sanitarians; but subsequently the book was somewhat enlarged in scope, in order to adapt it to the needs of civil life, but it never fully met those needs, although, on the death of Dr. Parkes, he was succeeded by the able and versatile De Chaumont. In the revision before us, of which the present volume is the first installment, it is proposed to omit such matter as has become obsolete, and to incorporate such additional topics as the progress of science and the results of experience rendered it desirable to add." This promise has been faithfully carried out in the first volume, so far as the military hygienist is concerned, but there is still room for additional topics of interest to the civil medical officer. What the American editor is likely to add is still a matter of conjecture, although in the title-page it is stated that the Appendix will give the "American practice in matters relating to hygiene," which would seem an ample field in which to work—if there is any such thing as a practice of hygiene peculiar to America—but, whether our fellow-countryman add much or little to this book, it at this date still remains, in its peculiar field, the best work on practical hygiene extant; and when it is remembered that the world has no lack of works on hygiene, from Hippocrates down, the full measure of what we mean to say will be apparent. Other works we have in mind having each their points of excellence, but of this one we may say, take it "for all in all," we "shall not look upon its like again."

Taylor's treatise, at the hands of Dr. Stevenson, has undergone a diminution of bulk with an increase of mass. Diffuseness has given place to concentration, and the matter itself has been added to. These were needed changes. The editor observes in the preface: "In one respect I have thought it right
to tone down and curtail materially Dr. Taylor's language. I refer to that portion of the work dealing with the relations of medical witnesses to the bar. However faithfully the author's lively descriptions may have represented scenes in court between witnesses and barristers as they appeared to his mind, I felt that they were no longer applicable at the present day."

The most important accessions and alterations are found in the chapters on Poisoning, which "have been in some parts entirely rewritten." The case of Reg. vs. Lamson and the interesting toxicological considerations which arose out of it have been incorporated.

This edition only reasserts with stronger reason the allowed claims of the late Dr. Taylor's work to the first position among English books of its class. Including within its purview, as the subject does, something from every division of medical science, this exhaustive treatise will ever remain an invaluable collection of data. It may be remarked also that many of the cases cited are of great usefulness as disciplinary lessons in deductive reasoning.

In the opinion of the reviewer, this book is destined to secure a very large sale, for it is one of the few that one finds pleasure in welcoming to the table. Logical, painstaking, and careful, it brings under the eye, within a modest compass, the latter-day teachings concerning the treatment of wounds, and while, owing to the nature of the subject, it is not likely to live forever, yet a long time will elapse before it will have a successful rival. As the book treats of the topic now uppermost in the minds of surgeons, it is most timely for those who wish to keep pace with the progress of this branch of medical science without the weary task of searching the journals for the facts here really collated to their hand. Moreover, unless one is somewhat skilled in such researches, he will find himself burdened with much rubbish, which it will puzzle him to turn to account; so that, when a field has been found gleaned by so skillful a hand as Dr. Pilcher's, the labor might as well be saved, and the result accepted. Without any question, this is one of the best books on the treatment of wounds yet published, and, although we notice an omission or two, yet they are so trifling that it would seem invidious to detract from the merits of the work by mentioning them.

This classical work has been subjected to most thorough and painstaking revision, and many additions have been introduced without materially altering the form of the book. It still has its familiar book. Professor Thane's revision is seen in the first volume, in which the figures show the blood-vessels colored. A chapter has been added on superficial and topographical anatomy. The new work on the second volume has been done largely by Mr. Schäfer, embracing the histology and special anatomy of the viscera, and Dr. Thomson has contributed the entire chapter on embryology. Considerable changes have been made in the histological matter and in the section on the central nervous system, and Dr. Thomson's chapter on embryology may be called a treatise in itself, in which deserved prominence is given to Foster and Balfour's researches.

There are several text-books that may serve well enough for those who simply aim at memorizing the dry facts of anatomy, but Quain's is the only work we know of in the English language from which the science of anatomy can be learned. It has always been a favorite with students who were really fond of the study.

So far as the body of the work is concerned, we are unable to see that this is an improvement on preceding editions, although it presents a handsomer appearance than former American editions. In view of all that has been published of late years on the topographical anatomy of the pelvic contents in the female, it is somewhat surprising that such a cut is retained in the book as that which is to be found on page 892. Mr. Holmes' introduction, on General Anatomy and Development, is the gem of the volume, and the incorporation of Mr. Holden's "Landmarks, Medical and Surgical," certainly adds to its practical value.

Mr. Hill's little book is somewhat pretentious, for it includes not only bandaging proper, but the treatment of fractures and dislocations, directions for administering ether and chloroform, and "for using other surgical apparatus," and a chapter on surgical landmarks. There is little change from previous editions, nor does there appear sufficient reason for extracting these topics from the regular treatises on minor surgery; but, as the book has reached its fifth edition, it is evident that, for some occult reason, it has met a popular want. The chapter on Surgical Landmarks is especially good. The illustrations are fairly well done, although it would appear that a more recent pattern of aspirator might have been figured than the one on page 190.

In this book there is no attempt to go beyond the scope of the topic indicated in the title, "The Roller Bandage." Directions are given clearly and in full for the application of all
varieties of bandages that may be made from a roller. There are seventy-three illustrations, most of which, unfortunately, do little credit either to the artist or to the engraver. This is the more unfortunate, as the text is carefully written.

BOOKS AND PAMPHLETS RECEIVED.

Extensive Fracture of the Pelvis, and other Severe Injuries to the Body: Recovery. Suit brought to Recover Fee; Malpractice set up as an Offset; Judge’s Charge to the Jury; Judgment for the Plaintiffs. Reported by J. E. Markle, M. D., Winchester, Ind.

Delayed and Non-Union of Fractures. By N. Sann, M. D., Milwaukee, Wis. [Reprint from the “Weekly Medical Review.”]

Infusion of Jequirity, or Licorice Bean, in Invertebrate Pan-nus, with a Report of Several Successful Cases. By Edward S. Peck, M. D., Surgeon to the Eye and Ear Department of the Northwestern Dispensary, etc. [Reprint from the “Medical Record.”]

A Case of Severe Purulent Inflammation of the Middle Ear with Restoration of the Drumhead; Consecutive Dentalgia without Caries. By Edward S. Peck, M. D., Ophthalmic and Aural Surgeon to Charity Hospital, New York. [Reprint from the “Independent Practitioner.”]

An Examination of Some Controverted Points of the Physiology of Voice, especially the Registers of the Singing Voice and the Falsetto. By T. Wesley Mills, M. D., L. R. C. P., Assistant of the Professor of the Institutes of Medicine, McGill University, Montreal. [Reprint from the “Journal of Physiology.”]

Correspondence.

LETTER FROM VIENNA.

The Lecturers in the Winter Course.—Billroth’s Clinic.—Obstetrics and Gynaecology.—Pathological Anatomy.

VIENNA, October 20, 1883.

One need only glance at the bewildering array of notices upon the hospital bulletin-boards to infer that the winter work has fairly begun. New courses are starting up on every side, until one is fairly appalled at the possible number of specialties into which medicine may be divided. But while these increased opportunities for a choice are apparently one of the greatest advantages of Vienna, in reality they are often a serious embarrassment to the fresh-comer, who finds it hard to decide which courses will be the most profitable. It is very unfortunate that every American must learn by experience, and probably throw away not a little of his time and money, before he discovers what instructors are really worth listening to. A man’s friends can help him to some extent, but so diverse are the ideas with regard to different lecturers that it is impossible to judge of their merits until one has heard for himself. But, in general, it is pretty safe to infer that if there is anything good to be picked up there will be a crowd of our countrymen on hand. On the contrary, it is rather amusing to see some men listening daily to very ordinary lectures, and taking careful notes, simply because the lecturer is a German professor, and the place Vienna, forgetting that they have heard just as profitable (and more intelligible) discourses at home. It takes a man several months here to discover that, the more an instructor inclines toward didactic lectures, the less valuable is his course.

The semester has opened favorably, with a fair number of students. There are but few changes in the faculty. Arti has retired on a pension, being succeeded by Stellwag, and the later’s place is filled in turn by Professor E. Jaeger. Of the different departments, that of Professor Kaposi is, as usual, popular, especially with Americans.

Neumann, in syphilis, and Monti, at the Poliklinik, in children’s diseases, have a good following. Ullmann, in gynæcological and urino-urinary diseases, is always a popular lecturer with foreigners, and deservedly so, not only because of his lucid style, but from the practical character of his instruction.

I have seen Billroth operate—did I say seen? I stood behind a crowd of students and caught occasional glimpses of that celebrated surgeon, almost swallowed up in the throng of his assistants. The German idea of an operating theatre would indeed be a peculiar one if the narrow, cramped, ill-ventilated rooms in the hospital were to be taken as a type. Not to speak of the impossibility of the hapless spectator seeing anything of the operation (such is the number and such the eagerness of the assistants), the foul air forces him to think that bacteria are living realities. I would not lead your readers to infer that I am trying to depreciate Vienna surgery. All who have been here will acknowledge that its study must be pursued under some difficulties. As to gynaecology, I am not prepared to say much from personal experience. The courses, as everybody knows, are conducted at the hospital and dispensaries, on the same general plan as in New York. This is not the place in which to refer to treatment. We, in America, have an idea that our peculiar methods are not known, or, if known theoretically, not properly applied by the Vienna school. To what extent this is true I hope to be able to state at length hereafter. One thing is certain, that there is no divorce of gynaecology and obstetrics, but the all-important prophylactic against diseases of women, care during confinement, is thoroughly understood and appreciated. Professor Carl Braun holds a clinic daily, at which he either operates or shows interesting cases. Most of his laparotomies are performed in the public lecture-room.

It is hardly necessary to dwell upon the topic of Vienna as a place for pathological study, since it is generally known what the opportunities are. The material is certainly enormous, and it is rather significant that few men come here with the express purpose of studying morbid anatomy. There are some fair demonstration courses, but the difference between a careless and a careful autopsy represents the essential difference between the pathology of Vienna and that of Berlin. A beginner will not find it to his advantage to “form his style,” so to speak, by watching post-mortems here. After all, it is difficult to characterize Vienna as a center of medical study. Opinions with regard to its advantages are as various as the students who come hither. Some of the more experienced, who, by reason of long residence and liberal donations, have come to enjoy peculiar privileges with the assistants, think that it is unsurpassed, while others among the uninitiated (or more economically inclined) are not so enthusiastic. As I said before, every one must see and judge for himself.
THE ANNUAL REPORT OF THE SURGEON-GENERAL OF THE ARMY.

A pamphlet of very moderate dimensions suffices for a synopsis of the work of the medical corps of the army during the fiscal year ending June 30, 1883, but it is ample when we take into account the great volumes of other matter that are issued from the Surgeon-General's office at short intervals, embodying the more detailed scientific data of the office. The document is dated October 15th, and is signed by Acting Surgeon-General Huntington, although, as he states, its preparation was actually completed by the late Surgeon-General Crane.

A summary of the sick-list reports shows that the proportion of men under medical treatment during the year was greater than during the preceding year, and also greater than the average decennial rate. The death rate was ten in a thousand of mean strength, being equal to that of the previous year, but less by two and seven tenths in a thousand than the average for the preceding decade. Nevertheless, the proportion of deaths from all causes to the number of cases treated is stated to have been increased, both over that of the year before and over the average for the decade. Unless we misinterpret the statements made in the report, there is a discrepancy in these figures which we are unable to reconcile with the possibilities of the case. They relate solely to the white troops, but those in regard to the colored troops are of the same general purport.

Diseases of the respiratory organs were the cause of the greatest number of deaths, and it is to be regretted that their prevalence has to be imputed in great measure to the insufficient ventilation of barracks and dormitories. Notwithstanding the fact that only two fatal casualties from actual warfare were reported during the year, injuries stand second on the list of causes impairing the effectiveness of the army, far exceeding in proportionate number those for the German and the British armies, and going to show the extent to which our soldiers are subjected to laborious and dangerous employments in the line of duty. Perhaps this very fact, in connection with the trifling share of garrison duty in and about large towns that falls to his lot, accounts in great measure for the freedom of the American soldier from venereal diseases as compared with the men of the British army. However, the contrast is quite striking, the rate being one hundred and seven in a thousand higher for the British army than for our own—and that, too, in spite of the fact that the British medical officers report only cases in which hospital treatment is given, whereas our own reports cover all cases in which treatment of any sort is employed. Very much to the credit of the colored troops, it is noted that the proportion of sickness from the use of alcoholic drinks is small among them.

On the other hand, the blacks seem largely affected with diseases of the nervous system, the preponderance of which in their ranks is set down as unexplained.

Four cases of small-pox were reported during the year. Small as this number is, it is just twice as large as that reported in the German army (of a mean aggregate force of over three hundred and twenty-seven thousand officers and enlisted men) for the two years 1879 to 1881. The Surgeon-General properly emphasizes this comparison by calling attention to the greater exposure to the usual sources of infection in the German army than in our own, stationed as the former is in thickly populated communities; and, with equal propriety, he calls for the thorough enforcement of revaccination in our own army.

It is to be hoped that Congress will not long turn a deaf ear to the appeals that have been made for a fire-proof building for the library of the Surgeon-General's office. The pressing necessity for such a provision is again urged, and it is pointedly set forth that great apprehension is felt for the safety of a large number of documents the loss of which would add countless difficulties to the work of the Pension Bureau. As a temporary expedient—only temporary, let us hope—nearly six thousand volumes of hospital registers and death and discharge registers have been placed in truck cases on the ground floor, so arranged that, in case of danger, they can be run out into the street, provided "sufficient warning can be given." By such a slender thread hangs the preservation of data indispensable to the nation's policy of keeping faith with those who have suffered in its behalf! Add to this the loss that would follow the destruction of the invaluable collection of medical books in the library—the force of which would fall, as we have heretofore pointed out, not on the army medical corps alone, but on our whole people—and the supineness of Congress seems inscrutable.

EXPERIMENTAL THERAPEUTICS IN LONDON.

An incident has lately happened in London that a few bigots seem to be doing their best to torture into a pretext for the wholesale arraignment of the medical profession for reckless and inhuman drugging. Dr. Sydney Ringer and Dr. William Murrell, two men to whom the therapeutics of the present day owes some of its most precious resources, recorded in a recent issue of the "Lancet" the results of certain experiments they had been making in the use of nitrite of sodium as a remedy. Among the trials that were made of the drug was its administration to a number of hospital patients.

The beneficial action of several of the nitrates in certain painful and dangerous affections—an action which these two gentlemen have been largely instrumental in establishing—taken in connection with the recent recommendation of the sodium nitrite by an independent observer, certainly appears to have furnished a sufficient warrant for testing the latter agent in a systematic manner. It seems, however, that its action upon the hospital patients in question was quite variable. In some instances it gave rise to sensations so unpleasant that the patients refused to continue its use, even stating their belief
that death would be the result of another subsection to its action.

There is nothing to show that Dr. Ringer and Dr. Murrell failed to observe the precautions proper to be taken in the employment of drugs concerning the effects of which little is known. Indeed, there is positive evidence that such precautions were fully observed. Unfortunately, however, the published report of the trials they had made of it contained an account of the impression its action made on the minds of the patients in question. That was enough for a few agitators who class themselves among the anti-vivisectionists. At once they set up the cry in the newspapers, and through other channels that suited their purpose, that this incident was only an example of the usual unfeeling and reckless way in which physicians were wont to treat poor hospital patients.

Now, if there is one thing against which, more than another, the man of ordinary ignorance rebels, it is the idea of being "experimented on" in a medical way. It is easy to see, therefore, what a lever the agitators found ready at hand. The accusation could easily have been refuted in the minds of the intelligent, even if there were anything to show that they were inclined to entertain it; but, when it comes to the pass that the medical officers of the hospital concerned see fit to meet and formally express their disapproval of such experimental inquiries, as was done in this instance, it may well be feared that the retort will be made, quia svecina s'excuse. It may have been unwise to allow the report to appear in the precise form given to it, but certainly the profession will sustain Dr. Ringer and Dr. Murrell on the main issue, and, for our part, we can only hope that the annoyance to which they have been subjected will not lead them to abandon the pursuit of experimental therapeutics in disgust.

**THE CRUISE OF THE CORWIN.**

In accordance with a resolution passed by the House of Representatives at its last session, requesting copies of documents in the possession of the Treasury Department containing medical and scientific notes and observations made on the cruises of revenue cutters during the year 1851, the department has lately issued a quarto volume, of moderate thickness, giving such notes as were made on the cruise of the steamer Corwin in the Alaskan and northwestern Arctic waters. Valuable observations on the plants and birds of the regions in question are contributed by Mr. John Muir and Mr. E. W. Nelson, and Mr. Tarleton H. Bean adds a list of fishes known to exist in the Arctic Ocean, north of Behring's Strait. But our readers will be more particularly interested by Dr. Irving C. Rosse's medical and anthropological notes on the native inhabitants.

Dr. Rosse furnishes a good deal of evidence that the Esquimaux are by no means an athletic or warlike race. As a general thing, they were found quite inferior to the Corwin's company in muscular development. It seems that, when they are attacked with sickness of any considerable gravity, there is a marked tendency to adynamia, and the resident practitioners find it necessary to employ supporting measures freely, for the most part the administration of quinine. Dr. Rosse had the opportunity of observing several cases of an endemic disease in which this feature of prostration was prominent. The affection was characterized, he tells us, by pronounced dyspnoea, bronchophony, imperfect aeration of the blood, cough, expectoration, pain, insomnia, and great physical and mental depression. At the outset it often happened that the patient had made up his mind that he must die, and in that condition it was almost impossible to impart the least ray of hope to him. Dr. Rosse regrets that no opportunity was offered for a post-mortem examination, but gives his impression that the morbid anatomy may have been different from that of pneumonia as it is known in temperate climates. He leans to the opinion that, on returning from a sojourn in the Arctic region, the voyager is more disposed to suffer from meteorological changes than he was before leaving home.

There are many points of great interest touched upon by Dr. Rosse, and his style of writing makes the story attractive.

**A PREPARATORY SCHOOL OF MEDICINE.**

A novel medical school is to be started in London, we learn from the "Medical Times and Gazette," being a preparatory school of medicine and natural science, under the auspices of the West London Hospital. This institution has, of course, the usual facilities for imparting medical instruction, and, as it is conveniently near the South Kensington Museum, the natural sciences can readily be taught in a branch of the school.

The particular objects aimed at in the medical department are stated to be the following: 1. To give, in a more complete and systematic manner than has heretofore ever been attempted, all the advantages of a year's pupilage at a first-class provincial infirmary or county hospital. 2. To give thorough and practical instruction in natural science, such as is to be carried up to the standard of the preliminary scientific (M.B.) examination of the London University. 3. To give intending medical students an early insight into medical work, so that they may, without needless loss of time or money, be able to judge whether or not they have chosen the right profession.

The instruction in medicine and surgery proper is to be purely elementary, but materia medica, osteology, and the subjects taught in the science school will be gone into with greater detail, the latter including mechanical philosophy, physics, chemistry, botany, zoology, and drawing.

The managers of this enterprise are to be credited with some ingenuity when they speak of the South Kensington Museum as "conveniently near" the hospital, although it takes a ten-minutes' journey by the underground railway to get from the one to the other. We wonder their fertility of resources did not suggest to them that it would be a taking piece of policy to term the institution a medical Kindergarten.

**MINOR PARAGRAPHS.**

**THE NEW SURGEON-GENERAL OF THE ARMY.**

On Friday of last week the President appointed Assistant Surgeon-General Robert Murray to be Surgeon-General of the
army, in place of the late Surgeon-General Charles H. Crane. Surgeon-General Murray entered the medical corps of the army in the year 1846, as an assistant surgeon; in 1851 he was made captain; in 1860, major; in 1865, brevet lieutenant-colonel and brevet colonel; and in 1876, colonel. His brevets were earned by faithful and meritorious service during the War of the Rebellion. While Assistant Surgeon-General he served as the Medical Director of the Department of the East, on General Hancock's staff.

Our Washington correspondent, under date of October 13th, mentioned Dr. Murray as one of two the most prominent candidates for the succession to the office of Surgeon-General. It is not to be supposed, however, that Dr. Murray's candidacy was at all obtrusive; he was simply the senior officer in the regular line of promotion. By appointing him the President has followed the principle—a safe one in the majority of instances—of a regular succession, and has avoided the appearance of partiality that might have attached to the choice of any one of the other candidates in the field. We look to see the affairs of the medical corps of the army well administered by Surgeon-General Murray.

THE LONG ISLAND NUISANCES.

After somewhat prolonged consideration—or, at least, after the lapse of a long time supposed to have been devoted to consideration—of the various sources of the abominable odors that pervade the country around Hunter's Point, the State Board of Health is reported to have adopted a report which includes certain recommendations to the owners of a starch factory. The board advises that none of the waste products be allowed to enter the adjacent creek or any of the neighboring waters, but be led into a vat, there to be subjected to chemical treatment.

It needs no great stretch of one's natural powers of inference to divine that, so far as the starch-makers are concerned, the board's advice lacks the charm of novelty. Perhaps this fact may account for the observation reported to have been made by them: "We shall respectfully consider the recommendations, which, however, are not mandatory. They will not affect us. It would be impossible for us to adopt them." Meantime, an association of the citizens of Sea Cliff undertakes to see to it that the board's report shall become mandatory in case it receives the Governor's approval.

TYPHOID FEVER AND THE ORANGE COUNTY DAIRYMEN.

One of the daily papers having published a letter from a medical man living in Goshen, containing pointed allegations of negligence on the part of the dairymen of that town in the disposal of refuse matter, which, the letter asserts, is in many instances allowed to percolate into the well or to mingle with the water that the cows drink, the milk-producers have chosen to make a show of indignation at what they are pleased to regard as a charge of deliberately and maliciously poisoning their commodity. Of course, this is a ridiculous stand for them to take. It is to be hoped that the facts in the case will be made the subject of a searching investigation. The ordinary rustic is apt to pool-pooch the matter of drainage. He should be made to understand that it is not his opinion we want, but his compliance with the commonest demands of decency and the laws of health.

ASYLUM MISMANAGEMENT.

Accounts of neglect and brutal treatment of the inmates of asylums for the insane are getting to be unpleasantly common. The latest story of the sort that has come to our knowledge relates to an asylum in Dayton, Ohio. We are constrained to suppose that the statement is exaggerated, for it seems incredible. The report is that a bath was being administered to a patient, and that the attendant left the man in the bath-tub to go into another room for his clothes. During his absence the hot water was turned on, and when he returned he found the man boiled to such an extent that "the cooked flesh stuck to his fingers"—and yet the man was alive. In view of the length of time usually required for the cooking process, we wonder whether the apartment to which the attendant had to go was also in Dayton, or in an adjoining town. The affair is said to have happened early in the evening, and no physician visited the sealded man until noon the next day.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending November 27th, 1883:

The New York Academy of Medicine.—At the next meeting, to be held Thursday evening, December 6th, Dr. T. Guilhard Thomas will read a paper on "The Treatment of Puerperal Septicemia."

The New Jersey Sanitary Association will hold its ninth annual meeting in the Senate Chamber, at Trenton, on Thursday and Friday, December 6th and 7th. The order of business is as follows: Thursday—afternoon session, at 3.30 o'clock: "Methods of Sewage Disposal without Discharge into Streams," by Mr. J. J. R. Croes, of New York (the discussion to be opened by Mr. C. F. Wingate, of New York). "Malaria," by Dr. T. W. Harvey, of Orange (Dr. H. P. Godfrey, of Camden, and Dr. E. M. Hunt, of Trenton, to take part in the discussion). Evening session, at 7.30 o'clock: "Methods of Popularizing Sanitary Information," being the annual address by the president, Mr. J. C. Bayles, of East Orange. "Domestic Wells and Cisterns; Best Methods of Construction," by Dr. J. W. Pinkham, of Montclair (the discussion to be opened by Mr. George P. Olcott, of Orange). "Upon the Agencies, both Natural and Artificial, affecting the Purity of the Passaic River, above and below Paterson," by Professor A. R. Leeds, of Hoboken. Friday—session from 9 a.m. to 1:30 p.m.: "School Hygiene" (report of a committee, by Professor H. B. Pierce, of New Brunswick; paper, by Professor James Green, of Long Branch; "Physical Exercises in Schools," by Professor J. M. Watson, of Elizabeth). "Appliances for Raising and Distributing Water," by Professor C. F. Brackett, of Princeton. "Filtration," by Professor George H. Cook, of New Brunswick (the discussion to be opened by Mr. Edward Dunn, of Newark). "Nuisances Incidental to Manufacturing," by Dr. J. Mortimer Brush, of Bergen Point (the discussion to be opened by Mr. William Phillips, of Newark). "Reports from Localities." "General Discussion." Election of Officers.

The Paris Faculty of Medicine.—The assignments of the agrégés for the session of 1883-'84 are as follows: Internal pathology, M. Landouzy; external pathology, M. Richet; physiology, M. Richet; pathological anatomy, M. Raymond; obstetrics, M. Badin; physics, M. Gariel; chemistry, M. Henniger;
natural history, M. Blanchard. It is said that M. Pajot has been nominated to succeed M. Depaul as professor of obstetrics.

The French Academy of Sciences.—The vacancy caused in the section in medicine and surgery by the death of Baron Cloquet was filled on the 12th of November by the election of Professor Charcot. There were three candidates: M. Charcot, M. Sappey, and M. Hayen. M. Charcot received forty-six of the fifty-eight votes cast, and M. Sappey received twelve.

Trichiniasis and American Pork do not seem to be so intimately connected with each other, from the European point of view, as they have seemed in the past. A committee of the French Chamber of Deputies has had its attention drawn to the fact that the recent outbreak in Saxony was occasioned by German pork, and it is now thought likely that the French decree, prohibiting the importation of pork from America, will soon be revoked.

"The Medical Metropolis of the United States is now medically alive," says a Philadelphian correspondent of the "Maryland Medical Journal." In the same letter we find it stated that Dr. H. C. Wood's "Therapeutics" are going to be translated into Italian.

OBITUARY NOTES.

John Bell, M. D., of Chester, N. H., died recently, at the age of fifty-two. He graduated from the Academy Department of Dartmouth College in 1833, and from the Medical Department of the University of Pennsylvania in 1834. In 1861 he was commissioned Assistant Surgeon in the United States Army, from which he resigned June 24, 1867. In 1865 he received the brevet rank of Captain and of Major for faithful and meritorious service during the war. He had practiced his profession in Kingston, Derry, Dover, and Chester, N. H., and in New York City.

Professor Francesco Cortese, formerly the professor of surgery in the University of Padua, and afterward surgeon in the Italian army, with the rank of major-general, died in Rome on the 24th of October, at the age of eighty-one years. The Italian journals speak of him as illustrious in science, an eminent patriot, and an unpretentious philanthropist.

Letters to the Editor.

ANTIPYRETTICS IN TYPHOID FEVER.

Boston, 24 Marlboro Street, November 26, 1883.

To the Editor of the New York Medical Journal:

Sir: I believe the more one sees of typhoid fever, and the better acquainted one becomes with the literature of the subject, the less is the disposition to dogmatize about it, or to be very ardent about any pet theories in regard to the etiology or treatment of the disease. I have, therefore, no such design upon your valuable space. But I have just read a paper in your last issue, by Professor Beverley Robinson, concerning the use of antipyretic agents in typhoid fever, which seems to have been partially evoked by a report of some cases by Dr. F. W. Draper and myself, in a recent issue of the "Boston Medical and Surgical Journal," thus referred to in a foot-note of Dr. Robinson's paper: "Any one who shall (sic) read with an unbiased mind the cases and discussion here reported will scarcely be tempted to repeat the experiments of Drs. Shattuck and Draper."

Now, Mr. Editor, having already granted in the report that the experiments with kainine could very easily be improved upon, I will not insist upon their being repeated, and I merely wish to say that I should regret the publication of the cases if either the cases themselves or Dr. Robinson's reference to them should prevent others from trying kainine. "It is not so devil as it is black"—in fact, I think, with moderate precautions, it will be found an unusually safe thing to administer.

The depressing effects in these cases at the Boston City Hospital were more marked than in the cases of its use reported from Germany which I have seen. I suspect it is possible that may indicate a less pure preparation, a difference of action resulting similar to that shown by salicylic acid from oil of wintergreen, and salicylic acid from carbolic acid.

Although apprehensive of the wisdom pervading Sir William Jenner's address before the Midland Medical Society, to which Dr. Robinson alludes, I still do not hesitate, in certain cases of continuous high temperature, to resort to antipyretics circumstantly, and should be glad to have a better one than we now possess. Kainine should be allowed a fair chance to prove its claims, and I see, by the discussion following Dr. Dechafte's paper before the New York Academy of Medicine, that it is in process of having it in New York.

Very respectfully yours,

George B. Shattuck.

THE NEW YORK INFANT ASYLUM.

New York, November 27, 1883.

To the Editor of the New York Medical Journal:

Sir: The extract from the minutes of the Executive Committee of the New York Infant Asylum, published in your journal of November 24th, by Richard B. Kimball, secretary, concerning the meeting of October 6th, states:

"Dr. Foster submitted the report of the sub-committee, appointed September 29, 1883, Messrs. Foster, Burrall, and Goodridge, which was read by the secretary and ordered placed on file."

We wish to call attention to the fact that preceding this action the minutes contained the following:

"Colonel Willis then moved to lay the resolution of September 29th, just reconsidered, on the table, which was seconded. After discussion by Dr. Foster, the motion to lay on the table the resolution of September 29th, appointing a sub-committee of Foster, Burrall, and Goodridge, was laid on the table. Ayes—Bates, Bell, Kimball, Turner, and Willis. Nays—Foster." Is it not clear from the foregoing that our statement, published in your journal October 27th, concerning the action of the Executive Committee toward the chairman of this sub-committee, is strictly in accordance with facts? When Dr. Foster submitted the communication prepared by the sub-committee, that committee had already been discharged by laying the rescinded original motion on the table, and there was no longer either committee or chairman.

We are requested by Dr. Joel Foster to add that his reported statement to the effect that the measles had recurred "twice, thrice, four, and five times in the same patient," was made upon the authority of the resident physician.

F. A. Burrall, M. D.,
Henry D. Nicoll, M. D.

THE PREGNANCY OF THE NEW YORK MEDICO-LEGAL SOCIETY.

581 Fifth Avenue, New York, November 26, 1883.

To the Editor of the New York Medical Journal:

Sir: Will you kindly permit me, through your valuable journal, to inform my friends that I am not a candidate for the

* "Portuguese Grammar."
presidency of the Medico-Legal Society at the coming election. I was placed in nomination while absent from the meeting.

The office of president for the ensuing year belongs, without question, on the medical side of the society, and while I appreciate the distinction it conveys—if fairly won—there are others who have been longer in and who have done more for the society than myself, and who have a prior claim to the honor.

I am very truly yours,

M. H. Henry, M. D.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

A STATED MEETING WAS HELD NOVEMBER 13, 1883, THOMAS M. MARKOE, M. D., PRESIDENT, IN THE CHAIR.

DOUBLE DISLOCATION OF THE PATELLA.—DR. F. LANGE presented a boy, eleven years of age, who illustrated dislocation of both patellae outward in every attempt to flex the knee joints. It was difficult to determine whether or not the abnormality was congenital, because it was not noticed until quite late. It had been simply observed that the child was not able to walk as well as other children, and that his knees were exceptionally thickened, and became tired easily. Dr. Lange saw the boy about the first of June last, when he was pale and nervous, and sometimes fainted. At present, when he walked, he lifted his pelvis and tried to keep the thighs as vertical as possible, thereby avoiding flexion at the knee joint. The extensor muscles of the thigh were atrophied somewhat. Every time the joints were flexed the patella, which was abnormally small and flat, became completely dislocated, and turned so that its internal edge was directed forward, and the condyles of the femur could easily be marked out. There was a strong inward rotation of the femur during flexion. On the other hand, he could extend the limbs completely, only with difficulty; that is, they were stretched to about a right angle without liability, and then he made a peculiar rotary movement with the heel on the table and pushed the entire limb in order to complete the extension. If the patella was kept in position he was unable to flex either joint. The hip joints were normal. He had been wearing an apparatus, but without improvement. A complete cure probably could not be obtained.

LIGATION OF THE COMMON Iliac Artery for Anuria from the External Iliac, performed through the Peritoneum.—Dr. Lange also presented a patient with the following history: He was thirty-seven years old, a musician. He admitted having had gonorrhea, but denied syphilis. He had had “alcers in the throat” about six years ago, and still presented a hyperplasia of the right tibia probably of a syphilitic nature. In July, 1882, he first noticed pain in his left leg, about the knee, which appeared quite sudden and caused intense lameness for a time. In this way he suffered til January, 1883, partly in hospitals, partly at home, but never entirely free from an uncomfortable feeling or soreness in the knee joint. It was said to have been swollen, and was treated for some time by an immobilizing dressing. A puncture was also at one time intended, but was omitted on account of spontaneous improvement. The patient said that all through that time he had a lump about as large as a pigeon’s egg in the left inguinal region. From January till May, 1883, he felt well, but in May he suddenly fell on account of absolute lameness of the left leg, so that he had to be carried home, where he improved very soon. Such fits without any pain were repeated about three times within the next months. In July, Dr. Lange saw the patient first. Several weeks previous to that he had been subject to severe suffering. The lump in his left groin, which so far had attained about the size of a hen’s egg, had increased rapidly, without apparent cause. Numbness and a feeling of cold had affected the limb, which became weaker and weaker, and a more or less severe pain along the anterior aspect of the thigh persisted. On the 29th of July a pulsating tumor, with all the characteristics of an aneurysm, occupied almost the whole iliac fossa, causing the abdominal wall to protrude above Poupart’s ligament. Its upper boundary ran from the anterior superior spinous process toward the umbilicus, ending about an inch below the latter, in the middle line, which formed about its mesial outline. A spindle-shaped process of the tumor extended in the direction of the femoral artery below Poupart’s ligament. But nowhere could arterial pulsation be detected in the limb, which was cool and had a bluish hue.

Ligation of the common iliac artery was resolved upon as the only procedure worthy of consideration, in view of the rapid growth of the tumor within the last few weeks; and it was decided to perform the operation through the peritoneum on account of the difficulty which must have offered itself in this case to the customary retro-peritoneal way of reaching the vessel. The patient was prepared by rest, diet, laxatives, and the internal administration of bismuth, and the operation was performed under strict antisepsis precautions, without any serious difficulty, with the able assistance of Dr. McBurney and the house surgeon at Bellevue Hospital, on the 26th of July.

A long incision was made, beginning, as could be seen from the scar, 1½ inches above the umbilicus, and reaching downward about 6 inches. All the intestines were removed from the upper aperture of the pelvis and wrapped between large flat sponges outside the abdominal cavity. An unusually large spectrum served as a good retractor and reflector, so that the second step in the operation, the ligation of the artery, was executed with safety and ease. The ligature was of silk, and was cut short. It could be ascertained that the artery was lifted from its normal bed by the blood-sac, over the mesial aspect of which it could be traced for some distance.

No bad symptoms followed the operation, and the vitality of the limb remained unimpaired excepting a small cutaneous necrosis on the great toe. The temperature was never very high, so far as he remembered, only once above 103° F., at the time when the first movements from the bowels took place, and partly, perhaps, due to a cystitis in consequence of catheterization. The patient was discharged about five weeks after his admission. At that time a slight diminution of the tumor had already taken place, and a faint pulsation in the main arteries could be detected. Dr. Lange did not know whether that was not an error, because he was unable to discover any pulsation at the present time. The temperature of the limb had now become more nearly normal, yet it was somewhat less nourished, and was paler in color than the right one. Its sensibility was normal, but its reflex irritability was diminished as compared with that of the right limb. The pain the patient complained of formerly had ceased, and the tumor had shrunk to the size of a good-sized orange.

Compound Committted Fracture of the Skull; Absence of Brain Symptoms; Healing by First Intention: Recovery.—Dr. Charles McBurney presented a child, five years of age, who received a compound comminuted fracture of the skull on the last day of October. He was operated upon, under Dr. McBurney’s direction, a few hours after the receipt of the injury, by Dr. Fuller, House Surgeon at Bellevue Hospital. There was marked depression of bone, but there were
no brain symptoms. There was a ragged wound about an inch in length at the seat of the injury, and the operation was begun by extending this wound about an inch in each direction, and a portion of bone about an inch in diameter was removed, made up of many small fragments. The dura mater was not injured. Before and during the operation the parts were irrigated with bichloride-of-mercury solution, the edges of the wound were trimmed, and the aponerotic layer, together with the perios-
team, was brought together by one deep row of sutures and the skin layer by another. No drainage-tubes were used. The wound was dressed with iodoform, prepared cotton, and gauze, and a starch bandage was applied. The dressing was not removed until the eighth day after the operation, when the wound was found in the condition of complete union, as now seen. Not a single unfavorable symptom developed during the pro-
gress of the case, and no dressing was required after the first one was removed.

OSTEOSARCOMA OF THE LOWER JAW.—Dr. McMenemy also presented a colored boy, thirteen years of age, who had a tumor on the side of his face and neck, which was especially notable on account of its size. The tumor was said to have had a growth of nine years, and to have begun in the lower jaw, from which time, according to the account, it had quite steadily increased in size up to the present date. According to the history, which was exceedingly meager, the tumor was removed about three years ago, but Dr. McMenemy had been unable to obtain any of the details of the operation. The growth seemed to involve the lower jaw and possibly the upper jaw, and consider-
ably narrowed the face and cavity of the mouth. Its circumference was twenty-five inches, and it measured eighteen inches from side to side. There had been an average growth of two inches during the last six months.

ARTERIO-VENOUS ANEURYSM OF THE COMMON CAROTID AR-
tERY AND THE INTERNAL JUGULAR VEIN.—Dr. L. A. Stimson presented a patient, twenty-five years of age, who had a tra-
umatic communication between the common carotid artery and the internal jugular vein, produced by a stab with a penknife in February, 1882. A profuse hsemorrhage occurred at the time of the injury, but it was arrested within two hours, and did not return. At the end of a week the wound was healed. The neck, however, remained swollen, and in the following June, after a spree, a lump appeared in the throat, the face and neck became swollen, there was some difficulty of breathing, and the patient consulted a physician, who called his attention to a peculiar thrill in the neck. The acute symptoms soon subsided, and in the following August the man resumed work, but soon found that it interfered with his comfort, produced a choking sensation, vertigo, etc., and he abandoned it. Since that time he had consulted several physicians, and had been uniformly ad-
vised to have nothing done. He came to Bellevue Hospital com-
plaining of gastric distress, a choking sensation, vertigo, dimness of vision in the left eye, and loss of hearing in the left ear. There was considerable exaggeration in his account of all these symptoms. At that time, however, there was a marked thrill over the left side of the neck down to the clavicle, with a loud, double sound. Dr. Stimson finally decided to operate, with the intention at first of placing two ligatures upon the vessel, but finally decided to apply only one, and that upon the proximal side of the common carotid artery, trusting that the recurrent stream from the distal side of the opening would not be suffi-
ciently strong to give rise to any discomfort. The operation was performed on the 8th of October. An incision was made so as to expose the artery above the omoloid muscle, but the tissues overlying the vessel were found so thickened at this point that the incision was prolonged downward, and the artery tied below the muscle. A drainage-tube was introduced and a dress-
ing applied. The dressing was changed on the fourth day, the drainage-tube was removed, and from that time recovery was rapid. There was no rise of temperature above 100° Fahr., ex-
cept once, and then only for a few hours, when it sank and re-
ained normal. The thrill, which ceased at the time the lig-
ture was applied, was perceptible at the first dressing, but it was very slight, and it could now be felt, but in very much dimin-
ished force as compared with that which was present before the operation was performed.

During the progress of the case after the operation, two ac-
cidents occurred. The first was on the tenth day. The man awoke from sleep with precordial anxiety and distress, and also distress in breathing, and was very much alarmed. He was quieted with a moderate dose of morphine, went to sleep, and suffered no further inconvenience. Dr. Stimson thought that the symptoms were due to disturbance in the pulmonary circu-
lation, consequent on the transmission of a small embolus de-
tached from the clot. Exactly where it came from, however, he was unable to say. Since that time the patient had had no return of a similar attack, but had at intervals had a peculiar distress, which would seem to indicate that probably the ex-
planation given for the first attack was incorrect.

The second accident occurred about the fourteenth day, when he complained in the morning of some loss of power in the right hand, with a moderate amount of dizziness, which disappeared in the course of two or three hours. He had not suffered from any inconvenience of a similar character since. Dr. Stimson thought that, undoubtedly, these symptoms were due to cere-
bral embolism.

PRIMARY EXCISION OF THE ELBOW JOINT FOR INJURY OF THE
ELBOW.—Dr. W. T. Bell presented a patient, forty-eight years of age, who fell three stories from a scaffolding, and received a compound fracture of the ulna, the olecranon being split into several pieces, and a vertical fracture, or fissure, between the condyles of the humerus. He had also a fracture of the ilium on one side. The operation upon the elbow joint was performed twenty four hours after the receipt of the injury. All the articular ends were excised, the entire olecranon, the head of the radius, and the condyles of the humerus, making in all about two inches of bone, the periostium being sawn as far as possible. The limb was dressed in the right-angled position, and healed, after an attack of cellulitis, in five weeks. Peat and car-
abolic-acid dressings were used eight months after the operation. The patient had very little power of flexion, but he was able to lift considerable weight with the limb, and the motion of the fingers was satisfactory. He could put his hand to his head. While the result was not all that might be desired, Dr. Bull thought it justified the operation, and that the limb, even in its crippled condition, was a great improvement on an artificial one.

Amputation of the Entire Penis for Epithelioma.—Dr. Bull also presented a patient, aged forty-three, who came into the New York Hospital with epitheliomatous ulceration of the penis, for which the entire organ was removed down to the insertion of the corpora cavernosa into the pubic bone, the corpus spongiosum being divided just in front of the bulb. The specimen was presented. It was a curious fact that the patient traced his disease to the cicatrix of a chancreoid which he had had twenty years before. The growth itself appeared first as a wart, and gradually extended, and for ten years he had borne a great deal of pain from the ulceration and suppuration, and his general health had been much impaired before submitting to the operation. At the time the operation was performed the ulceration had extended back to within one inch and a half of the root of the penis, but the extremiti of the
The normal glans was intact. There was induration and enlargement of the inferior glands upon both sides, to the size of a horse-chestnut. In amputating the organ, Dr. Bull followed Demarquay's method. The penis was incised by two incisions, which started from just above its root, and joined on its lower surface to split the scrotum, and extended as far as the middle of the perineum. The corpus spongiosum was divided in front of the bulb, and detached from the corpora cavernosa, and the scrotum on either side dissected back. The attachment of the crus to the pubic arch was divided with scissors. The bleeding was not excessive, and was easily controlled with artery-clamps. The urethra was slit up along its roof and floor, and stitched into the edges of the wound at the peno-scrotal junction. A drainage-tube was inserted at the lower angle of the wound, and the edges were sutured with catgut. Peat and bichloride dressing was used. Primary union failed, and the wound healed by granulation in six weeks. A catheter was left in the urethra forty-eight hours. At the end of that time a chill occurred, and it was withdrawn. A bougie or sound was passed every day for a month, but none had been used for two weeks past. When the man was discharged, a No. 30 sound could be introduced without difficulty, and the same number could be used now.

With regard to the enlarged glands in the groin, Dr. Bull had intended to remove them, but, as the operation had already been prolonged and tedious, he decided to postpone their removal until a future date. Since then the induration had almost entirely subsided. The improvement in the patient's general condition had been perfectly satisfactory, and began immediately after the operation was performed. He was now obliged to urinate in the sitting posture. Dr. Bull thought that the wound would have healed more readily had the testicles been removed at the same time amputation of the penis was performed, but the patient declined to part with all his evidence of manhood.

(To be concluded.)

NEW YORK OBSTETRICAL SOCIETY.

A STATED MEETING was held June 5, 1883, Dr. C. C. Lee, President, in the chair.

OVARIAN CYSTOMA COMMUNICATING WITH THE RECTUM—Dr. William M. Polk showed a specimen, and related the history of the case. [The case will be published in a future number of the journal.]

Dr. James B. Hunter thought that ovarian cysts communicating with the rectum must be rare. He had seen one case in which such a communication had been suspected from the clinical history, but the patient was not long under his observation, and the question was not settled.

Dr. Joseph E. Janvrin had seen an instance of the sort, in which the cyst twice discharged its contents through the rectum. No operation was performed, as the patient was suffering with Bright's disease, of which she subsequently died.

Dr. William T. Lusk alluded to a case that had come under the observation of the late Dr. Peaclee, in which a large abscess, which had discharged through the rectum, was supposed before the patient's death to be an ovarian tumor.

OVARIAN TUMOR TREATED BY PARTIAL REMOVAL AND DRAINAGE—Dr. Polk also showed the uterus, broad ligaments, and rectum of a patient whose history was as follows: She was sixty-nine years old, and had had good health until a year and a half before, when a tumor made its appearance in the right iliac region. It increased rapidly in size until by its weight and bulk her health and comfort were seriously affected. When she was admitted into Bellevue Hospital the tumor was found to be ovarian. The uterus was pushed to the left and well down into the pelvis, the fundus resting against the lower margin of the left obturator foramen, imparting a feel of resistance to the left lateral region of the pelvic floor. The remainder of the floor was occupied by a fluctuating mass—the whole crowded down to the pelvic outlet. It seemed probable that the tumor was without a pedicle.

The operation was done March 1st. The tumor was emptied and turned out without difficulty, there being few adhesions. After cutting away the larger part of the sac, its cavity was found to extend between the folds of the right broad ligament quite to its base, so that the tissue intervening between the cavity of the vagina and that of the sac was barely a third of an inch in thickness—in fact, the bottom of the sac, as the specimen showed, was attached to the upper end of the vagina in Douglas's cul-de-sac, being thence reflected to the anterior wall of the rectum. All this portion was covered with a side-growth of papillomatous tumors, and near the upper edge of the broad ligament were several nodules having a suspicious resemblance to cancerous deposit. In view of these pathological products, enucleation was deemed preferable to any attempt at drainage. This was accomplished throughout the entire extent of the attachment, save a spot about as large as a half-dollar, situated partly on the anterior rectal wall and partly in Douglas's cul-de-sac. This was denuded with scissors, and seared with a cautery. The time consumed, over an hour, had seriously taxed the patient's powers. A drainage-tube was introduced, the end resting in Douglas's pouch, and the wound was closed; but the patient never recovered from the operation—she died of exhaustion on the sixth day.

Owing to the nature of the growths in the sac, it had seemed improper to follow the plan of stitching its walls to the abdominal incision, and treating it by drainage. That would have shortened the operation, but would have robbed the patient of the benefit of the permanent removal of tissue subsequently shown to be cancerous. The one spot at which denudation, but not entire enucleation, was accomplished was situated too deep to be brought up and stitched to the abdominal opening. The use of a drainage-tube was therefore all that was left.

It occurred to Dr. Polk that, in simple sacs, free from carcinomatous deposits, in which the bottom was so close to the vagina, and in which enucleation was difficult, an advantage might be gained by making a counter-opening into the vagina, stitching the walls, as usual, to the abdominal incision, and then passing a tube so as to secure drainage from both ends of the sac. There would be no danger of implanting the peritoneum in such a procedure, as the attachments of the sac above and below would isolate the tube.

TAIT'S OPERATION—Dr. Polk related two cases, and showed the specimens. In the first case the operation had been done three weeks before, and the patient was doing well. The indications calling for the operation had been well marked—for seven or eight years the patient had suffered from intense ovarian dysmenorrhea, but her general health was good, so that he had regarded the case as likely to furnish a good test of the value of the operation. He would report the ultimate result at the proper time. The operation had not been found difficult.

The second case proved fatal, and the specimens shown consisted of the ovaries and the uterus. In this case the operation had been found troublesome, owing to excessive thickness of the abdominal wall from the deposit of fat. This condition had also interfered with the proper closure of the wound—the peritoneal surfaces could not be brought into due apposition, and, consequently, the fatty tissue remained to a certain extent in contact with the intestines. An abscess formed and opened into the abdominal cavity, and this was the cause of death.

The President was not inclined to lay so much stress on the union of the peritoneal surfaces as was generally done.
Dr. Polk had formerly regarded it as highly desirable, but he had lately seen it questioned by Dr. Goodell, of Philadelphia.

The President added that views similar to Dr. Goodell's had been published by Mr. Knowlesy Thornton, Sir Spencer Wells, and others, but that he could only look upon them as theoretical. For his own part, he would aim at perfect union.

Tumor of the breast.—Dr. Hunter showed a small tumor that he had removed from the breast by excision. It was not connected with the gland. Probably it was a lipoma, but it had not yet been examined.

Oophorectomy.—Dr. Hunter also showed the ovaries removed in two cases of oophorectomy. In the first case, on cutting the Fallopian tube, a dark fluid spurted out, as from the umbilical cord when divided between two ligatures. This was carefully sponged out, but septic peritonitis took place and ended fatally. The ovaries showed cystic degeneration.

In the second case there was likewise cystic degeneration. The patient had done well, although at first there was a moderate peritonitis. In the first case he had derived great aid, in searching for a bleeding point, by passing a large Ferguson's speculum through the wound down to the source of the hemorrhage. Sponging through this instrument, he had been able to see the exact point from which the bleeding proceeded, and apply a Paquelin's cautery to it.

Dr. Leck asked if patients had not been known to be restored to health, after suffering with the symptoms for which Battey's operation was now done, by other than operative treatment. He referred to times preceding the introduction of the operation.

Dr. William M. Chamberlain remembered an instance in which restoration to health followed treatment in a lunatic asylum, where the opium habit was overcome.

Dr. Benjamin F. Dawson could not see how medicinal treatment could prove curative in cases where the ovaries were bound down by adhesions.

Dr. Leck called attention to the fact that, of the five cases reported at this meeting, three had proved fatal. He thought the inference was, that all possible measures should be exhausted before resorting to the operation.

Dr. Hunter and Dr. Paul F. Mundé would emphasize the distinction that ought to be drawn between organic disease of the ovary, on the one hand, and its functional derangement or its crippling by surrounding deposit, on the other hand.

Ovariotomy.—Dr. Jantzen showed two small ovarian cysts that had been removed, five days before, by Dr. Hart, of Plainfield, N. J., at the Muhlenberg Hospital in Plainfield. They were polycystic without adhesions. The patient was doing well.

Fibrous Polypus simulating Inversion of the Uterus.—Dr. Mundé showed a polypus that he had removed in a case in which difficulty had been met with in the diagnosis, owing to the tumor having contracted adhesions to the cervical canal on all sides. It was only when the patient was anesthetized and actually on the operating-table that he had been able to feel the body of the uterus, which was very small.

Pregnancy with Fibrous Tumors of the Uterus.—The President showed an unraptured four months' ovum that had been expelled spontaneously from a uterus in which the existence of two fibrous tumors had been diagnosed. Their presence had made the condition of pregnancy difficult to determine.

Dr. Leck was accustomed in such cases to rely a good deal on the mammary signs, and he attached considerable importance to the peculiar bluish tint of the vagina.

Adenoma of the Rectum.—Dr. Polk showed a patient from whose rectum he had enucleated an adenoma as large as a man-
prised to find that he had opened into a spina bifida. The child died within thirty-six hours. There was considerable fatty tissue over the sac, which was the cause of the error.

Dr. J. B. Hunter asked the President if, in the case of the monster presented, the arrest of development might not have been due to the effect of ergot or other means which the mother had probably taken to produce abortion.

The President replied that a very interesting and suggestive question had been raised, but he did not think it would be practicable to answer it with our present knowledge of fetal pathology and the effect which maternal impressions produced upon fetal development.

Ovariotomy in Old Age.—Dr. J. E. Janvins presented a monocyte removed in June last from a woman seventy-seven years of age. Except for the influence of the rapid growth of the tumor, the patient was in good health. The operation was very simple, there being no adhesions, and the tumor being removed through an incision only two inches long. She made an excellent recovery. He believed this to be the oldest patient upon whom successful ovariotomy had been performed in this country, and perhaps in the world. During the same month he operated upon two other patients, in one performing double ovariotomy, and in both recovery went on rapidly. These three patients were operated on in the extremely hot weather of that month, and yet, in spite of the enervating effect of the heat, the recovery was very quick with all of them.

Dr. P. F. McDonald thought the operation had before been performed successfully upon patients seventy-seven years of age, in this country and in Europe. He thought that in the case of old people the question would arise whether it were not better to resort to the temporary benefit from tapping rather than subject them to the risks of ovariotomy.

Dr. Hunter had a case at present in which he had advised the patient, seventy years of age, against ovariotomy, tapping having already given relief several times.

Puerperal Convulsions.—Dr. W. M. Chamberlain had recently been called in consultation, and received from the attending physician the following history: A young woman, well developed, but of the dark type, of strumous habit and often ailing, was now in the eighth month of her first pregnancy. During the earlier months she had suffered to an unusual degree from neuritis and digestive troubles. For the last two months she had been in the country, and had been much better. She had returned to town the day previous, entertained company at dinner, and retired at 11 with a very bad headache. At 3 in the morning she had got up to pass water, and while doing so had been seized with a convolution, in which she fell to the floor, bruising her face and cutting her lip badly. Convulsions had occurred several times in the day, and, when Dr. Chamberlain saw her, at 3 p.m., she was profoundly comatose. The face was swollen from bruises and livid with venous congestion. The urine, on boiling, was nearly all solid coagulum. The vagina and cervix, exposed by Sims's speculum, were even more livid than the face. The uterine neck was still columnar, and the os closed. Dilatation was begun at once with hard-rubber dilators, followed by Barnes's bags. In the first hour there were three convulsions. After the os was opened to the size of a dollar they ceased, and did not recur. Twelve hours after beginning dilatation, and twenty-four after the first convolution, delivery was accomplished with the forceps. The uterine pains had been of the feeblest kind, and manual expression had been continuously employed. The loss of blood was very moderate. The child, whose heart-beat had been unrecognized for an hour previous, was asphyxiated. Its restoration was for a time much in doubt, but was finally accomplished. The mother remained unconscious. Dr. Chamberlain advised purgation by croton-oil, a hypodermic injection of one sixth of a grain of pilocarpine, and chloroform inhalation in case the convulsions should return. The condition of the patient seemed so very unpromising that the attending physician did not execute these suggestions. He, in fact, did nothing, and six hours later reported the patient as still comatose, as having had two convulsions, and as apparently moribund, with a temperature of 106° and a pulse of 160. But from this point she began to improve. Consciousness slowly returned, and six hours later the temperature had fallen to 101°. The second day albumin disappeared from the urine, and now, after five weeks, she was quite well and nursing her baby. The case is particularly interesting as showing how Nature sometimes relieved the astringent patient. Undoubtedly a full venesection was indicated in this case, but, although considered, it was not done.

Dr. McDonald mentioned a case in which he had employed acclenchment force, using the fingers and hand in dilatation instead of instrumental dilators. The patient was the mother of several children, and was eight months advanced in pregnancy. Convulsions began in the night, and when her physician arrived, at 10 a.m., he found her comatose, in which condition she remained until Dr. McDonald saw her in the evening and effected delivery. One convolution occurred while dilating the cervix. This procedure required about fifteen minutes. The patient was then breathing sterterously, the temperature was 102°°F., the pulse 140, and she was considered moribund. Death took place half an hour after delivery. The child was born apparently dead, but was easily resuscitated, and lived a month.

Dr. E. L. Partridge had seen a good many cases of puerperal eclampsia, and had sought for a reliable sign upon which to base a favorable or an unfavorable prognosis. The number or rapidity of the convulsions did not constitute an indication. He had found that, when a rapid rise of temperature took place, a degree or two within one or two hours, until 104° F., or more, was reached, the patient usually died. While delivery should undoubtedly be produced after the occurrence of puerperal convulsions, he did not think that we could foresee their development with sufficient certainty to justify us in anticipating them by the induction of labor.

Disappearance of Uterine Tumors during Pregnancy.—Dr. Banner stated that at a former meeting of the society he had related the history of a case of successful delivery in a patient carrying a fibroid tumor in the cervix uteri. She afterward became pregnant, and he, Dr. Lee, and others diagnosed a fibroid in the cervix, and also in the posterior wall of the body of the uterus, and advised the induction of labor at the eighth month. The patient entered the Nursery and Child's Hospital, and Dr. Partridge and the house physician were unable, both before and after delivery, to discover any signs whatever of a tumor of the uterus. It would seem, therefore, that the tumors must have undergone retrograde metamorphosis or absorption during the course of pregnancy. Dr. Partridge said that several very careful examinations were made in the case, and no signs of a tumor could be found.

The President said that an amusing case of this kind occurred some years ago when he was associated with the late Dr. Eliot. A wealthy lady of Brooklyn became pregnant, and consulted Dr. Eliot, Dr. Emmet, and some other eminent New York physicians, with regard to her condition. They agreed that there existed a large fibroid tumor of the uterus. As pregnancy advanced, the patient felt less trouble from her condition, but placed herself under the care of Dr. Budd when the time for confinement approached. At that time Dr. Budd was unable to discover any tumor, and, at the request of the lady, wrote a certificate to that effect. The lady made this the basis of a
suit against the physicians, to some of whom she had previously paid large consultation fees.

Dr. Hunter had seen a case in which a fibroid tumor of the uterus, of the size of a Mandarin orange, disappeared during pregnancy, but reappeared after involution.

DEATH FROM PRECEPAL ECLAMPSIA.—Dr. Dawson related the history of a case as follows:

M. A., primigravida, aged twenty-two, finished her last menstruation January 17, 1883. Until within two hours preceding the first convulsion she complained of no unpleasant symptom except an occasional pain in the cardiac region, with slight palpitation.

On September 25th she ate a hearty dinner and retired in her usual good health, but was awakened about 1:30 a.m., September 26th, by severe pain in the abdomen, and, thinking that she was to be confined prematurely, she started at once for the New York Foundling Asylum. She had no sooner got into bed than she was seized with a convolution. This was at 3 o'clock A.M. Dr. Bledget, who was immediately summoned, reached her bedside at 3:15, when the second convolution occurred. He administered one fourth of a grain of morphine and drew off two ounces of urine, which was all the bladder contained. The urine had a specific gravity of 1.029, and, on bleeding, was found to be nearly solid with albumin.

Dr. O'Dwyer arrived at 3.45 A.M., and at 4 o'clock another quarter grain of morphine was administered, and the patient was placed in a hot wet pack, where she was kept for five hours, during which time, as well as nearly all the remainder of her life, she was kept under the influence of chloroform. Wet cups were also applied over her kidneys.

At 6 A.M. one ounce of infusion of digitals and one drachm of acetate of potash were given by the rectum, and three drops of croton-oil by the mouth, but no movement of the bowels was effected.

In spite of the chloroform and morphine, the patient had eight convulsions between 3 o'clock and 9:15 A.M., being constantly in an unconscious condition. At 9 A.M. the pack was removed, four ounces of urine, of the same character as before, were drawn, a third quarter grain of morphine was given, and attempts were made to induce labor.

A vaginal examination, made when the patient was first seen, gave no evidence of commencing labor. The cervix was long and conical, and the external os was firmly closed. By 10 A.M. dilatation had been made with the finger sufficiently to permit of the introduction of a Barnes's dilator. During the remainder of the day half a grain of morphine was administered, making in all one grain and a quarter; also four ounces of brandy, four ounces of the infusion of digitals, three drachms of the acetate of potash, and several ounces of beef extract by the rectum were given.

The inhalation of chloroform and the attempts to dilate the cervix canal by means of the Barnes's dilator were continued until about 4 P.M., September 26th. At that time, the dilators having proved ineffective, although they were so thoroughly distended that one of them burst, and the convulsions still continuing (twelve had thus far occurred), the cervix was incised and stretched and torn with the fingers until the forceps could be applied, and, at 5 P.M., a dead child was extracted by Dr. O'Dwyer. The placenta and membranes were removed intact about ten minutes later; the uterus contracted well, and hemorrhage was very slight.

At this time the patient's general condition was still fair, the pulse was 128 and tolerably strong, the temperature was 103° F., and the respirations 29.

The convulsions, however, recurred with nearly the same frequency as before delivery, in spite of the continued administration of chloroform, and from 9 A.M. until death she passed only two ounces of urine. Between the time of delivery, which occurred at 5 A.M., September 26th, and death, which took place at 2.45 A.M., September 27th, there were five convulsions, making, in all, nineteen in the twenty-four hours.

The hot wet pack was reapplied at 7 P.M., September 26th, and the patient perspired profusely for several hours, but to no purpose.

A microscopical examination of the urine, made by Dr. Northrop, showed hyaline, granular, and epithelial casts (most of them large), and free granular epithelium. There was no blood nor fat, nor fatty casts.

Dr. Dawson asked the question whether in such cases, when it was evident that the patient must otherwise die, it might not prove of benefit to withdraw the poisoned blood by venesection, replacing it at the same time by transfusion of fresh blood.

Dr. Mennö said the suggestion had been made before, but he was not aware that it had ever been acted upon. It was to be remembered that transfusion was always attended by symptoms of shock, more or less severe, and, considering the condition of the patient in these cases, the procedure would be very hazardous. Nevertheless, as, on theoretical grounds, it would seem to offer a possibility of rescuing the patient from death, he thought that he would resort to it on the next favorable opportunity.

Dr. Chamberlain had performed venesection without transfusion, apparently without effect.

The President thought that patients with puerperal convulsions were too liable to be over-treated. In his opinion, the induction of labor and narcotization during convulsions by hypodermic injections of morphia constituted all the treatment that was called for.

Dr. Chamberlain called attention to the interesting fact that, in his own cases, and in most cases, when the patient lay in the comatose state, the irritation produced by dilatation of the cervix caused convulsions, and that after dilatation was complete the convulsions usually ceased. The nausea of pregnancy and that produced by the presence of fibroids, etc., were known sometimes to disappear after dilatation of the cervix.

In the further discussion upon Dr. Dawson's case the impression prevailed that venesection and transfusion would prove of doubtful benefit.

Henry J. Garreeués, M.D.,
Benjamin F. Dawson, M.D.,
Frank P. Foster, M.D., ex-officio,
Committee on Publication.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A stated meeting was held October 27, 1888, Dr. H. B. Sands Chairman for the evening.

A PROBE FOR THE EXAMINATION OF FISTULA.—Dr. A. C. Post presented a silver probe with an ivory handle, which he had found superior to the ordinary plain probe used in the examination of fistula in ano, inasmuch as it did not turn in the fingers. In this connection Dr. Post also remarked that he frequently received patients of whom it had been said by their physicians that they had incomplete external fistula, but he had rarely failed, after careful search, to find the internal opening, which was usually situated just above the internal sphincter. The mistake was very commonly made of searching too high up for the internal opening. Doubtless most fistulae began at the mucous membrane from within, and gradually narrowed until they made an opening without. The probe could also be bent into a hook and used for the extraction of foreign bodies from the nasal and aural passages.

URETHRAL FISTULA.—Dr. Post said that a patient recently presented himself at his clinic with an abscess on the lower side of the penis, near the meatus, which was found, on incision, to communicate with the urethra; it had been preceded by gonorrhea. He asked the chairman whether, in his opinion, it was better to repair the edges of the fistula and close it by suture, or if the opening would close by withdrawing the urine regularly with a catheter, so as not to allow it to come in contact with the edges of the fistula. The Chairman replied that he had not had experience with urethral fistulae so near the meatus; he had effected a cure of those near the peno-scrotal junction by performing a plastic operation.
Wandering Testicle.—Dr. B. W. McCready had been called to see a child, between two and three years of age, suffering from colicky pains and erections. The child had been seen by a physician, who had administered a good deal of medicine, but without giving relief. On stripping the patient, who was crying with pain and having erections, a little tumor was seen in the inguinal canal, which was recognized to be a testicle. On pushing it down into the scrotum the pains ceased, but recurred, with erections, when the testicle was again drawn into the inguinal canal. Dr. McCready gave the child about two grains and a half of bromide of sodium four times a day, and the following day the pains and erections entirely ceased.

Gastro-enteritis.—Dr. Francis Delafield related the following case: In the latter part of September he was asked to see a German physician, who, it was said, was seriously ill. He found a man, apparently between forty-five and fifty years of age, in bed, unable to give any account of himself except to complain of a most severe headache. The skin was cold and clammy, the pulse very rapid and feeble, the face drawn and sunken and of a dusky color, the parts about the eyes were sunken, and the whole appearance of the man was that of a person almost in collapse. His wife said that he had been sick a week, that the attack commenced with vomiting, purging, and febrile movement. The fever lasted for twenty-four hours and then ceased; vomiting and purging had continued the entire week, the matter passed and ejected being of a watery character and in large quantity. One or two of the patient’s friends had seen him, but he had refused all medical treatment. His wife was positive that during the last four days before Dr. Delafield saw the man he had passed no urine at all; the nurse confirmed this statement. The bladder, however, seemed contracted rather than dilated. The patient absolutely refused to take medicine. Fomentations to the lumbar region were advised, and thoroughly applied during the night, and the next morning eight ounces of urine were passed. The urine was high-colored and of high specific gravity, but contained no albumin and no casts. On that day the purging ceased, also the vomiting, except when food was taken. The following day he again passed ten ounces of urine, and began to feel better in every respect; the headache ceased, the pulse became slower and fuller, the expression of the face changed, he became rational, continued to pass his urine, and at the end of a week was fairly convalescent. The case seemed to be of interest in two respects: in the first place, with regard to suppression of urine for so long a period in what appeared to be simply a case of rather severe gastro-enteritis; and, in the second place, with regard to so severe a case of cholera morbus occurring at a time when it was known that an epidemic of true cholera had already begun in Asia. It was known that, when epidemics of cholera began in one country, the disease gradually spread until it had invaded many countries, and that its advent was apt to be preceded by unusually severe cases of what was apparently ordinary cholera morbus or gastro-enteritis.

Litholapaxy.—The Chairman reported that, nine days ago, he had performed Bigelow’s operation upon a gentleman sixty-six years of age, and removed a soft, phosphatic calculus, one inch and a quarter in diameter. The patient had been treated twelve years previously by the late Dr. J. L. Thébaud, who removed, by lateral lithotomy, a uric-acid calculus, weighing upward of four ounces, and measuring, in its several diameters, three inches and a quarter, two inches and five eighths, and one inch and a half. During this operation the rectum was wounded, and ever since the patient had suffered from a recto-scrotal fistula large enough to admit the tip of the index-finger, which could readily be passed from the rectum into the membranous division of the urethra. This fistula had not seriously affected the patient’s health, but had caused considerable annoyance. The urine voided through the penis was often more or less feculent, and much of the urine passed into the rectum, so that the patient was compelled to assume the sitting posture during micturition, as usually this act was simultaneous with that of defecation. Another singular symptom resulted apparently from the fistulous communication; namely, the habitual passage of soft feces, in the form of narrow cylinders, having a diameter varying from a quarter to half an inch. This symptom had been thought to denote a stricture of the intestine; but no other evidence could be obtained to corroborate such a view, and a digital exploration of the rectum had a negative result. On introducing the finger into the rectum, however, the sphincter muscle was discovered to be unusually strong and active; and it seemed probable that the small diameter of the feces when voided was due partly to a reduction in their consistency from admixture with the urine, and partly to their passage through a highly contractual orifice. The absence of stricture was further indicated by the fact that the symptom described had existed from the time when recovery took place after lithotomy.

The operation of litholapaxy presented only one peculiarity. To prevent the lithotrite, while introducing the instrument, from entering the rectum, it was found necessary to guide its point by means of the forefinger passed into the rectum and through the fistula. No unfavorable symptoms had followed the operation, and the patient was already convalescent, but Dr. W. M. Polk alluded to the fact that in certain cases long, cylinder-like feces were passed in the absence of stricture, the cause being said to be a kind of spasm of the sphincter ani.

Dr. Post asked if the edges of the fistula could not have been repaired and closed with sutures.

The Chairman replied that the patient’s age and condition would hardly justify the operation.

AMERICAN PUBLIC HEALTH ASSOCIATION.

The eleventh annual meeting was held in Detroit, November 13, 14, and 15, 1883.

First Day.

The meeting was called to order by the President, Dr. Ezra M. Hunt, of New Jersey, at 10 A.M. After prayer by the Rev. Dr. Bishop Harris, and various announcements by the chairman of the local Committee of Arrangements, Dr. William Brodie, the treasurer, read his annual report. The total receipts during the year were $4,257.23, and the disbursements $2,928.93, leaving a balance of $1,328.30 in the treasury.

The first paper was by Dr. D. E. Salmon, of the Agricultural Department, Washington, on the Texas Cattle Fever. The paper was a very elaborate one, and sketched the history, etiology, and symptoms of the disease very fully. The author controverted the opinion expressed in papers previously read by Dr. Joseph R. Smith, of the army, before the association, that no specific disease existed which could properly be termed “Texas Cattle Fever.” Dr. Salmon held the view that the disease described under this name was a distinct, specific disease, contagious in its nature, and very fatal. He advocated laws to prevent the spread of the disease. The paper was briefly discussed by Dr. J. H. Ratch, of Illinois, and Dr. Hilary Ryan, of Texas.

Dr. J. M. Partridge read a paper on Swine Plague, an infectious disease attacking hogs. It was estimated that the annual loss to the country from the disease amounted to $15,000,000. He referred to the investigations of Dr. Detmers, who had discovered a bacillus in the tissues and fluids of the affected animals. This organism was believed to be the cause of the dis-
case. It might be introduced in the food or drink, or inoculated upon abraded or wounded surfaces. Carbolic acid, in the dose of ten drops to each one hundred pounds of weight of the animal, was believed to prevent the disease. It should be given three times a day. The sick animals should be promptly isolated or killed, and the infected localities disinfected. The healthy animals should be separated into small herds.

A paper by Dr. W. T. Belefield, of Chicago, on *Actinomyces*, which had recently been observed among the cattle at the stock-yards in that city, was read and discussed by Professor James Lown, of Ithaca, N. Y.

Dr. George M. Sternberg, of the army, read an elaborate paper on *The Etiology of Malarial Disease*. The paper was accompanied by statistical tables, compiled from the records of the Surgeon-General’s Office, showing the prevalence of malarial diseases at various military posts in the United States. No very definite conclusions were reached, except that heat, moisture, and vegetable decomposition were necessary for the production of the specific cause of malarial fever.

A paper upon *The Etiological Association of Organic Matter with Malaria*, by Dr. A. A. Woodhull, of the army, was read by Medical Director A. L. Gibson, of the navy. It was an exhaustive presentation of the various theories of the causation of malaria, without offering any new views. The New Lenox trial of last year was extensively referred to, and the evidence for the defense mildly criticised.

Dr. Charles Smart, of the army, read a paper on the same subject, in which the etiological importance of polluted water was strongly supported. Dr. Smart cited numerous instances from literature, and referred to observations and experiments of his own, which seemed to show that the importance of water infected with the malarial poison as a cause of the disease deserved more attention than it had hitherto received.

At the evening session, addresses were made by Governor Beggole, of Michigan, Dr. William Brodie, of Detroit, and Dr. John Avery, President of the State Board of Health. The president of the association, Dr. Hunt, then delivered *The Annual Address*, which recounted in happy phrases and eloquent periods the history of the association, the advancement of sanitary science, and the bright promises of the future. The address occupied over an hour in its delivery, and was warmly applauded by the large audience present.

Second Day.

The following papers were read: *On Changes in Types of Malarial Fever in Sumter County, Ala., from 1883 to 1883*, by Dr. R. D. Webber, of Livingston, Ala.; *Interrogatories on Malarial Fever*, by Dr. J. W. Penn, of Humboldt, Tenn.; and *The Clinical Thermometer in the Prevention of Malarial Disease*, by Dr. T. F. Wood, of Wilmington, N. C.

They were briefly discussed by Colonel G. E. Warin, Jr., Dr. A. M. Bell, Dr. G. Devon, Dr. O. W. Wright, Dr. G. E. Ransney, Dr. Oldright, Dr. Trescott, Dr. G. H. Roudé, Dr. F. Formento, Dr. E. L. Griffin, Dr. V. C. Vaughan, Dr. P. H. Bryce, and Dr. Sternberg. The relations of the ground-air and the movements of the ground-water to the production of malarial diseases was more particularly pointed out by Dr. Roudé, Colonel Waring, Dr. Wight, and Dr. Bryce.

Dr. W. K. Newton, of Paterson, N. J., read a long paper on *The Sanitary Control of the Food Supply*, which was followed by a paper on the same subject by Professor A. R. Loomis, of New Jersey, read by Professor Kodzie, of Michigan. The subject was further discussed by Dr. Vaughan and Dr. Wilson. More and better laws, stricter enforcement of the same, and the education of a larger number of men and women capable of making analyses of food, were recommended as the most promising remedies to restrict the adulteration of the supply of food.

Dr. A. L. Gibson, of the navy, read a paper on *Vital Statistics as Sanitary Monitors*. Dr. Gibson advocated a more rational system of vital statistics than that usually carried out in this country. The relation of the number of sick to the population, the duration of sickness, and the relation of deaths to the sick, were the elements of real value in a report of vital statistics. The mere tabulation of births, marriages, and deaths was of very little assistance, even with the aid of the refinements of the higher mathematics, in arriving at reliable conclusions.

Dr. R. B. S. Hardin, of Pensacola, Fla., sent a paper on *Yellow Fever at Pensacola in 1882*, of which an abstract was read by Dr. Devoty.

Dr. C. J. Lundy, of Detroit, read an admirable paper on *School Hygiene*. He referred to the tendency to burden the pupil with too many studies, long hours of study, over-heating, bad lighting, and imperfect ventilation of school-houses, unsuitable desks and seats, and the neglect of bodily training. He dwelt upon the great increase in nearsightedness, and urged greater attention to the sanitary necessities of school-children. The paper was discussed by Dr. A. N. Bell, Dr. E. J. Jones, Dr. J. F. Nootes, and Dr. L. D. Wilson.

At the evening session, addresses were made upon *The Importance of Physical Training*, by Professor J. Madison Watson, of Elizabeth, N. J., and Professor D. A. Sargent, of Cambridge, Mass., and upon *The Eminent Domain of Sanitary Science and the Usefulness of State Boards of Health in Guarding the Public Welfare*, by Dr. James E. Reeves, Secretary of the State Board of Health of West Virginia. Dr. Reeves’ address was well received, and elicited much favorable comment. [It was published in full in our issue of November 17th.]

Third Day.

The Advisory Council presented a resolution requesting Congress to re-enact the law of June 2, 1879, to prevent the introduction of contagious diseases into the United States. Also a resolution asking Congress to appropriate a suitable sum annually to be expended under the direction of the National Board of Health in making experimental researches in sanitary science. Also, a resolution commending the services of Surgeon-General Wales in the establishment of the National Museum of Hygiene. Also, a resolution recommending a fire-proof building for the Surgeon-General’s library, and asking that Congress make a suitable annual appropriation for keeping these valuable institutions in their present efficient condition, and depreciating their separation. The resolutions were adopted.

The Report of the Committee on Compulsory Vaccination was read by Dr. S. W. Abbott, of Wakefield, Mass. It was recommended that vaccination be made compulsory.

The Removal of Decomposable Materials from Households was considered in an elaborate paper by Mr. E. Hegwood, C. E., of New York, which was read by Professor Kodzie, Dr. Oldright, of Canada, read an exceedingly practical paper on *The Overhead Ventilation of Sewers*. The Sanitary Care of Households was the title of a paper by Dr. J. H. Raymond, of Brooklyn, read by Dr. A. N. Bell. These papers were discussed by Colonel Waring, Dr. Bell, Dr. Oldright, Colonel D. P. Haddon, of Memphis, Dr. Wright, Dr. Brodie, Dr. Sheehan, Dr. Gibson, and Dr. Azel Ames. Colonel Haddon stated that the Waring system of sewerage as introduced in the city of Memphis was a complete success, and demanded the attention of all sanitary authorities.

Abstracts of papers on Typhus Fever in New York, by Dr. E. H. James, "Baltimore Catacombs," by Dr. John Morris, and Pullman from a Sanitary Point of View, by Dr. O. C. De
Wolf, were read by Dr. C. W. Chamberlain, Dr. Rolé, and Mr. J. K. Allen, of Chicago. Dr. J. N. McCormack made a few practical remarks on The Resolution of Small-pox, after which a number of papers were read by title and ordered printed in the "Transactions" of the association.

At the evening session, the Rt. Rev. Hugh Miller Thompson, Bishop of Mississippi, delivered an eloquent address on Sane Humanity, after which Dr. Foster Pratt, of Michigan, read a statistical paper on The Increase of Insanity in the United States. Dr. Pratt's paper was very elaborate, and elicited a lively discussion, resulting in the adoption of a resolution requesting Congress to enact laws to prevent the introduction of paupers, criminals, and insane persons from foreign countries.

After a vote of thanks to the local Committee of Arrangements, and others who had contributed to make the meetings so pleasant and successful, the association adjourned, to meet in St. Louis on the third Tuesday in October, 1884.

The following-named gentlemen were elected officers for the ensuing year:

President, Dr. A. L. Gibson, of the navy; First Vice-President, Dr. James E. Reeves, of West Virginia; Second Vice-President, the Hon. Erastus Brooks, of New York; Secretary, Dr. Irving A. Watson, of New Hampshire; Treasurer, Dr. J. Breese Lindsley, of Tennessee; Executive Committee, Dr. T. L. Neal, of Ohio, Dr. J. D. Gatch, of Indiana, Dr. H. P. Walcott, of Massachusetts, Dr. G. Detrov, of Louisiana, Dr. Charles Smart, of the army, Dr. D. Fraser, of South Carolina.

---

Reports on the Progress of Medicine.

OTOLONY.

By CHARLES STEMDIAN BULL, M.D.,

LECTURER ON OPHTHALMOLOGY AND OTOLONY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO THE NURSERY AND CHILD'S HOSPITAL.

Calcium Sulphide in Aural Diseases.—Bacon ("Arch. of Otology," xii, 2) has used the calcium sulphide in many cases of acute otitis media with great advantage. In several cases, where the membrana tympani was highly congested and bulging, all the inflammation subsided under the use of this remedy, and he believes that it will prevent the formation of many cases if given sufficiently early in the course of the disease. Its most decided action seems to be in those cases of otitis media in which the discharge has already commenced, as well as in cases of furuncles in the external auditory canal, where it will either arrest the inflammation and cause the boil to dry up, or it will promote suppuration and cut short the disease. The pain so frequent in these diseases, even when the peristeam is involved, is often relieved at once. In diffuse inflammation of the external auditory canal, and in mastoid disease, whether affecting the pneumatic cells or the peristeam and tissues externally, greater benefit, according to Bacon, will be obtained from its use.

The Production of Artificial Deafness, and its Bearing on the Etymology and Evolution of Ear Diseases.—Cassells (ibid.) gives the results of his observations upon this subject, dating back to 1876, and formulates the following propositions:

1. A certain degree of tympanic tension is essential to perfect hearing.
2. The essential cause of all the affections of the organ of hearing is a disturbance of the normal tympanic tension.
3. All the pathological phenomena of the diseases of the ear evolve themselves with regular sequence. The measure of the normal tympanic tension may be regarded as the difference between the air-pressure, at any level, upon the outside of the membrana tympani of a healthy ear, plus the traction force of the accommodating apparatus of the organ, on the one hand, and, on the other, the opposing air-pressure within the tympanum plus the resistance of the tissues. In considering the first and second propositions, Cassells found it necessary to prove that a disturbance in the tympanic tension could cause tissue-change in the structures of a healthy ear. To accomplish this he undertook some experiments in the production of artificial deafness on a man, aged forty-three, in a room at the temperature of 64° Fahr., in clear, dry weather. Two methods were used to disturb the balance of the tympanic tension. One, the Valsalvian method, was employed to increase the density of the air contained in the tympanic cavity. The other, known as Mais­sia's experiment, was used for the purpose of rarefying the air in that cavity. The Valsalvian experiment gave no positive results, and the Mais­sia's method was then resorted to. A manometer was hermetically fixed in the outer orifice of the external meatus of the right ear. The act of swallowing was then performed by the patient in a deliberate manner, several times in succession, water being used to facilitate this process, during the performance of which the nostrils were open. No movement took place in the mercenial column of the manometer during this stage. The act of swallowing was then repeated as before, but with closed nostrils, and at the first act of deglutition the column of mercury in the manometer descended considerably. On this act being repeated a second time, it descended still farther, and, during its third repetition, the mercury was drawn altogether into the meatus. The first act of swallowing caused the membrana tympani to vibrate backward and forward several times, and then to recede a little, becoming at last visibly more concave, and accompanying this an immediate dullness in the general hearing. On a repetition of this act, the membrane became still more concave, and signs of congestion began to appear on its surface, along the anterior aspect of the handle of the malleus, and the patient experienced a general and deeper muffling of all sounds and a slight tinnitus. With the third act of swallowing with closed nostrils, the membrane was rigidly fixed, the congestion of its tissues rapidly increased, there was a complete muffling of all natural sounds; but the tic-tac of the watch was heard ringing out clearly and distinctly at an increased distance. The perception of aerial tones of the diapason, ranging from C to D = 512 to C = 1,024, held close to the ear, was almost completely extinguished; the perception of transmitted tones was slightly diminished. On the patient releasing his nostrils and swallowing a few times in succession, the membrane soon regained its normal position, and in an hour or so after­ward the hyperemia of its surface had diminished; the dullness of hearing lasted for some time afterward. The next stage of experimentation consisted in hermetically sealing up the orifice of one meatus, the other being left open. Mais­sia's experiment was then again performed, and, after the act of deglutition had been performed three times in succession, all the previous sensations and appearances were experienced and seen on the membrane of the left and open ear, while in the right and closed ear no such sensations were felt. The moment, however, that the plug was removed from the meatus of the hitherto closed ear, similar sensations to those which had been felt in the left ear now made themselves known at once in the right ear, showing that the air in the cavity of the tympanum had been exhausted, and that the membrana tympani had been pressed in by the superabundant outside air-pressure. This conclusion Cassells tested in the following way: A pneumatic speculum was in­serted into the orifice of the right meatus, that canal being hermetically closed by the instrument. The last stage of the ex-
periment was then repeated in all its details, and the membrana tympani inspected while these were being carried out. Searingly any motion was to be seen in the membrane of the closed ear, and none of the subjective symptoms were called forth so long as the canal remained closed. On the left ear all the former symptoms were as prominent as ever. Air was now admitted to the canal of the lithographed closed ear, and the behavior of the membrana tympani watched. It was seen to be drawn in suddenly with a bang toward the tympanum and to remain in that position, its surface being very concave. All the former sensations and appearances were now felt in the ear and seen in the membrana tympani.

**Galvanic Irritation of the Acoustic Nerve.**—Kieselbach ("Arch. f. die ges. Phys.," xxxi, 7, 8) considers the origin and perception of vascular murmurs in general. 1. Vascular murmurs in the ear may occur as soon as the exit of the sound-waves is hindered (closure of the external auditory canal, etc.). 2. As soon as the murmur itself becomes abnormally loud (through increased supply of blood, roughness or bends in the walls of the blood-vessels). 3. When the irritability of the terminal filaments of the acoustic nerve is on the increase, or when there is a pathological hyperesthesia of the same filaments. On the other hand, the vascular murmurs may be diminished by restoration of the normal exit for the sound-waves, or by diminution of the irritability of the terminal filaments of the acoustic nerve.

**Pyemic Attacks and Acute Purulent Inflammation of the Tympanum.**—Moos ("Arch. of Otolaryng." xii, 2) thinks that when attacks of pyemia occur in the course of a chronic suppuration of the ear, we can judge more correctly of the history of the disease than when they occur in acute cases. In the first place, we are justified in assuming a diseased condition of the petrous bone, especially a gradually progressive caries, which favors the propagation of the disease to one of the sinuses of the brain. It is quite otherwise when these attacks occur during the acute stage of inflammation. If the case is not one of acute caries, associated with purulent inflammation of the tympanum, or if the presence and malign influence of microorganisms in the inflamed parts can be excluded, the following theories of the condition must be considered: 1. Intermittent fever. This diagnosis could not be accepted in the case reported, for it is well known that the occurrence of new chills and increase of temperature contra-indicate the presence of intermittent fever. 2. Phlebitis and thrombosis of one of the veins or sinuses near the tympanum. This would scarcely be possible during the course of an acute affection of the middle ear, without the presence of certain abnormalities in the structure of the organ which would favor a rapid extension of the inflammation to the neighboring veins. Opposed to the theory of phlebitis and thrombosis of a large vein or sinus, there were in the case reported no observable metastatic centers of inflammation, such as are generally caused by the breaking down of a large thrombus. Upon the theory of a phlebitis and thrombosis of a small sinus—for instance, the superior petrosal—the non-discovery of embolisms in the parenchymatous organs is more easily understood. The course of the fever, also, and the variations of temperature contra-indicate an inflammation of a large sinus.

**Edema as a Symptom of Phlebitis and Thrombosis of the Lateral Sinus.**—Moos (ibid.) regards this localized edema as a symptom of rare occurrence, because the anatomical conditions on which it depends are peculiarities of development of an exceptional nature. He reports a case in a lady, aged thirty-three, with a chronic purulent discharge from the ear, which he followed up to her death. The symptoms pointed either to 1, abscess of the brain; 2, edema of the brain; 3, meningitis; 4, thrombosis and phlebitis of the lateral sinus. In regard to abscess of the brain, as two days before there were no brain symptoms, its acute stage, being short, must have been worked by very violent symptoms, but such was not the case. The high temperature argues against this diagnosis. Edema of the brain was excluded by the persistent epileptic pulse, and by the decided dilatation of the pupil on the affected side during the last hours of life. In view of these symptoms, and notwithstanding the absence of vomiting, Moos inclined to the diagnosis of meningitis, complicated by a phlebitis and thrombosis of the lateral sinus. The absence of chills was explained by the probable fact that the thrombosis had not yet broken down. The appearance of the edema in the temporal and zygomatic regions assumes the existence of a pyo-symphalous sinus, and its communication on the one side with the sinus transversus, and on the other with the deep temporal vein, after passing through the temporal bone. These conditions, however, but seldom exist, and therefore edema of the temporal region, as a symptom of thrombosis of the lateral sinus, will be of rare occurrence. Its diagnostic value, however, is as great as is that edema over the mastoid process which appears after the extension of the thrombosis in the emissarium, which runs outward through the sigmoid fossa.

**The Effects of Noise upon Diseased and Healthy Ears.**—Roosa (ibid.) believes that there is a large class of people suffering in quiet places from impairment of hearing who hear very acutely and with comfort amid a great din or noise. The disease causing the impairment of hearing thus relieved is situated in the middle ear. It is usually observed in the chronic, non-suppurative form of disease of the middle ear, but it may also be found in acute or subacute catarh of this part, as well as in a chronic suppurative process with loss of the whole or a part of the membrana tympani. The proximate cause of this phenomenon is not as yet positively known. It is probably to be found in some change in the action of the articulations of the ossicular auditus. The hearing-power of persons working in such a din as that of a boiler-shop invariably becomes impaired. The lesion caused by this occupation is one of the labyrinth, or of the trunk of the acoustic nerve. Persons thus affected do not hear better in a noise. Their hearing-power is better in a quiet place, and becomes better after prolonged absence from the exciting cause of their impaired hearing. In diseases of the labyrinth or acoustic nerve, the tuning-fork "C" is heard louder and longer through the air than through the bones of the head.

**The Morphology of the Tensor Tympani Muscle.**—Zuckerkandl ("Arch. f. Ohrenheilk.," xx, 2) has been making some investigations into the nature and mode of action of the tensor tympani muscle, with the following results: 1. The larger external portion of the muscular fibers passes into the tendon of the muscle, and hence tration of this portion of the muscle is always followed by a movement of the malleus. 2. A smaller, internal portion of the muscle, varying in thickness, does not pass into the tendon, but is inserted into the processus cochlearis on the external surface of the petrous bone. 3. The tendon of the tensor tympani muscle is connected with a band, which runs from the processus cochlearis to that point of the malleus in which the tendon itself is also inserted. To this band Magnus has given the name of "intervening band." 4. Some of the bundles of fibers of the tendon of the tensor tympani itself are so intimately united with the processus cochlearis that, even when the entire belly of the muscle is cut away, they remain behind with the intervening band as a stiff ligament. The tensor tympani in man is differently constructed from that of animals. The thick, fatty fat-nucleus in the fibers is absent. In animals these fatty bodies are constant occurrences, and are not the result of domestication. Its presence is not necessary to the
proper functional action of the muscle, for often the muscle contains connective tissue in place of the fatty bodies. This is not a fatty degeneration, the result of diminished activity, for in the almost inert muscles of the articule of man there is not a trace of fatty degeneration to be found. It is possible that originally there were more muscular fibers in the tensor tympani than were necessary for the performance of the functions of the organ, and that the fatty deposit is the degenerated portion of a too luxuriant development of muscular fibers in the cavity of the middle ear.

New Inventions, etc.

IMPROVED NASAL AND AURAL INSTRUMENTS.

By Gorham Bacon, M. D.,
Aural Surgeon to the New York Eye and Ear Infirmary.

The first wood-cut represents Duyan’s nasal speculum as modified by M. Collin, of Paris. The instrument consists of two blades, one of which is fenestrated, and, after introduction into the nostril, is easily retained in position by adjusting the screw.

![Fig. 1](image1)

Messrs. Reynolds & Co. have made this speculum for me exactly similar to one brought from Paris.

![Fig. 2](image2)

The second wood-cut shows Siegle’s pneumatic otoscope, with the following modification: In place of the hard rubber, round speculum, like Politzer’s or While’s, I have substituted a metallic speculum with the inner surface of the upper portion blackened. It is very similar to the Gruber speculum, with the exception that the upper end is made round and adjustable to the air-chamber of the otoscope. There are three sizes of these specula.

The advantages of this instrument are that the speculum is better adapted to the shape of the canal and more readily introduced. A much better view is obtained of the movements of the membranes tympani during condensation and rarefaction of the air.

Miscellany.

A LEECH IN THE LARYNX.—It seems remarkable that a leech should establish itself at the base of the epiglottis, and be perch upon the arytenoidal cartilage, without a warning note to arouse the unwilling host. We infer, however, that in the instance recently observed by M. Vieuve, such lack of knowledge on the part of the sufferer must have been the case from reading that the laryngoscope was employed to make clear what was the cause of incessant larynodynia, dysphagia, and dyspnea in the case recorded. The mirror revealed the blood-sucker in the situation already indicated. It is satisfactory to know that the patient was relieved of his symptoms and of the leech by means of a pair of Cousco’s forceps.—Lancet.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from November 17, 1882, to November 24, 1883.—Moore, John, Lieutenant-Colonel. Relieved from duty as Medical Director Department of the Columbia. G. O. 29, Department of the Columbia, November 8, 1883. —Bache, Dallas, Major and Surgeon. Assigned to duty at Fort Adams, R. I. Par. 5, S. O. 215, Department of the East, November 19, 1883. —Brooke, James, Major and Surgeon. Relieved from duty at Angel Island, Cal., and assigned to duty as Post Surgeon, Presidio of San Francisco, Cal. Par. 1, S. O. 162, Department of California, November 14, 1883. —Horton, Samuel M., Major and Surgeon. Leave of absence granted October 29, 1883, extended three months. Par. 7, S. O. 266, A. O. G., November 20, 1883. —Town, F. L., Major and Surgeon. Until further orders, to perform the duties of Medical Director Department of the Columbia. G. O. 29, Department of the Columbia, November 8, 1883. —Williams, John W., Major and Surgeon. Granted leave of absence for one month on surgeon’s certificate of disability, with permission to leave the limits of the department. Par. 5, S. O. 157, Department of the Columbia, November 12, 1883. —Appel, D. M., Captain and Assistant Surgeon. Granted two months’ leave of absence. S. O. 68, Division of the Atlantic, November 16, 1883. —Munn, Curtis E., Captain and Assistant Surgeon. Assigned to duty at Fort Warren, Mass. Par. 4, S. O. 216, Department of the East, November 20, 1883. —Winke, Charles K., Captain and Assistant Surgeon. Relieved from duty at Fort Winfield Scott, Cal., and assigned to duty as Post Surgeon, Angel Island, Cal. Par. 1, S. O. 162, Department of California, November 14, 1883. —Appel, A. H., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Warren, Mass., and assigned to duty at Madison Barracks, N. Y. Par. 4, S. O. 217, Department of the East, November 21, 1883. —Courran, J. J., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Bayard, N. M. Par. 5, S. O. 226, Department of the Missouri, November 15, 1883. —Richard, Charles, First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Adams, R. I. Par. 3, S. O. 216, Department of the East, November 29, 1883. —Wilson, George F., First Lieutenant and Assistant Surgeon. To report in person to Lieutenant Schawata, Third Cavalry, aide-de-camp, for temporary duty in connection with the completion of report of recent expedition to Alaska. Par. 3, S. O. 156, Department of the Columbia, November 9, 1883.

NAVY INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending November 24, 1883.—Medical Inspector Stephen D. Kennedy, dismissed the service by sentence of a general court-martial.

Society Meetings for the Coming Week.—Monday, December 3d: New York Academy of Sciences (Section in Biology); Brooklyn Anatomical and Surgical Society (private); Medico-Chirurgical Society of German Physicians (annual); Morrisania Medical Society (private); Utica (N. Y.) Medical Library Association. Tuesday, December 4th: New York Neurological Society; New York Obstetrical Society (private); Buffalo Medical Association; Elmira (N. Y.) Academy of Medicine; Oglethorpe (N. Y.) Medical Association; Medical Societies of the Counties of Herkimer and Saratoga, N. Y., and Hudson, N. J. Lectures and Addresses.

LECTURES ON
DISEASES OF THE KIDNEYS,
DELIVERED AT THE COLLEGE OF PHYSICIANS AND
SURGEONS.

By FRANCIS DELAFIELD, M.D.,
PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE.

Lecture V.
Chronic Parenchymatous Nephritis.—Acute Diffuse Nephritis.

Gentlemen: The next form of kidney disease we come to is chronic parenchymatous nephritis. In this disease we have essentially the same lesion as in acute parenchymatous nephritis—that is, the morbid changes are confined to the epithelium of the tubes and the epithelial cells of the Malpighian bodies. The blood-vessels and the stroma of the kidneys and the capillary vessels are unchanged. In these cases the kidney is apt to be increased in size, and sometimes very considerably. The capsules are non-adherent, and, when pulled off, the denuded surface remains smooth. The cortical portion of the kidney is thicker than natural, and its color is changed. It is whiter than usual, the pyramids are of natural size or else a little swollen, they are usually quite red, and this contrasts with the white appearance of the cortex. When we examine the kidney more minutely we find well-marked changes in the epithelium of the tubes, and in the epithelial cells lining the Malpighian bodies and the cells covering the tufts of capillary vessels contained in the Malpighian capsules. These changes are especially marked in the convoluted tubes, but are also found in the straight tubes. We also find cast matter, and occasionally a little blood in the kidney tubules.

Some of these cases, and especially those that follow upon an attack of acute parenchymatous nephritis, occur idiopathically, but others occur as a secondary or complicating condition, and sometimes begin as a chronic disease. Where the lesion follows an acute inflammation, this, instead of terminating in recovery with the return of the kidney to its natural condition, continues to advance, and the changes go on for months and years. But in other cases the lesion develops as an idiopathic chronic lesion from the first.

Chronic parenchymatous nephritis is not a very common kidney lesion, and it is perhaps the least frequently seen of any of the four different varieties of Bright's disease.

When the disease does occur, the urine generally shows changes. The quantity is usually very irregular—that is, sometimes for days and weeks in succession the patients will pass too much urine, and then, at other times, they will pass too little. There may be eighty or ninety ounces passed at one time within the twenty-four hours, and at another time it may be diminished to three or four ounces in the twenty-four hours in the same patient. The specific gravity of the urine is not usually very much changed; sometimes it is normal and sometimes a little below or a little above the normal. There is nothing characteristic in the specific gravity. Albumin is usually present in very large amount, and there may be from 50 to 70 per cent. of it in the urine almost every day. But there are a few cases in which the albumin will be present in much smaller amount, and there will only be from 5 to 10 per cent. present every day. And then there are still other cases in which it will be absent altogether for a number of days, and then it will return again. Casts can usually be found in the urine, most frequently hyaline and granular casts, but occasionally epithelial casts, and especially in cases where the disease undergoes an acute exacerbation. For, although this disease runs a chronic course, it is liable to undergo acute exacerbations, and then the epithelial casts will appear, and there may also be blood present in the urine.

In most cases dropy is present, and it is usually well marked, but it varies in amount during the course of the disease, and it comes and goes. It may diminish and nearly disappear for a while and then come back again, and so it may go on, and in the course of the months and years during which the disease lasts the dropy may come and go a great number of times.

These patients also lose their appetites, and are troubled with nausea and vomiting; and they may have uræmic attacks, during which they present the ordinary symptoms of headache, twitchings of the voluntary muscles, general convulsions, stupor, coma, spasmodic dyspnea, and persistent and repeated attacks of vomiting. When these uræmic attacks come on there is usually at the same time a diminution in the amount of urine—it may be scanty or entirely suppressed.

Quite frequently these patients suffer from a chronic bronchitis as a complicating condition, and this gives rise to a cough with a mucous or mucous-purulent expectoration. The course of the disease is usually quite slow; it may be for months, or it may last for years.

In some of these cases we may have—accompanying the changes in the urine and the changes in the blood, which give rise to the nausea—a loss of appetite and a loss of muscular strength and of mental energy, and these may be the principal symptoms throughout the course of the disease; there may be little else, unless the disease goes on and becomes worse, then at length other symptoms will be added. In other cases the dropy is developed early, and is the most marked symptom throughout the course of the disease. Some patients retain a fair appetite, their mental condition remains good, they manifest a fair amount of bodily activity, and they do not appear to be suffering from anything except the dropy. In these cases the dropy, after appearing and increasing to a certain degree, may then disappear, remain absent for weeks and months, and then at last come on again. In other cases the attacks of cerebral symptoms may come on very frequently and form a more prominent feature of the disease. In many cases there will be intervals when all the symptoms will disappear for a time and the patient is apparently
perfectly well, except that the urine does not return to its natural condition, and then, after a while, the other symptoms will come back again and be present the whole time.

So these patients go on for a long time, some of them ultimately recover, the symptoms all disappear and do not come back again, after a time the urine too returns to its natural condition, the kidneys also apparently are restored to their original state, and so the patients get permanently well. But more frequently we do not get such a favorable result, but the patients, after going on for several years, then gradually get worse and worse, the dropsy becomes persistent and does not go away again, permanent changes take place in the general nutrition and the condition of the blood, and they finally die, either in a state of extreme dropsy or in a uremic attack.

The prognosis in these cases is not good, but still it is not altogether bad. It is possible for a patient to recover even after this condition of the kidneys has lasted for several years.

The treatment of these cases resolves itself for the most part into a treatment of symptoms, and an endeavor to put the general health in the best possible condition to enable the patients to go on living comfortably while the kidney disease is running its course. We try to get rid of the dropsy by the ordinary means: by the use of diuretics, cathartics, sweatings, and the administration of drugs that increase the force of the heart's action, so that it can send a larger amount of blood to the kidneys. The loss of general nutrition and the anemia are treated by providing the patients with food that can be easily digested, and with such drugs as will diminish the gastric and intestinal symptoms; and, for the condition of the blood, iron and oxygeu may be used. The cerebral attacks are to be treated again like the dropsy: by the employment of cathartics, diuretics, sweatings, and drugs that increase the force of the heart's action and so send a larger amount of blood to the kidneys, and also such as relax the capillaries; and, in addition to these measures, opium may be given in sufficient quantities to induce sleep and quiet the restlessness. Still more than this you can do for those patients in whom it is possible to regulate their manner of living. You should send such patients to spend the cold winter season in a warmer climate, and tell them to travel about a good deal, and in this way you can try to brace up their general health, and so improve the renal condition also.

The next lesion of the kidneys we come to is acute diffuse nephritis. When a patient dies of this disease, at the autopsy we find that the kidneys are regularly increased in size, and usually this increase in size is very considerable, so that the two kidneys together will weigh from sixteen to twenty, or even twenty-four ounces. The capsules of the kidneys are non-adherent, and the surface feels smooth and regular after stripping off the capsules. When we cut open the kidney we find in some cases that there is a general congestion of the whole organ, and it appears everywhere of a uniform red color, and this congestion involves not only the kidney tissue itself, but also the mucous membrane of the pelvis of the kidney, and, besides, there may also be extravasations of minute quantities of blood into the kidney tissue. In other cases the kidney, instead of showing a general congestion, will have its cortical portion of a uniform white color, or it may be mottled by little red spots, due to minute extravasations of blood. In all cases the cortical portion is thicker than it should be, and this accounts for the increased size of the kidney. The tissue of the kidney is also more succulent and moist than it should be, and, when we cut it open, serum and blood exude; and, when we take a portion of it between our fingers and move them about, it feels more succulent than natural, and as if infiltrated with an unusual amount of serum. When we examine the kidneys more minutely, we find, in the first place, that there are marked changes in the epithelium of the tubules, and these changes are not confined to the cortex, but they also extend to the tubules of the pyramids. In a large part of all the tubules the epithelium is swollen, granular, broken down, and degenerated, it is disintegrated and detached from the walls of the tubes, and there is also a considerable amount of cast matter in the cavity of the tubes, and sometimes there is blood also. But the basement membrane of the tubules is not altered, except that the whole tube may be increased in size by reason of the distension from the detached epithelium and the cast matter in it. When we come to look at the Malpighian bodies, we find that they are increased in size, and there is a very marked growth of cells within their capsules; they are large, flat, nucleated cells, resembling those which normally line these capsules. These cells may be present in such large numbers as to compress and push to one side the vessels in the tufts of the Malpighian capsules. When we look at the stroma of the kidney, we find that it is infiltrated with serum and a moderate number of pus corpuscles, and at the same time the connective-tissue corpuscles which belong naturally to the stroma are swollen. Such an infiltration of the stroma with serum, pus corpuscles, and connective-tissue corpuscles, is found both in the cortical and in the pyramidal portion of the kidney. The production of pus corpuscles, however, is never carried to such an extent as to cause the formation of real abscesses, but there is simply a diffuse infiltration of the stroma, with only a moderate number of pus corpuscles. These, then, are the lesions of the kidney that we get in acute diffuse nephritis, and you will observe that they are more decided and extensive than in cases of acute parenchymatous nephritis.

As regards the causes of acute diffuse nephritis, we find that in a considerable number of cases we shall have a distinct history of exposure to cold and wet, but in other cases there will be no such history, and we shall be unable to discover any direct cause. With scarlet fever we find that acute diffuse nephritis is a tolerably common complication, and, moreover, I have lately found that, in some cases of acute pulmonary phthisis, acute diffuse nephritis also exists as a complicating lesion.

As regards the idiopathic cases of acute diffuse nephritis occurring after exposure to cold or wet, or from some unknown cause, where there is no scarlet fever or other primary disease, we find that they all group themselves easily into two sets of cases, according to the character of
the symptoms in each. The changes in the kidneys are apparently the same in both sets, but the symptoms in each are different. In the first place, we find a group of cases characterized by an acute invasion of the disease. Thus, a person feeling in ordinary good health will suddenly be attacked by rigors, and this will be followed by a febrile movement, in the same way as we are apt to have ushered in an attack of pneumonia, or acute tonsilitis, or some other acute inflammation of a viscus. After a short time the patient also begins to suffer from frequent micturition, feels a desire to pass water very frequently, suffers a good deal of pain in doing so, and passes but a very small quantity each time. This seems to be due in most cases to a complicating cystitis, and not so much to an inflammation of the kidneys as to an acute catarhal inflammation of the mucous membrane of the bladder, which is developed at the same time and complicates the case. In this set of cases the urine is at first very small in quantity, and only a few ounces may be passed in the twenty-four hours, and sometimes for twenty-four, thirty-six, or forty-eight hours there will be absolutely no urine passed at all; there will be complete suppression. In certain cases this suppression of urine may last for a longer time still. There are on record cases in which such a suppression has lasted for many days, or even for weeks, at a time. But most cases only persist for a moderate number of hours, and then the urine reappears. When the urine is passed, we find its color changed by the admixture of blood with it. If the blood is present in large quantity, the urine is distinctly of a bloody-red color; but if it is only in small quantity, the urine will simply be of a brownish or smoky color. Although the urine is passed in such small quantities, yet its specific gravity is regularly diminished. It is lower than it normally is, even when there is an abundance of urine. Albumin is present in very large proportion, and sometimes, when examined, all the urine in the test-tube will seem to be solidified by boiling and by the addition of nitric acid. It is always present in very considerable amount. The blood which gives the color to the urine is found in the urine, when examined by the microscope, either in the form of round blood corpuscles scattered about irregularly in all parts of the field, or else it may appear in the form of blood casts—that is, in little cylindrical accumulations of blood formed in the kidney tubules that have not become disintegrated by their suspension in the urine. All kinds of casts are present during the course of the nephritis; there are hyaline, nucleated, granular, and epithelial casts. Renal epithelium is also present in a considerable number of cases, but this must never be confounded with the epithelium from the bladder and from the pelvis of the kidney, which closely resembles it in appearance, and which is apt to be present because of the catarhal inflammation of the bladder and of the mucous membrane of the pelvis of the kidney.

In this set of cases dropsy is developed within a very short time—usually in the first twenty-four hours, but sometimes not till a little later. It is a dropsy which begins in the face or the legs, and then rapidly spreads over the extremities until it at last involves the subcutaneous conne-

tive tissue throughout the whole body, and with this there may be also an accumulation of fluid within the serous cavities of the peritoneum, the pleura, and the pericardium. So these patients may develop a general dropsy of considerable extent in a very short space of time.

These patients lose their appetites at once, and often there is an addition of more or less nausea, and there may be vomiting. They also develop the peculiar nervous dyspnoea that belongs to the different kinds of Bright's disease, and this may render itself more marked by reason of an accumulation of serum in the pleural cavities, or the setting in of oedema of the lungs, and sometimes by such an oedema complicating a previously existing pleurisy.

Cerebral symptoms are regularly present to a greater or less degree. They are the ordinary cerebral symptoms of Bright's disease—headache, dizziness, stupor alternating with restlessness and an inability to sleep, and sometimes they go on to delirium, and twitches of the voluntary muscles, and general convulsions; and, in very bad cases, the condition of stupor finally deepens into complete unconsciousness or coma.

In some cases the condition of the patient will be rendered still worse by reason of the addition of some complicating inflammation, such as a bronchitis, a broncho-pneumonia, a lobar pneumonia, a pleurisy with the production of fibrin, or else a pleurisy with effusion; or there may be a peritonitis, a pericarditis, or, as an exceptional condition, an endocarditis characterized by the rapid production of vegetations on the valves of the heart. One of the last cases of acute diffuse nephritis which I observed presented this complication, and in this case the course of the disease was rendered somewhat peculiar, from the fact that some of these vegetations on the valves of the heart became detached and found their way into the aorta in considerable numbers, and finally became lodged in the branches of the splenic artery, and so filled up nearly all of them; and, as a result, there was death of nearly the whole spleen. Nearly the whole organ became necrosed as a result of this occlusion of the splenic arteries, and this had been followed by a softening of the spleen, and the necrosed matter had ruptured through the splenic capsule and found its way into the peritoneal cavity, and there set up a general peritonitis, which was the immediate cause of the patient's death. The sequence here was, first, an acute diffuse nephritis, then an acute endocarditis, then a detachment of vegetations from the valves and a filling up of the arteries of the spleen with them, then a necrosis of the spleen and a rupturing of its capsule, and, finally, a setting up of a general peritonitis, which was the immediate cause of death.

There is a good deal of difference in the different cases of this form of acute diffuse nephritis as to the severity of the symptoms. Some cases run a comparatively mild course. They present the different symptoms and the usual number of them, but they show no very great degree of severity. The febrile movement is not very high at any time, the disturbances of the stomach are not very marked, the urine is not suppressed, but only diminished in quantity, the dropsy reaches no very great degree of severity, and the cerebral symptoms manifest themselves only by head-
aches, restlessness, sleeplessness, and stupor, alternating with these other symptoms. But in other cases the symptoms are very well marked indeed. The febrile movement reaches a considerable degree early in the disease, the urine is suppressed absolutely, vomiting is incessant, the dropsey is very considerable in degree, the cerebral symptoms are very marked, there are repeated attacks of convulsions, and the patient finally dies, either in a convolution or in a condition of complete anasarca. So we get in the different cases all sorts of degrees of severity of the development of the different symptoms, though all the symptoms are regularly present, to a greater or less extent, in every case.

In the worst cases the duration of the disease is short, and the patient dies within a few days, or by the end of a week. But in the milder cases the duration is apt to be longer, and the symptoms, after continuing for two or three weeks, then gradually subside. In very mild cases the symptoms sometimes subside very promptly, in two or three weeks from the onset of the disease the patients are apparently entirely well, the dropsey has disappeared, there is no longer any blood in the urine, it is passed in the normal quantities, the appetite returns, the breathing becomes natural, and the general health is improved, but yet the composition of the urine remains abnormal for a long time after, and a small amount of albumin and a few casts can often be found for months after all the other symptoms have disappeared. But in other cases the subsidence of the other symptoms is not so complete. The dropsey does not entirely go away, the appetite remains poor, the patient is still anemic, feels somewhat prostrated and not strong enough to go on with his usual work. These symptoms continue sometimes for months, then it is possible for the kidneys to return to their natural condition again, and the patient gets entirely well at last. Then, too, there are a few cases of acute diffuse nephritis which constantly present very marked symptoms, and yet the prognosis is really good, and the patient will ultimately get entirely well. Most of these severe cases, however, die. Some of them die in convulsions, some comatose, some from one of the complicating inflammations, and, finally, some of them go on to have chronic diffuse nephritis.

As regards the treatment of this class of patients, the first thing to be done is to put them to bed. Usually they are ready enough to go to bed without any persuasion, for they feel distinctly sick, as in cases of acute inflammation of one of the viscera. After getting them to bed, you may then put them on a fluid diet, usually of milk, and after that you must pay attention to the condition of the kidneys. About the only way we seem to be able to exert any direct influence over the inflammation of the kidneys is by the use of counter-irritation to the skin over the position of the kidneys—that is, in the lumbar region. There are several different ways of applying counter-irritation. If the patient is strong and robust, we may take blood pretty freely by means of cups. Thus from four to six wet cups may be applied to the back, and you may abstract all the blood you can in this way; and then, after they have ceased drawing and have been taken off, you may apply a hot poultice over the same region, so that the blood may continue to flow for a longer time, and by this means you also are doing good by applying heat and moisture to the inflamed kidneys. If, however, the patient is not strong enough to warrant you in taking blood, then you may make use of dry instead of wet cups, and, after removing them, apply the hot poultice as before. Poultices or hot fomentations over the region of the kidneys do seem to have a real effect in controlling the congestion of the kidneys, and the same thing is true of dry and wet cuppings. So if in any case you can not employ cups at all, then you can make use of hot fomentations alone with good effect.

A large flaxseed poultice, big enough to cover the whole lumbar region, answers tolerably well for this purpose. But a more effective means is by the use of a poultice made of sponge-pilpine, a preparation of sponge spread out on a rubber surface, and this makes a very convenient means of applying heat in these cases. The best way of preparing it is to cut a piece of sponge-pilpine about a foot square, and then put this in a basin of boiling water, and, as it is too hot for the hands, the sponge-pilpine must be handled with forceps; then, besides, you should have ready a towel and an ordinary wringing-machine, such as is used in laundries, with two rollers rubbing on each other and turned by means of a crank; then take the sponge-pilpine out of the water, put it in the towel and pass it through the ringing-machine, and then put it at once on the patient's back. In this way you can apply a greater degree of heat than you are able to apply in any other way. After the first application has cooled off you can put on another and repeat it as often as necessary. If these remedies act as you wish them, by diminishing the congestion of the kidneys, the evidence of this is an increase in the amount of urine becoming apparent within a few hours after the application of the cups and the heat, and if within a reasonable time there is no such increase in the urine, it is probable that these remedies have failed to act. Another way by which you can try to effect the same result is by putting the patient in a hot-air bath and so applying heat to the whole surface of the skin, and in this way you may relieve the congestion of the kidneys. And by this treatment you sometimes effect a double purpose, not only by relieving the congestion of the kidneys, but also by relieving the venous congestion over the whole body by taking away a certain amount of the serum of the blood. Where you are dealing with children you can put them into an ordinary warm bath, and then, on taking them out, wrap them up warmly in a number of blankets, and so allow them to sweat. These seem to be the most efficient remedies at our disposal for endeavoring to remove or diminish the intensity of the inflammation of the kidneys. Then, besides these measures, you can try to act on the bowels, and for this purpose you can give cathartics. And if you can not produce the desired effects in any other way, you can still try the hypodermic injection of pilocarpine. As the patient gets better of the renal disturbances, then you should give your attention to building up the general health, and warn the patient to take care that he does not have a relapse from any imprudence or undue exposure.

REFUSION

IN

CARBONIC-OXIDE POISONING.*

By WILLIAM S. HALSTED, M.D.,

ASSISTANT SURGEON TO THE ROOSEVELT HOSPITAL.

Contributions to the treatment of patients poisoned by carbonic-oxide, the most noxious constituent of coal and illuminating gases, are especially worthy of consideration because of the great frequency of and mortality from this form of poisoning. In Adolph Lesser's† tables carbonic oxide figures as the most common poison, and the one which yields the highest percentage of fatal cases.

Refusion of blood is literally a depletory transfusion, in which the blood withdrawn is returned to the circulation of the loser. Volkman,‡ in discussing exarticulation at the hip joint, suggests the feasibility of catching the blood lost, peradventure, in this operation, and returning it to the loser through the divided femoral vein. And Esmarch§ has, in one instance, endeavored to act in accordance with Volkman's suggestion, but his patient died while preparations were being made for transfusion. Huetter,|| in frost-gauging of both feet, transfused centrifugally 350 c.e. of the patient's own blood, defibrinated, into the left posterior tibial artery, and believed that he thereby preserved a portion of the frozen part. The right foot, untransfused, underwent an extensive forfeiture.

Highmore,¶ evidently not aware that it had already occurred to others to refund blood, offers "remarks on an overlooked source of blood supply for transfusion in post-partum haemorrhage," and recommends utilizing the blood lost by the mother. Other than these I know of no hints or attempts at refusion.

In carbonic-oxide poisoning, refusion involves an additional factor, viz.: the oxygenation of the poisoned blood employed; and is, therefore, an infusion of the purified, defibrinated for the poisoned, entire blood of the individual.

A most radical case of refusion is the following:

On the 15th of last May, Mr. A. S. G., aged fifty-seven, a man of medium size and good physique, was found unconscious in a state-room of the steamer Bristol by the ticket-taker, who observed a strong smell of gas in the room. He was taken in an ambulance to the Chambers Street Hospital, where he arrived at 9.05 a.m. The house-surgeon states that, on admission, the patient could not be aroused. Respirations superficial; pulse fairly strong, and 85 beats a minute; temperature not taken. Skin pale and cold; lips slate-colored; pupils somewhat dilated. Was put in a hot-air bath and given whisky hypodermically. At 10.30 a.m., when I first saw the patient, he was still comatose. His eyes were partly open, and his pupils equal, slightly contracted, and irresponsible to light; face ashy pale, and surface of body cold. The respirations, 29 a minute, were abdominal and so superficial that it was almost impossible to count them; pulse 96, small and easily compressible. Feeble conjunctival and plantar reflexes; other superficial reflexes absent, except cremasteric on left side. Deep reflexes could not be tested because of the rigidity which existed. Both arms were flexed; the right more strongly than the left. 10.50 a.m.: right radial artery exposed above wrist for about one inch, and two ligatures passed under it.

A cannula, introduced centripetically into the artery, was held in place by one ligature; the other was used to obviate the vessel peripherally. Through the cannula 512 c.c. of blood were withdrawn, defibrinated, strained, and kept at a temperature of about 37°-5° C. in a transfusion apparatus similar to that which is before you. 11.20 a.m.: temperature 35°4° C. (95°8° F.), pulse 92, respiration 22, full and dyspnoic. Superficial reflexes well pronounced. Eyes closed, but patient can be made to open them. Rigidity of limbs has, in great measure, disappeared. 11.32 a.m., 288 c.c. of defibrinated blood, all that could be obtained from the 512 ccm., were refunded through the cannula in the artery toward the heart—centripetal arterial infusion. At 11.45 the injection was completed. Temperature 36°4° C. (98° F.), pulse 104, respirations 28, deep and labored. Superficial reflexes possibly exaggerated. The usual post-transfusion rigor lasted for half an hour. 12.35 p.m.: 300 c.c. withdrawn, as before, through the cannula, defibrinated and mixed with 128 c.c. of defibrinated blood taken from another patient. 1 p.m.: temperature 38°2° C. (100°8° F.), pulse 128, respiration 28. 1.05 p.m.: patient's pallor most striking; 192 c.c. of the mixed blood infused. The color returned rapidly to his face when from 80 to 100 c.c. had been injected, the change from a deathly white to a healthy red taking place in a few seconds. 1.13: temperature 39°1°, pulse 120, respiration 40. 2.30: temperature 39°4°, pulse 140, respiration 40. 5.20: temperature 37°8°, pulse 116, respiration 20.

Patient has been gradually returning to consciousness since the first venesection, and now attempts to get out of bed. May 6th.—12.15 p.m.: urine voided voluntarily for the first time since admission, it having previously been drawn with a catheter.

8.20 a.m.: temperature 37° (normal), pulse 98, respirations 20. Patient in good condition, but mentally still a little dull. 4.30 p.m.: patient eats well, and desires to go home.

May 7th.—Intelect perfectly clear; remembers that the steward lighted the gas in his state-room about 9.30 p.m., the night previous to his poisoning, but that it went out as the door was closed. Undressed himself in the dark, went to bed, and can recall nothing of the night. Has experienced none of the unpleasant after-effects of the poisoning.

Allowed to go home to Wareham, Mass., about 50 hours after admission. . . . October 24th, have to this day, 54 months after the poisoning, interviewed Mr. A. S. G., and ascertained that he has not had a single unpleasant symptom referable to the effect of the gas.

That this patient would have recovered without such active treatment is not improbable. It is, nevertheless, certain that the blood-letting exerted a most favorable influence, changing almost instantly the entire aspect of the case. The scarcely perceptible respirations became at once conspicuously full; in a few moments the absent superficial
reflexes had returned and the rigid arms relaxed. The body-surface grew gradually warmer, and, after the first infusion, the temperature had risen from 35.4° C. to 36° C. The pulse and respirations kept pace with the temperature. The first infusion prepared the subject for a second depletion, and contributed to the rise in temperature, and, probably, to the improved circulation. The second infusion was decidedly indicated, as evidenced by the impression it produced in the patient's color.

In the light of Kühne's* experiments on animals, it is a question whether the blood-letting alone would not have rescued all the cases of carbonic-oxide poisoning in the human subject in which a deleterious transfusion has been successful. Kühne (loc. cit.) has found that venesection of itself could save life if the respirations were as much as two in a minute. From twenty-three cases of transfusion for carbonic-oxide poisoning, of which I have notes, twelve terminated favorably. In two (Cases, one; Lühde,‡ one) of the twelve successful cases very small quantities of blood were transfused, and without any immediate good effects. In one (Hüttê§) of the remaining cases attempts at depletion were unsuccessful, only a few drops of blood having been withdrawn. In three cases (Garrigues,¶ one; Halsted, two) the venesection exerted a decidedly favorable influence. Three cases (Badl,† one; Martin,¶ one; Lehmann,¶ one) are narrated in articles to which I have not access, and so cannot arrive at any positive conclusions as to which was the more efficacious agent, the venesection or the transfusion. In one case (König ¶) the venesection (the amount of blood withdrawn is not stated) was attended with slight, and the transfusion with no success. The remaining two cases (Jürgensen,¶ one; Saltzmann,** one) were apparently benefited by the transfusion, and yet in neither is any reference made to the influence of the depletion, although from one (Jürgensen) 400 c.e., and from the other (Saltzmann) 180 ccm., of blood were abstracted.

Some, then, of the cases claimed for transfusion seem attributable to the venesection which preceded it; and in no instance has it seemed to me clearly demonstrable that transfusion has saved life where venesection had failed.

A few cases are reported by O. Kahler,¶¶ Marten,¶¶ and others, of venesection in carbonaceous with good results.

And, of the several cases which have come under my care, I will cite briefly, in proof of the efficacy of venesection, the most serious (one in which deleterious transfusion was resorted to):

On May 5, 1882, at 10.10 A.M., Lilie Bent, a robust girl of seventeen, was admitted to Chambers Street Hospital, suffering from illuminating-gas poisoning. The night before, on retiring, she is supposed to have blown out the gas in her state-room on the steamers Providence.

On admission, she is said to have been unconscious, moaning, and much cyanosed. Her respirations were shallow, and her pulse rapid and feeble. Temperature not taken.

Whisky and digitalis were given hypodermically. She was put in a hot-air bath and hot clothes were applied to the precordia. Flagellation and the inhalation of ammonia would partially arouse her. Artificial respiration was tried, but with what effect is not stated. She would improve temporarily under the treatment, but when left alone returned to her previous condition.

I saw her about 5 P.M. Her temperature was 39.1° C., respiration 40, and pulse 120. Advised washing the stomach and large intestine with hot water for the purpose of further stimulation.

9 P.M.: Patient much worse. Pulse feeble, more rapid and intermittent; respirations very superficial; conjunctive insensitive and all reflexes absent; mouth foamy; occasional facial twitchings and grinding of the teeth; arms and legs rigid—the flexor muscles overpowering the extensors.

6.09 P.M.: 204 c.c. of blood withdrawn from left basilic vein; upon this the condition of the patient improved marvelously; almost instantly her respirations became full and her pulse strong and less rapid. The rigidity of her limbs disappeared, her reflexes returned, and she could be aroused by shaking or speaking loudly to her.

11 P.M.: Attempted to transfuse entire blood from a Bechter's apparatus into patient's right cephalic vein, but failed to introduce more than 50 c.c.

May 6th.—During the night nourishment was administered per rectum. At 6 A.M. patient answers questions somewhat intelligently, and at 9 A.M. takes nourishment by the mouth.

May 7th.—Feels well but weak.

It is difficult in any case to know precisely how much of the cure should be attributed to the treatment. When, however, a case like the one just narrated, observed sufficiently long to exclude fluctuation, assumes a decidedly more serious aspect, and then is, almost instantly, on treatment, transformed into rapid convalescence, one feels justified in assigning a cause to the effect.

Many apparently severe cases of carbonic-oxide poisoning are recorded, which have recovered more or less promptly when exposed to fresh air and stimulation. Some, too, where oxygen is believed to have hastened the convalescence. But if, despite these measures, the patient's condition grows constantly worse, death is virtually certain, unless venesection be resorted to.
From the hour of her admission until she was bled—eleven hours—Lillie Bent's condition was growing gradually worse, and ultimately became so bad that her case seemed hopeless; this, in a moment, upon venesection, was transformed into one of apparently certain recovery.

The transfusion produced no appreciable effect, as might have been expected from the small amount of blood injected.

As additional proof of the value of bleeding in carbonic-oxide poisoning, I might allude to the case of her illicit companion, who, occupying the state-room with her, was likewise poisoned. Less seriously affected by the gas, he was venesected while convalescing. Maniacal and confined in a strait-jacket, he was bled about 512 c. c., and thereupon became so rational and docile that it was no longer necessary to restrain him.

To cite, as I might, other less serious cases in which the beneficial effect of blood-letting was less strikingly apparent would be superfluous.

Why, then, transfuse if venesection accomplishes so much? If for no other reason, to allow of repeated venesection. The poisoned individual should be bled freely, unless there be decided contra-indications, even after, to all appearances, out of danger, in the hope of diminishing the risk of pernicious after-effects.

Although bleeding of itself will probably suffice to save life in almost all cases which occur in practice, it has been demonstrated by Kühne (l. c.) that animals, poisoned beyond hope of rescue by venesection, can be saved by transfusion. In one of his experiments, where respiration had been suspended seven minutes, he was still able to restore life to the animal by the infusion of defibrinated blood.

Aside from experimental demonstrations of the value of transfusion in cases beyond recall by means of bleeding, nothing could be theoretically much more enticing than the plausibility of substituting blood corpuscles capable of taking up oxygen for such as are incapacitated from so doing by reason of the somewhat stable compound which carbonic-oxide forms with their hemoglobin. Thus the much quoted and meritorious experiments of Panum * have led his partisans to believe in the possibility of blood substitution and to regard the blood corpuscles as something which can be taken from one individual and transplanted in another.

But von Ott † has shown the falsity of Panum's deductions, inasmuch as he could obtain like results, although making use of a fluid which contained no morphological elements.

Von Ott (l. c.) has demonstrated, furthermore, that blood corpuscles infused into the circulation are short lived, and that blood, whether entire or defibrinated, for other reasons, is not only no better than but not as good as a 0.06-per-cent. saline solution for transfusion in acute anemia. One can not, therefore, properly speak of a substitution as transplantation of blood corpuscles by infusion of them into an impoverished circulation.

Fortunately, however, in carbonic-oxide poisoning it is merely necessary to sustain the patient artificially for a brief period, and for this, undoubtedly, the infused corpuscles can serve as oxygen carriers for a sufficiently long time. For the circumstance, as von Ott's (l. c.) experiments teach us, that the infused corpuscles do not become integral constituents of the new organism, but rather are destined to a more or less rapid disintegration and elimination, does not prevent them from circulating and temporarily taking part in the interchange of gases. Clear, then, as are the indications for transfusion auxiliary to venesection in the treatment of the cases under consideration, the extreme difficulty of obtaining blood at all, to say nothing of sufficient quantity, has, up to the present time, classified the operation with the rarer therapeutic procedures. And we might, indeed, in the treatment of these cases, content ourselves with blood-letting were it not that the practicability of refusion removes what has been, perhaps, the greatest obstacle to the performance of transfusion.

To the investigations of Hermann, Donders, ‡ and Podolski † I owe the conception of reforming the purified for the poisoned blood of the victim to carbonic-oxide poisoning. Hermann ‡ calls attention to the fact that nitrogen monoxide can liberate the carbonic oxide of the carbon-oxy-hemoglobin, and forms a stronger combination with hemoglobin than carbonic oxide does; and, subsequently, Donders (l. c.), Hermann, and Podolski (l. c.) find that oxygen or air can, in a few minutes, free hemoglobin from carbonic oxide if passed forcibly in large quantities through the poisoned blood.

As to the best method of infusing fluids into the circulation, good authorities disagree. Of the four possible methods, centrifugally or centripetally into an artery or vein, the question of centrifugal venous infusion is entertained only to be discarded. Haeter, who gives to von Graefe the honor of being the first to draw attention to centrifugal arterial transfusion, deserves the credit of having introduced it to the profession, and strongly advocated the method.

Landois, * too, while contrasting, in general, arterial with venous transfusion, prefers, from a physiological standpoint, the arterial, be it centripetal or centrifugal.

Cohnheim, † on the other hand, expresses himself decidedly against centrifugal arterial transfusion essentially as follows: One should surely under no circumstances inject peripherally into an artery; for the peripheral arterial branches contract with such energy against the foreign blood which is entering them that it is often necessary, in order to overcome the resistance, to exercise pressure sufficiently forcible to rupture the blood-vessels. The case is very different when one injects centripetally into an artery and employs no more pressure than is required to overcome the existing arterial tension. The blood infused mingles at once with that which is already present in the artery and flows, without resistance, into the first branch above, thence into its arterial and capillary ramifications, and from here on, under normal venous pressure, to the heart.

‡ “Arch. für Anat. und Phys.,” 1869.
† “Vorlesungen über allgemeine Pathologie,” Bd. i, p. 424.
Kümmel,§ Schede's assistant, produced gangrene of the hand by the centrifugal infusion of a saline solution into the radial artery, thus giving us a demonstration of a disaster which may attend this method, and which he might have foreseen.

We are, then, restricted to the choice between centripetal arterial and centripetal venous infusion.

Hütter's † arguments for peripheral or centrifugal arterial transfusion hold good for centripetal arterial infusion. He prefers the arterial to the venous transfusion, because the blood by the former method courses slower and more uniformly to the heart; because the minutest air-vesicle is retained in the capillaries; and because the danger of phlebitis is avoided.

Landois (I. c.) adds to these advantages another, viz.: that the capillary system, like a supplementary filter, catches all foreign particles which may be present.

The essential advantages of centripetal arterial transfusion in profound asphyxia, says Landois (I. c.), can be summed up as follows: 1. Arterial blood is thus most directly dispatched to the nerve-centers, in consequence of which the venous blood there contained is propelled onward into the veins; and 2. The filling of the arterial system rejuvenates the feeble circulation by creating a considerable difference in pressure between the arterial and venous systems.

Cohnheim (I. c.), too, from his experiments on animals, declares the central or centripetal arterial transfusion to be the least dangerous, and at the same time most completely effectual procedure.

From a practical standpoint, I am also impelled to advocate centripetal arterial transfusion.

Besides the case already narrated, it has been my good fortune to transfuse by this method with most brilliant and unexpected success in two cases—one of acute anemia and one of septicemia.

Joseph Hart, aged eleven years, was admitted to Roosevelt Hospital, September 15, 1882, for a compound comminuted fracture of the tibia and some of the tarsal bones. The ankle joint was involved in the injury, and the soft parts were badly mangled. The wheel of a street-car had passed over his leg the night before. Patient is said to have lost much blood, and the clothes in which his leg was wrapped furnished evidence to that effect. The parents would not consent to an amputation, and the boy, although perfectly conscious and able to give an account of himself, was not in condition for it.

At 8.30 p. m.—eleven or twelve hours after admission—the patient was cold and unconscious, and his pulse was so rapid and feeble that it could not be counted satisfactorily. It was estimated to be about 150 per minute. I injected 192 c. c. of a salt solution (chloride of sodium 5 ; water, 0, j) centripetally into the left radial artery, whereupon the pulse became quite full, and 135 a minute. The boy regained consciousness immediately, and his condition seemed to warrant an attempt at amputation—permission to do so having, meanwhile, been obtained. The administration of ether had such a bad effect on the pulse that the operation was deferred, and the leg placed in a hot-water bath. The patient continued to improve, and survived an amputation of the leg, performed by Dr. Sands, twenty-five days after admission.

On the 18th of March, 1883, at Ward's Island, I infused defibrinated blood centripetally into the radial artery, in a case of septicemia.

The patient, an Italian, about forty years of age, had suffered for several months from a suppulsive disease of the ankle and some of the tarsal joints. For about one week prior to the operation he had, almost daily, well-pronounced rigors and a temperature ranging from about 36°1 C. (97° F.) to 40°6 C. (105° F.). He was so feeble that to amputate was deemed inadvisable even as a last resort. A depletory transfusion was accordingly undertaken. A stout philanthropic German offered to furnish the blood. So plentiful was his subcutaneous fat that not a vein could be seen, although his arm had been carefully constricted below the point at which the basilic vein usually perforates the deep fascia. Dissection for a vein, prolonged until even the would-be donor appeared willing to have the search discontinued, failed to discover one. Thereupon the radial artery was exposed without difficulty, although our subject fainted as the incision was being made through the integument, and so necessitated the completion of the operation upon the floor. The Italian was next depleted through his right radial artery until the arterial tension was barely sufficient to throw a jet across the graduated jar, into which 178 c.e. had been allowed to flow.

Immediately thereupon 186 c.e. of defibrinated blood was infused centripetally into the artery. In a few moments the patient's pulse had fallen to 120, which was eight beats better to the minute than before the administration of ether. The leg was then amputated just below its middle. Patient's pulse 112-114, weak, but regular, and better than before the amputation.

Cardiac stimulants were, of course, freely administered. Slight post-transfusion rigor and a temperature of 38° 8 C. On the following morning, March 19th, patient's pulse was 110, and temperature normal. Since then uninterrupted convalescence.

It is only just to add that I have once done centripetal arterial infusion, in a desperate case of pyaemia, where the fatal termination was probably precipitated by the operation.

If the infusion of defibrinated blood influenced the action of the heart unfavorably, it certainly was, in part, to be explained by the too heroic depletion which preceded it.

This unsuccessful attempt should not militate against the method of injecting the blood, but rather against the indication for so doing, or against the manner or extent of the depletion. The main argument of those who prefer centripetal venous to centripetal arterial infusion is that the former is the simpler. If it be true that the latter is, in any degree, the safer method, the simplicity of the former does not deserve to be considered. Furthermore, instead of being easier, I am sure that it is often more difficult to discover a vein than to expose the radial artery. It was, for instance, impossible to discover a vein in the stout German referred to in this paper. Jennings,⁷ too, one of the more recent advocates of the intravenous method, without having practiced the arterial, had considerable difficulty in finding a vein in one instance, and others testify to the same experience. The dangers of intravenous

---

† Langenbeek's "Archiv," Bd. xii.
infusion, such as the introduction of air and small clots, and the overpowering of the heart by a too rapid injection, may be, theoretically, easy to avoid, but, practically, death has frequently been brought about by one or more of these causes.

To the centripetal arterial infusion pertain, theoretically, none of the dangers which, practically, in the intravenous method, are far from always to be avoided. And, from a practical stand-point, my cases, which, I believe, are the first recorded, induce me to advocate the centripetal arterial method.

**Tonic Spasm of the Trapezius Muscle of Malarial (?) Origin.**

*By L. Emmett Holt, A. M., M. D., New York, attending physician to the Children's Department of the Northwestern Dispensary.*

Joseph R., eleven years of age, presented himself at my dispensary clinic on Monday, September 24, 1883. He stated that he had been as well as usual on the Saturday previous; went to bed all right, but awoke in the middle of the night and found his neck drawn to the right side, and so stiff that he could not move the head in any direction. There was no history of exposure, and no draught in the sleeping-room, the windows being all closed. He felt no pain whatever. The spasm had continued from that time until I saw him. The only change he had noticed was that he thought it was less marked on Sunday and Monday mornings than in the afternoons, as he had been able at those times to move the head slightly. The only pain he had experienced at any time was when attempts at movement of the head were made. The bowels were constipated. He thought no febrile movement had been present. On examination, quite a unique deformity was found. The right shoulder was elevated fully three inches higher than the left, and the head was drawn downward so as nearly to meet it, deviating fully 45° from the vertical. His clothing was removed with a good deal of difficulty. The anterior border of the trapezius stood out very prominently at the side of the neck, and its fibers were very tense and hard. The middle fibers were also rigid, while the lower ones did not seem to be at all affected. The right scapula was nearer to the spine than the left, and its inferior angle was more prominent.

The spine presented a well-marked double curve to the left in the cervical region and to the right in the dorsal. The dorsal curve was the greater, and looked precisely like an old lateral curvature. Viewed in front, the head was seen to be slightly rotated to the left and the chin a little elevated. Neither of the sterno-mastoid muscles was prominent or rigid. The head was held absolutely fixed in this position; voluntary attempts to straighten it brought out the sterno-mastoid muscles prominently, but made no visible change in the deformity. Passive movements were alike without effect, and produced pain. There was no tenderness found along the spine, over the trapezius muscle, or anywhere about the shoulder.

The patient's general condition was quite good. He was fairly nourished, and perhaps a little anaemic. The tongue was coated; buccal temperature 100-3° F.; spleen very much enlarged.

The acuteness of the invasion seemed to preclude the possibility of any bone disease. The absence of any history of exposure, and of all muscular tenderness and pain, was thought sufficient to exclude any rheumatic element from the case. The constipation, the splenic enlargement, the slight fever, suggested the possibility that malarial poisoning might be the cause, especially as he lived in a district well known to be malarial. At all events, this view was adopted as a working hypothesis, and a mercurial cathartic and cinchonidine were ordered.

I took him at once to a photographer, but failed to get a picture, as the day was a stormy one. I directed him then to take no cinchonidine until he had been photographed the following morning. He promised faithfully; but, failing, doubtless, to see the force of the injunction, took ten grains of cinchonidine that night, and twenty more the following morning, before the accompanying photographs were taken. Whether from the effect of the medicine or not, very marked improvement had in the mean time taken place. The deformity of the previous day is only feebly portrayed. It was the same in kind as that shown in the cuts, but much exaggerated in all particulars. Another circumstance which militated against us was the fact that the artist thought we wanted the photographs to show the result of treatment, and apologized for the picture, saying that he tried his best to make the boy stand straight, but that he would keep the right shoulder raised in spite of him, after he had gone to
MILLER: FRENCH BRANDY.

[Caption: FIG. 2.]

him several times and pushed it down forcibly. I mention this fact as the prominence of the left sterno-mastoid, which is shown in the cut, was not present when I saw the case, and is evidently caused by the attempt to hold the head erect.

I examined the boy that same afternoon and found that the rigidity had, in a great measure, disappeared. It required close inspection to detect any deformity. He took no more medicine; his symptoms did not return. I examined him critically four days later. No trace of the deformity existed. The spine was straight, and its movements, as those of the neck, were perfect.

I called at the house a month later and learned there had been no relapse.

Remarks.—The etiology of these cases of tonic muscular spasm is a matter often of great obscurity, as nearly all authors on nervous diseases agree. The cases which develop gradually are more easily explained than those which come on suddenly, like the one reported. In the former, cervical bone disease, central brain and cord lesions are often found to be the cause. The latter are generally attributed to cold or to some reflex influence which may come from the teeth, the stomach, intestinal worms, uterus, etc. They are occasionally seen as sequelae of the eruptive fevers, especially scarlatina. A few years ago Bohn published two cases which were referred to malarial poisoning. One was in a girl of five years, and accompanied the paroxysms of a tertian intermittent. The other was in a child of two years, and was quotidian. Similar cases have also been mentioned by Steiner, Bouchaud, and Romberg. I have been unable to find that any have been recorded in this country except one that I myself reported in another connection.*

This was a case of spasm of the sterno-mastoid which left very little room for doubt in regard to its malarial origin. It occurred in a boy of eight years, who had had a well-marked malarial paroxysm, coming on every afternoon for two or three days, accompanied with torticollis. This disappeared during the night, and in the morning the neck was perfectly movable, and remained so until about two o'clock, when the symptoms came back as before. Two paroxysms were witnessed before any active treatment was begun, in order to settle the question of diagnosis. Quinine was then administered in full doses, with the effect of controlling completely both the torticollis and the constitutional symptoms. A little tenderness was present over the muscle in this case, but no pain except on attempts at movement. There was much splenic enlargement. The quinine was kept up for a few days after the symptoms subsided, and then stopped. The case was seen one month later, and no relapse had occurred.

In the case which forms the subject of this article I do not think the evidence sufficiently strong for one to say positively that the cause was malaria. That an obscure case is relieved promptly by quinine is by no means conclusive proof that it depended upon this poison, although this is an inference which is too often drawn.

To my mind it furnishes, in this instance, a very strong presumption, especially when taken in connection with the slight febrile movement and the marked splenic enlargement. A second point of interest in this case is its rarity. Tonic spasm of the sterno-mastoid is very common. It is not very infrequent to find a part of the trapezius also affected in cases of torticollis. A spasm of this latter muscle alone is, however, according to almost all the authors on nervous diseases, of exceedingly rare occurrence. The only picture of the deformity which I have been able to find is given by Ross, and taken from Duchenne. This shows a lateral deflection of the head, but the shoulder is not raised, and it conveys but a very imperfect idea of the affection.

200 West Fifty-second Street.

FRENCH BRANDY.†

By ADOLPH W. MILLER, M. D., Ph. D.,
PHILADELPHIA.

The U. S. Pharmacopoeia of 1880 has retained Spiritus vinis Gallici as one of its official preparations. It is described there as an alcoholic liquid, obtained by the distillation of fermented grapes, and it is required that it must be at least four years old. An announcement recently made by the American consul at La Rochelle, in the wine-producing district of France, will no doubt sorely distress those who are

* "Am. Jour. of Obst. and Dis. of Women and Children," April, 1883, "Malaria in Children."
† Read at the annual meeting of the Alumni Association of the Auxiliary Department of Medicine of the University of Pennsylvania.
It becomes evident from the foregoing that brandy is a very complex and indefinite compound, each specimen of which differs from every other not only in alcoholic strength, but also in the proportion of every one of its component parts. It seems, indeed, to be uniform only in the one fact of perpetual adulteration. As one of the chief objects of the pharmacopoeia has been to secure accuracy and precision in the proportions of its compounds, it appears somewhat anomalous that the indefinite liquors—brandy and whisky—have not been expunged and replaced by a pure spirit of definite alcoholic strength. This becomes the more remarkable when an article of almost chemical purity can be so readily obtained at a mere fraction of the cost of the flavored liquors. The article known commercially as rectified spirit, French spirit, or sweet liquor, is produced by slowly percolating grain whisky, the so-called high-wines of the distillers, through large tanks containing granulated charcoal. Every particle of coloring and flavoring material, all the fusel oils, the amylc and other higher alcohols, are thus removed, and the spirit is thus rendered clean and sweet. The substance is in fact specially prepared for the art of compounding liquors, and, to accomplish this purpose successfully, it is essential that this basis must be absolutely devoid of any inherent flavor of its own, so as not to mar the bouquet of any of the cordials, wines, gins, brandies, etc., which are to be constructed out of it.

The medical authorities are unanimous in their condemnation of the various fusel oils, or higher alcohols produced during vinous fermentation. When these have been carefully removed from either brandy or wine, there remains simply pure 50 per cent. ethylic alcohol, entirely analogous to and identical with commercial sweet liquor. This substance, for which the title spiritus magalis rectificatus would seem to be appropriate, may therefore be regarded as a pure alcoholic stimulant, free from many of the objections which may be urged against other forms. It is to be regretted that this article has not been made official in the new pharmacopoeia in place of the impure forms which have there found recognition.

Possibly it may not yet be generally known that the new pharmacopoeia has given its official sanction to a flavored alcoholic cordial, the elixir aurantii. It was introduced as a substitute for the famous old Dutch liquor known as Curacao. When this elixir was recently made by the first-course students in the pharmaceutical laboratory of the University of Pennsylvania, the official process was found to present no difficulties whatsoever. The resulting preparation proved to be highly aromatic and quite agreeable to even the most fastidious palate. Altogether, it is to be regarded as a desirable acquisition, both as an adjuvant or, per se, as an aromatic alcoholic stimulant.

HONORS TO SCIENTIFIC INVESTIGATORS.—The "Lancet" states that a Royal Society medal has been presented to Professor J. S. Burdon Sanderson, M. D., F. R. S., for the eminent services which he has rendered to physiology and pathology, especially for his investigation of the relations of micro-organisms to disease, and for his researches on the electrical phenomena of plants. The same journal says that the Copley medal has been awarded to Sir William Thomson, F. R. S., for his discovery of the law of the universal dissipation of energy and his researches in physics.
MEDICAL LEGISLATION IN VIRGINIA.

The "Virginia Medical Monthly" very properly calls upon its readers within the limits of the State of Virginia to use their best endeavors to place certain proposed measures in their true light before the newly elected legislators. This, as we have urged upon the profession in New York, is almost the only way of securing an intelligent consideration of medical matters by members of a law-making body. When the session has once begun, as our contemporary remarks, their time is so taken up with political fencing that they have but little opportunity of looking into the merits of any measure regarding questions of which they can not pretend to much personal knowledge. Sanitation and the relations of practitioners of medicine to the community are subjects which, as a matter of course, they must study chiefly, if at all, with the aid of skilled testimony, and that should be all before them before they are called upon to act.

Virginia has had a State Board of Health for the past twelve years, but, by express provision in the act creating it, its members receive no remuneration, nor have they the control of any fund to draw upon for defraying the ordinary expenses incident to carrying out their decisions. If such a board is worth having, plainly it is worth paying for; and we cannot suppose that the General Assembly created a board which it considered not to be worth having. Not only should a fund be voted on which the board could draw for the expenses of its work, but, in addition, the members of the board should receive a substantial remuneration. We do not doubt that the present incumbents give their services cheerfully, or that they work heartily in the cause of sanitation without hope of reward; but we have had enough in this country of the miserable principle that medical services should be rendered to the State without a quid pro quo.

Another matter likely to come up before the Legislature is the proposition to establish a State board of medical examiners, a measure for which, it seems, the profession in Virginia has been petitioning for several years. The interests of inferior medical colleges and those of charlatans are all that can oppose such a provision, if it is drawn up with a fair amount of carefulness; and, in so conservative a State as Virginia, neither of these two interests ought to be very formidable. It must be that any real repugnance on the part of its legislators to enact a law establishing such a board has no more substantial foundation than a misapprehension that might easily be brushed away by individual effort put forth by the leading physicians of the State.

Our contemporary states that a number of other measures of practical interest to the medical profession are likely to be brought before the Legislature, including a pharmacy bill. As we know nothing of the character of the proposed bill, we can only say that the fact of its emanating from the Virginia Pharmaceutical Association is prima facie evidence of its merit.

TEACHERS OF MEDICINE AS STATE EXAMINERS.

Much of the good that a great many people hope for from the creation of State boards of medical examiners—and we have not concealed that we shared their expectation—is undoubtedly contingent on the constitution of such boards and on the way in which their work is carried out. When the first draft of the Erie County society's bill was under discussion at a meeting of that body last summer, the feeling seemed to prevail that teachers of medicine had better be excluded from the proposed board. There can be only one good reason for such a feeling, namely, that an examiner connected with a medical school would be exposed to the temptation to favor the graduates of that school, reserving his severity for others. This objection can be done away with at the start, for it is perfectly practicable to provide by the terms of the law that no applicant's individuality shall be known to any of his examiners until after the votes are all in.

Moreover, it can scarcely be questioned that material advantages would be gained by having the examinations conducted by persons accustomed to such work, that is, persons who are or have been engaged in teaching medicine. In this matter a hint may be taken from the experience of our Canadian neighbors. It seems that the license examination, as practiced in the Province of Quebec, is at present highly unsatisfactory, according to the "Canada Medical and Surgical Journal." The preliminary examination—that on which a man's fitness to begin the study of medicine is made to turn—is all that could be wished for. The curious anomaly is presented, however, of a license examination, conducted, as we understand, by the same board, for the purpose of satisfying the State of the applicant's proper preparation for actual practice, so hasty and superficial as to make it a matter of congratulation with the journal in question that most of the applicants have already received the university degree, so that ordinarily no great harm is done.

Now, if the profession in the State of New York expects anything from the establishment of a State board, and if the State itself expects anything from such a measure, it is, that a higher standard shall be set up and enforced than the State can have any guarantee is or will be enforced by the colleges in the present state of things. Few, we take it, look for any higher or more searching requirements than the best of our colleges now adhere to, but most of us would like to see some legislative action taken to restrain inefficient and unscrupulous colleges from conferring the license to practice with no other controlling provision than their own sense of propriety or their feeling of what is for their interest as corporations.

It may well be doubted if the examinations that are insisted upon by our leading colleges, not only in this State, but elsewhere, are not considerably in advance of any that would be likely to be carried on by men chosen to the exclusion of college
professors. This doubt argues no conviction that great learning, or learning sufficient for the purpose, is by any means confined to the professors; it simply implies the plausible assumption that learning is not all that is requisite in an examiner. He should have an over-present sense of what a young graduate may reasonably be expected to know, and of what he can not fairly be supposed to know; and, further, he should be able to ascertain precisely how much of the former he really does know, and that, too, without worrying him unnecessarily or consuming an undue amount of time in applying the tests. The experience of college professors leads them to just this discrimination and skill, and, while these acquirements may not be confined to them alone, the probability of their possessing them seems so great that their formal exclusion from an examining board would unquestionably be detrimental to the board's efficiency.

CONSUMPTION AS A PREVENTABLE DISEASE.

It can scarcely be said that the subject of the prevention of infectious diseases has not been accorded a prominent place in the discussions at medical gatherings, or in the periodical literature of medicine, for a number of years past. But, assuredly, this prominence is justified by the magnitude of the interests involved. It is not our present intention to raise any new questions bearing upon the matter, but simply to call attention to a very careful and satisfactory presentation that was lately made of it, at a meeting of the Medical Society of the City of Albany, by Dr. F. C. Curtis. Dr. Curtis's association with the work of the State Board of Health has led him to make the subject more of a study than perhaps it would have been practicable for him to do in the capacity of a practitioner simply.

On the occasion in question Dr. Curtis first alluded to some of the generalities of preventive medicine, and then proceeded to discuss the causes, and the consequent means of prevention, of small-pox, scarlet fever, diphtheria, pulmonary consumption, and typhoid fever. Much interest attaches to his remarks under each of these heads, but, as we have not space to allude to more than one of the afflictions mentioned with any approach to the degree of fullness warranted by the character of what was said, we must dismiss the others with the simple note that Dr. Curtis gave unreserved expression to his belief in the contagiousness of diphtheria, an attribute of the disease which some investigators are quite positive in denying.

It is of Dr. Curtis's remarks on the causes of consumption that we shall try to give a tolerably full summary, as the subject is one about which a good deal of uncertainty is felt in the profession at present. This unsettled state of opinion Dr. Curtis contrasted with the satisfaction with which Louis's conclusions were accepted some years ago. He thought it safe to say that the facts were not all in yet, and that, until they were, it was just as well to maintain an attitude of doubt with regard to the diathesis theory, the inflammation theory, and the specific-germ theory. Coinciding in a general way with Dr. Bowditch's opinion that most cases of consumption arose from local causes—"damp grounds, wet cellars, and sloughs and undrained premises, as well as want of sunlight and good food"—Dr. Curtis would add to these the inhalation of air contaminated with sewer-gas and decomposing organic matter. Even granting that there was a specific germ, it was considered certain that under the influence of these factors the disease flourished most readily, and a specific germ could not, therefore, be taken as its only cause. There were other environments, favoring lowered vitality, which operated in like manner. An interesting statement was quoted from the "Popular Science Monthly," to the effect that among animals in the wild state consumption was much more prevalent than among those in captivity, the writer attributing the fact to exposure and to the impossibility of the beasts' escaping in their lairs from the effects of violent storms. The danger to a delicate person, inheriting pulmonary weakness, of contracting the disease was much enhanced, Dr. Curtis continued, by the presence of air contaminated from a sewer.

In looking to the proper condition of a house in which a consumptive was to spend the winter, he would look to the drains and the cleanliness of the cellar and the living-rooms before he would consider dampness and want of sunlight, as suggested by Dr. Bowditch. In so far as these unhygienic surroundings admitted of remedy, consumption was preventable.

NEUROLOGICAL WORK IN AMERICA.

Neurology and psychiatry must undoubtedly be classed among the special departments of medicine in which the best work has been done in this country of late years. The New York Neurological Society has probably been one of the most active agencies in promoting this state of things, including as it does in its membership a number of gentlemen whose individual contributions have aided materially in bringing the study of nervous diseases to its present promising condition. The influence of the American Neurological Association, too, has been plainly felt in the same direction, notwithstanding the fact of its meetings being held but once a year.

The American literature of the subject has also been of great assistance in furthering the advance of neurology. The number of treatises and monographs that have appeared among us within a few years past and their creditable character have been remarkable. The works of Dr. Hammond, Dr. Hamilton, Dr. Mitchell, and Dr. Spitzka are such as must command attention wherever neurology is studied. The periodical literature of the specialty, too, is of a most substantial and gratifying character. It is certainly not a little remarkable that four great quarterly journals of neurology and psychiatry should be so well maintained as they are. The veteran "American Journal of Insanity," although its scope is limited, as its title implies, to one of the divisions of neurology, is a publication which must be valued chiefly as freeing our lunatic asylums from the reproach of doing nothing for the advancement of medical science commensurate with the field they afford for investigation. The "Journal of Nervous and Mental Disease" naturally suggests itself next, in the order of seniority. Its high character ever since its establishment, a number of years ago, is so well known to the profession that little more need be said of it than that its
present editor, Dr. Morton, has amply demonstrated the practicality of sustaining and heightening its excellence.

The "Alienist and Neurologist" is another publication of which the success seems now to be assured, as its merit has been obvious from its start. The editor, Dr. Hughes, of St. Louis, had unusual difficulties to contend with in establishing his journal, mainly in the form of ungenerous criticism at the outset. We remember an ill-natured remark made by a writer in one of the journals, in the course of a notice of the first number, to the effect that the appearance of the second number was doubtful. Nevertheless, the "Alienist and Neurologist" has now been published regularly for several years, and the quality of its matter has been such that we must congratulate Dr. Hughes on the successful accomplishment of his task.

The "American Journal of Neurology and Psychiatry," edited by Dr. McBride and Dr. Spitzka, although the youngest of the four quarters to which reference has been made, succeeded in its first number in winning the respect of the profession, and it has gone on steadily increasing its influence. It is remarkable, in particular, for the critical ability displayed in its abstracts, but in all its departments it shows a degree of worth that makes it a solid addition to the literature of the branches with which it deals.

With these facilities, it seems not too much to hope for, that American study in neurology and psychiatry may result, within the next few years, in many substantial advances.

MINOR PARAGRAPHS.

THE PRESIDENT'S MESSAGE.

This document refers to some matters of interest from a medical point of view. One of them is trichinosis. After noting the repeal of French legislation prohibiting the importation of "hog products" from the United States, and remarking that the repeal is owing in great measure to the growing conviction in France that the prohibition was not demanded by any real danger to health, the President adds that Germany still continues to prohibit the importation of American pork, and that the Imperial Government declined his invitation to send representatives to this country to inquire into the alleged dangerous qualities of our pork. Nevertheless, an American commission has been appointed by the President to investigate the matter, in order, as the message states, "that the exact facts should be ascertained and promulgated." Some such action as this ought to have been taken long ago, and there can be little doubt that it would have contributed more than anything else to disabuse Europeans of any erroneous ideas they may have entertained as to the prevalence of trichinosis in the United States.

THE SANITARY CONDITION OF THE PUBLIC SCHOOLS.

Attention having lately been called to the wretched sanitary condition of some of the public schools of New York, an inspection has been made under the direction of the Board of Health, and on Tuesday the Sanitary Superintendent made a report to the board. Out of courtesy to the Board of Education, it is said, the president of the Board of Health refuses to make known the matter of the report. This action we can not but regard as unwise. It is the right of every citizen to know whether or not the public schools are in such a state as to endanger the pupils' health. Moreover, on general principles, it is better that the community should know the worst about such a matter, and without delay. Otherwise, the imagination is sure to magnify whatever there may be wrong. Surely these considerations are of more consequence than the requirements of courtesy between the two boards.

A MARINE HOSPITAL FOR NEW YORK.

It is getting to be more and more imperative that New York, the most considerable port of the country, should have a permanent marine hospital. Various temporary devices have been resorted to for many years past to provide hospital treatment for seamen entering the port, the last one being a two years' lease of the Seamen's Retreat, on Staten Island. Surgeon-General Hamilton considers this property the most suitable for the purpose of any that is to be had in the neighborhood of New York, and advises its purchase by the Government—a recommendation in which the Secretary of the Treasury concurs. It is certainly to be hoped that Congress will take action in the matter without delay.

MEDICAL ATTENDANCE ON JURYMEN.

Having provided the most approved rules for insuring the selection of jurymen of phenomenal stupidity, the law takes every precaution against their enlightenment, even by accident. So dear is this way of doing things to the legal mind that a judge's ire was lately roused in Philadelphia by the fact that a physician was called, without permission from the bench, to attend a sick jurymen. Conversation actually took place between the doctor and the patient, which, of course, must have impeded the course of justice!

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending December 4, 1883:

The Quarantine on the Mexican Frontier was raised on the 15th of November, and Surgeon General reports to the Surgeon-General of the Marine-Hospital Service, from Brownsville, Texas, that for fifteen days before that date the quarantine had been merely one of observation, yellow fever having ceased to be epidemic.

The Quarantine of Cattle.—In his annual message to Congress, the President says: "The appropriations, under which this department has established regulations for the quarantine of imported neat-cattle, are limited in their use to the prevention of the disease known as pleuro-pneumonia, or hog plague. Quarantine stations have been established for the ports of Portland, Me., Boston, New York city, and Baltimore. Suitable accommodations in sheds and yards have been provided for about 215 full-grown cattle at Portland, 700 at Boston, 450 at New York, and 550 at Baltimore. "The importations for the current year have been much larger than were expected from the importations of former years. More than 1,100 head were at one time quarantined at the port of Boston, and the importations at Baltimore have
been about 900 head, which exceed the importations of the previous six years combined. It is believed that the accommodations at the ports named are sufficient for any demand that is likely to occur during the next year.

"It is deemed essential to the protection of our herds and flocks from infection with the 'foot and mouth' disease, that authority be conferred upon the department to enforce a quarantine against sheep, swine, and goats also, as this disease is as liable to be communicated by them as by cattle. There is no law authorizing the quarantining of any animals except cattle. In one case, at least, the foot and mouth disease was brought in, but, the quarantine system detecting it, its spread was effectually prevented.

"It is believed that the knowledge that our Government is enforcing a rigid quarantine, to prevent the importation of contagious diseases from abroad, is already exercising a salutary effect upon public opinion in Great Britain. Perseverance in it is likely to induce Great Britain to rescind her order for immediate slaughter of cattle exported thither from the United States, which is a hinderance to our exporters.

"The efforts of the Cattle Commission during the past year have been mainly directed toward perfecting the details of our quarantine system and ascertaining, as far as possible, the precise localities in which pleuro-pneumonia has existed, and enlisting the co-operation of the several State authorities in preventive measures. Under existing laws this is a task. It is difficult for one State to effectually rid its borders of this disease so long as the transportation of cattle from another State, infected, to any place at will is permitted.

"It is advised by the Cattle Commission, one of whom has investigated the subject in Great Britain during the past summer, that provision be made for the previous domestic inspection of cattle exported from the United States to that country, and that proper regulations be provided for the kind and healthful accommodation of them on their voyage. It would be well for that inspection to be made in co-operation by officers of our Government and agents of the British Government, and at the port of departure just before shipment. If Great Britain will join in this, a certificate of health from such a board will give confidence abroad, and tend to a profitable solution of pending difficulties. Legislation for this purpose may be deemed necessary. A detailed report of the work of the Cattle Commission will be submitted to Congress early in the session."

**Conjoined Action by State Boards of Health.**—A meeting of representatives of State boards was held at Detroit during the recent meeting of the American Public Health Association, at which it was decided to call a meeting of the secretaries or other representatives of all State boards of health, in Washington, during May, 1884, for purposes of conference, and with the view of organizing a section devoted to State board work in the present association, or the formation of a permanent separate organization specially adapted to the needs of State boards of health. Dr. Henry B. Baker, of Michigan, and Dr. J. N. McCormack, of Kentucky, were appointed a committee to confer with and secure the co-operation of all the State boards in fulfilling the object of the meeting, and Dr. C. W. Chamberlain, of Connecticut, Dr. J. E. Reeves, of West Virginia, and Dr. Stephen Smith, of New York, were appointed a committee on organization, to report at the meeting in May. The American Medical Association meets in Washington in May; and another reason for holding the meeting in Washington is said to be that the representatives of the State boards may also have an opportunity of conferring with the senators and representatives in Congress, from their respective States, in regard to national sanitary legislation.

**The American Public Health Association.**—In the report of the recent annual meeting, given in our last issue, it was erroneously stated that Dr. William Brodie was the treasurer. Dr. Brodie informs us that Dr. J. Berrien Lindsley really held the office.

"The "Christian Healer."—This Brooklyn ebarlanan, Francis W. Monk by name, has been sued for a sum due for services by his "secretary," and the jury has found for the plaintiff in the sum of $300.

**Proceedings of Societies.**

**Medical Society of the County of New York.**

An adjourned meeting was held November 25, 1883, Dr. David Webster, President, in the chair.

The Report of the Committee on Hygiene, which consisted of four parts, was read by the Secretary, Dr. W. M. Carpenter.

The first part, by Dr. E. G. Janeway, related to the work of the Board of Health in preventing the spread of contagious diseases. Statutes were given of the mortality from typhoid, typhus, and scarlet fevers, measles, small-pox, and other contagious diseases, for the past quarter of a century, going to show that by the efforts of the Health Board the percentage had been considerably lessened during the latter part of the period. The work of the vaccinating corps was specially worthy of commendation and support.

The second part, by Dr. O. D. Pomeroy, referred to the influence of draughts of air, cold, sea-bathing, cold water, concussion, noise, manometers and discordant sounds, blows, pulling on the arieles, sunstroke, etc., in the production of ear diseases.

The third part, by Dr. Stephen Smith, referred to the injurious influence of sewer-gas, and called attention to the great amount escaping from the "man-holes" in the streets. The method in use was practically the conducting of the sewage along the open streets, and it so filled the atmosphere with gases that in damp weather it was necessary to close the windows of our dwellings to shut out the odor. The only effectual way of ventilating sewers was by conducting the gases into the upper atmosphere, on the principle of aspiration.

The fourth part, by Dr. S. O. Van der Poel, pointed out the objectionable features of high houses from a hygienic point of view. They were particularly liable to aid in the spread of contagious diseases through the ventilating shafts and through the pipes, and by not allowing of isolation. They also cut off sunshine from the street and from the houses adjoining or opposite, as well as from the lower stories of the same building. The upper floors could not be reached by the Fire Department.

The retiring president, Dr. David Webster, then read his address, after which the regular meeting was called to order by the new president, Dr. S. O. Van der Poel.

**Cerebral Exhaustion.**—Dr. J. Leonard Corning read a paper in which he spoke of cerebral exhaustion as a proto-phasmatic disease, giving rise to certain morbid mental phenomena, such as restlessness during the day, wakefulness at night, pains at the vertex and above the ciliary arches, derangement of memory, morbid feelings, desires, and appetites, volitional impairment, etc. There were often certain vasomotor disturbances. As to the causation, Dr. Corning referred to the sharp divisions of labor of modern life, requiring undue concentration of thought and action and extreme mental effort,
accompanied by the exhaustion of sexual indulgence and other evil habits. He regarded the essential pathology as one of inefficient nutrition of nerve-cells. The object of treatment was to replenish the exhausted nerve elements by rest, sedatives, and nourishment. There were no specifics. Rest was to be obtained by an increased amount of sleep, even to fifteen hours out of the twenty-four, and by bromides, but only as a temporary expedient. Tonics might be of service, among others the fluid extract of coca. The most difficult cases to treat were those in which there was dyspepsia. During waking hours the patient should, if possible, be engaged in some light occupation, in amusements, or labor which required but little mental effort.

Dr. L. Putzel opened the discussion. There were several points in the paper with which he could not agree. First, the author spoke of circulatory disturbances in cerebral exhaustion. This was a favorite doctrine with some, but he had failed to find the proof of it. For instance, a patient went to certain specialists, who stated that he was suffering from cerebral hyperemia. He went to another, equally noted in his specialty, who said that he was suffering from cerebral anemia. Dr. Putzel had been unable, post mortem, to verify the diagnosis of cerebral hyperemia or anemia in cases in which these conditions had been supposed to be present. Nor had it been established with the ophthalmoscope. Again, with regard to the use of bromide of sodium, a large dose might abate the symptoms for a while, but he had failed to see a case in which its continued use had not aggravated the symptoms. He regarded these cases as due to one of three causes: First, hereditary tendency to nervous disease, manifested differently in different individuals. Second, worry. He doubted whether work, or even over-work, would alone produce cerebral anemia, unless worry was added. Third, anemia. Besides rest, tonic treatment was important, and he had produced the greatest benefit with arsenic. He had failed with phosphorus.

Dr. David Webster said that he had been unable to persuade himself that patients suffering from cerebral exhaustion presented any peculiar appearance of the retina. He would suggest that, instead of placing the patient in a dark room during the hours of sleep, he should wear something over the eyes to exclude the light, and occupy a chamber in which the sun's rays could enter.

Dr. D. B. St. John Roosa had not been able to discover anything peculiar in the circulation of the retina in cerebral anemia. He thought that, if it existed, it would be more likely to be manifested in the lateral vessels of the optic papilla.

Dr. A. Jacob spoke of the subject from the point of view of a general practitioner, and said that cerebral exhaustion was not very well understood, perhaps because the brain itself was not yet very well understood. The cerebral circulation was affected largely by the condition of the other organs of the body, and its inefficiency might be due to disease of those organs. The treatment, of course, would depend upon the circumstances attending the individual case. Often it had to be directed to the heart, to the lungs, or other organs, rather than to the brain itself. But cerebral exhaustion might result from mental over-work alone. He did not refer to actual disease of the brain, as this was not mentioned by the author. It had sometimes happened, however, that we treated symptoms supposed only to be functional, when they were afterward found to be due to an actual lesion. He instanced polio-myelitis. Julius Althaus, of London, professed to cure every case of brain exhaustion by a few applications of the galvanic current. While this was a beneficial agent, Dr. Jacob said that he could not accomplish such results with it in so short a time. So far as the condition of the retinal vessels was concerned, he did not think that it was any more important as an indication of cerebral anemia or hyperemia than the condition of the blood-vessels of the neck, nor did he think the post-mortem condition would indicate whether anemia or hyperemia had been present during life. He agreed with Dr. Putzel, that there was no better nerve than arsenic. He had employed it for more than twenty years, and his opinion with regard to its efficacy had grown more and more favorable. It should be given in small doses and for some time. Where the heart was also at fault, digitalis could be given with advantage.

Dr. Andrew H. Smith had often been struck by the faulty distribution of the blood in cases of cerebral exhaustion; one moment the hands were warm and the next cold, and so of the feet and other parts. Special attention should be given in such cases to equalizing the circulation, and digitalis, among other drugs, had proved of benefit.

Dr. E. C. Harwood had found a change of climate do more good than drugs, and mentioned Switzerland and Vermont.

NEW YORK SURGICAL SOCIETY.
Meeting of November 13, 1883.

(Concluded from page 612.)

EXCISION OF THE WRIST JOINT.—Dr. H. B. Sands presented a patient upon whom he had recently performed excision of the wrist joint. He was a Swiss, forty-three years of age, and a waiter by occupation, who came under Dr. Sands's notice in the early part of last summer, having suffered for nearly a year with symptoms of strumous arthritis of the wrist, the disease having gone on to softening and destruction of the joint, without the formation of abscess. He was treated by immobilizing the joint, but without benefit. The wrist being considerably swollen, and very painful and tender, Dr. Sands decided to perform excision, which he did on the 31st of July, according to von Langenbeck's method, by making a single incision upon the dorsum of the hand and wrist. It was found that the disease involved a great extent of the synovial membrane, which had to be almost entirely cut away. The ulna and radius were separated, so that they could be moved upon each other with crepitus, and before the operation the bones were softened, the first row was removed by ordinary dissection, and the other bones were removed with a sharp spoon, the trapezium, however, and also the pisiform bone being left. The extremities of the ulna and radius were removed, and the bases of all the metacarpal bones except that of the thumb. A bone drain was inserted, pat dressing applied, and the arm was suspended. When the first dressing was removed, at the end of twenty-three days, the deep part of the wound was found entirely closed, and there remained only a superficial ulcer, which closed at the end of a few weeks. During the operation the radial artery was divided, but no harm came from the accident. The hand was now beginning to become useful, and the patient had the power of extension and flexion of the fingers to a considerable extent. He could flex the first phalanges with the metacarpal bones at nearly a right angle. Apposition of the index finger with the thumb was easy, the extension of the latter being limited, in consequence of adhesion of the long extensor tendon to its sheath. The man was free from pain, and was able to move his hand and to grasp objects with considerable firmness. Passive motion was resorted to after removal of the dressing, and had been kept up steadily since. The operation was tedious, but Dr. Sands believed that von Langenbeck's method of excision would be found preferable to that recommended by Lister, in which lateral incisions were practised.

Dr. Svinson remarked that he performed excision of the wrist last summer by the same incision, and found, as Dr. Sands
had mentioned, that the removal of the bones was very easily effected.

Dr. Sands said he omitted to state that the power of the hand was very much increased when circular compression was made around the wrist.

Anœmous AMAnatomy of the FACE and Orbit; Electrolysis; Ligation of the Common Carotid Artery.—The President related the case of a patient whom he saw first with Dr. Danvinville, who had kindly furnished the following history:

Emilio C., aged forty-three, a widow, a native of France, was born with a nemus on the right cheek, near the eye, which, although quite large, did not seem to grow or pulsate until after her first confinement, fifteen years ago. Then it began to grow steadily, extending toward the lip, but giving her no pain.

Seven years ago a Dr. Goodridge, or Goodrich (the patient remembers neither the name nor the address of the doctor), probably tied the right superior coronary artery, so far as can be made out from her vague description. Shortly after the operation, whatever it was, the anœmous began to extend upward toward the eye. She did nothing for it, as it gave her no pain, until some time in January, 1884, when, having accidentally struck her head against a bed-post, the tumor began to pain her and to increase in size.

On February 7, 1884, she came to the French Hospital for treatment. At the time of her admission her condition was as follows: A tumor extended from the orbit and lid to the lip, elevating the skin to the extent of two inches or more, pulsations being very strong and easily seen from a considerable distance. All the blood-vessels on that side of the face were enlarged. The mucous membrane of the mouth and gums was so vascular that it bled on the slightest provocation. She complained of a sense of fullness and throbbing in the eye and lip, and said that her vision had never been so good with that eye as with the other. On introducing the finger into the mouth, the pulsations were felt to be very strong and violent.

On February 17, Dr. Charles Bliss, of No. 235 West Fifty-first Street, performed electrolysis by means of a zinc-carbon battery. Eight cells were used, several needles being thrust in various places. The application lasted twenty or twenty-five minutes. This operation was followed by quite an extensive slough at the upper part of the cheek, the wound healing by granulations and leaving a crucial cicatrix. No hemorrhage ever took place during or after this operation. The pulsations were entirely suppressed where the sloughing occurred, and for some little distance around it, but nowhere else. The other parts of the tumor began to increase very much in size, the lower lid and the upper lip being very much swollen and throbbing violently, thus showing that the electrolysis was followed by beneficial results only where it produced sloughing, as stated above.

On April 21st, by the advice of Dr. F. H. Hamilton and Dr. T. M. Markoe, the right common carotid artery was tied above the omo-hyoid, the gut ligature being employed. Ether was administered. Only dry cotton was used as a dressing. Union by first intention occurred, the ligature being absorbed. No bad symptoms followed the operation, except a pain in the right arm and around the clavicle, which prevented her from raising her hand to her head for the purpose of combing her hair with the hand. After the operation, began to fall off profusely. Immedi-

ately after the operation all throbbing ceased in the tumor, except at the inner canthus near the nasal liga, where a slight pulsation could be detected by the finger; but the improvement was steady and progressive, as could be judged from the diminished size of the face, the comparatively free motion of the lower lid, and the feelings of the patient in general.

On June 5th she was discharged from the hospital. Although the pain in the right arm had very much diminished, she still had some—which was enough to impede the motions of the limb. Pulsations in lid and lip suppressed, but quite perceptible at the inner canthus.

September 4th: She called to see me to-day. No pulsations are perceptible, except at the inner canthus. The angular artery seems to be enlarged. The pain in the right arm is entirely gone. She thinks her vision on that side is very much improved. Her hair has ceased falling off. She says that, for the first time in a number of years, she can chew on that side of her mouth, and can brush her teeth without making the gums bleed. The cicatrix on the neck is very firm, slightly painful on pressure or when the weather is about to change. The cicatrix on the face, where electrolysis was performed, is hardly perceptible. She says she feels strong and has not been so well in years. In fact, the benefit resulting from the operation is greater than usual, and her present condition is as satisfactory as could be desired.

Resumé in Carbonic-Oxide Poisoning.—Dr. William S. Halsted read a paper with this title. [See p. 625.]

Dr. R. F. Wein remarked that last spring his attention was called to the frequency of coal-gas poisoning during the past few years, and also to the fact that most of the cases were due to gas made by the water process, in which carbonic-oxide existed in the proportion of about twenty-five to thirty per cent. In the gas made after the old method, it existed in the proportion of only two to six per cent. The danger, therefore, from leakage, unburnt gas, etc., in the use of water-gas, was apparently very great, and should be known more generally than it now was. Coal or naphtha-gas was much safer.

Tsal, IVREATION, RUPTURE OF THE Tube AT THE END OF THE Second MonTH; INTERNAL HERNOMA; ABDOMINAL Section; Ligation of the Tube: Death in Forty-seven Hours from Shock.—Dr. Charles K. Breidens presented a specimen accompanied by the following history: Mrs. K. L. K., aged twenty-eight, a short, stout brunette, measuring five feet and less than one inch, and weighing one hundred and fifty-five pounds, is the mother of two children, one three years, the other thirteen months old. She has always enjoyed good health. Her last normal menstruation occurred on the tenth day of August, 1883. Two months subsequently, on the tenth day of October, she had a flow of clotted blood accompanied by pain of an intermittent character. On the sixteenth day of the same month, while out walking, she was taken with sudden severe pain, and was obliged to sit down for some minutes. The pain continued with diminished severity until and after she reached home. When I saw her she was suffering considerably. The pain was pelvic, and did not appear to be more acute on one side than on the other; it was continuous, but aggravated at uncertain intervals by paroxysms of increased severity. She says that when the pain attacked her in the street she felt something flow from her vagina, but, on examining her Fen., found it only soiled with a little mucus. She complained of being unable to urinate. There was no increase of temperature, no acceleration of pulse or respiration. On making an investigation, I found the os low and slightly displaced forward. It was soft, and dilated sufficiently to admit the first phalanx of the index-finger. The body of the uterus was exquisitely sensitive and enlarged. Tho the physical conditions of retroversion were not present, I thought that the inability to urinate might be occasioned by some mechanical impediment. I emptied her bladder, and, placing her in the knee-elbow position, found that, on opening the vulva, the uterus receded and there was nothing at all to be felt in the cul-de-sac. Rest and a few doses of chlorodyne sufficed for treatment, and in a few days she was well.

In the afternoon of the 29th she was again attacked with pain, and, although there was no flow, I suspected that abortion was imminent, and prescribed an anodyne and rest. I received a second, urgent message to see her at 7 p.m., and I found her suffering with symptoms of internal hemorrhage. She exclaimed that she was dying; her extremities were cool, her face was pallid, and I could detect no radial pulse. I had no hesitation in expressing the opinion that the case was one of tubal pregnancy, and that rupture had taken place; I explained the dangerous character of the condition to her husband, and
the probability that prompt action would have to be taken, and I requested counsel. Dr. H. F. Walker saw the case with me before nine o'clock, and suggested that we should call in Professor T. G. Thomas, who saw the patient at half-past nine. There was no division of opinion; all were agreed that an abdominal section and the institution of such means as would secure against the further escape of blood were the only ones calculated to afford even the slightest chance of recovery. The consent of the patient and her friends being obtained, the only delay was occasioned by the insistence on their part that she should receive the sacrament before the operation.

I was ably assisted by my friends Dr. Grsster, Dr. Walker, and Dr. Scharlan, and it affords me great pleasure to testify to the kindness and promptness with which they responded to my call for assistance under very trying circumstances. Ether was administered by Dr. Scharlan, and very little indeed was used. The corpulence of the patient made it necessary to make a long incision, reaching from the umbilicus to the pubes. Her collapsed condition rendered this almost a bloodless proceeding. When the peritoneum was exposed, a small incision was first made, which gave exit to a large amount of fluid blood. The incision was then enlarged sufficiently to admit the hand, and at least a pint of blood-clot was scooped out as rapidly as possible. The uterus was then drawn up as far as its connections would permit, and the cause of trouble was at once apparent. Part of an ovum, one inch and a quarter in diameter, was found protruding from a rent in the left Fallopian tube close to its uterine extremity. The broad ligament was lifted as much as possible, and a probe, armed with a double stout plaited-silk ligature, was passed through it as low down as could be done, and the ends were firmly secured above the free border. In these manipulations the ovum was forced from its bed in the ovindic, and was removed entire. The haemorrhage appeared to be entirely controlled, the ligatures were cut short, and the toilet was completed by thorough cleansing of the cavity. The wound was then closed by silvery-wire sutures. No time was lost in completing the dressing, but the patient was removed at once to bed, surrounded with blankets and hot bottles. Her head was enveloped in a warm woolen shawl, a small hypo-
dermic of morphia was administered, and brandy was used sub-
cutaneously. It was not, however, until after midnight that an occasional flicker could be felt in the pulse at the wrist. Vomiting, which occurred, was treated by frequent sips of hot water. Nutrient and stimulant enemas were used all through the night. On the morning of the 30th her appearance was much improved. She was inclined to talk, was even cheerful, and expressed herself as entirely free from pain; she only complained of the vomiting; but, notwithstanding these favorable signs, her pulse could scarcely be felt, much less counted; at times it could not be distinguished at all. The temperature was 101°, the respiration 56. At 10 a.m. her pulse could be counted, and it was 126; after this it improved for twenty-four hours, averaging 130, the temperature for the same period being 101° to 102°. In spite of the most assiduous stimulation, the circulation could not be maintained; she began to sink on the afternoon of the 31st, and died at 9.30, forty-seven hours after the operation.

Section Caecalis.—October 31st, 11 a.m.—Abdomen only moderately distended. Abdominal wound aglutinated, but easily separated. Omentum adherent to the peritoneal surface in the neighborhood of the line of incision. No general diffuse peritonitis. About two ounces of odorless bloody fluid in the cavity of the pelvis. The left broad ligament adherent to the anterior wall of the rectum. Uterus enlarged to nearly twice its normal dimensions. At the junction of the left ovindic with the uterus, and encroaching upon the cornu itself, was an ovoid swelling about one inch in diameter, darker than the surround-
ing structures, of a mottled, violaceous maroon color. Near the junction of the posterior wall of the duct with this swelling was a ragged opening half an inch in length, and leading into a cavity formed mainly out of that portion of the duct that traverses the uterine wall, so that the specimen might be said to represent the variety known as interstitial, or, more correctly, tubo-interstitial gestation. On incising that portion of the cavity that was developed at the expense of the uterine textures, it was found filled with adherent coagulum. The cavity of the uterus was not lined with decidua, and the uterine opening of the oviduct was impervious. Outside the rent were found the ligatures applied during life, and which had effectually controlled the haemorrhage.

Remarks.—About twenty years ago a surgeon of this city, the late Dr. Stephen Rogers, was a vigorous advocate for the performance of laparotomy in cases of internal haemorrhage due to rupture of the oviduct; but the profession was not at that time prepared to accept the proposition. The great advances that have been made in abdominal surgery since then have paved the way, and, although I am not aware that the operation has been performed, I can state advisedly that the matter has been much debated, and that the views of Dr. Rogers are now generally approved. Grailly Hewitt says, in the last edition of his work on the "Pathology, Diagnosis, and Treatment of the Diseases of Women": "In cases of Fallopian pregnancy, if it were possible to make an exact diagnosis of these cases of rup-
ture and haemorrhage during life, it would undoubtedly be bet-
ter to open the abdomen and endeavor to secure the bleeding vessels than to allow the patient to die of haemorrhage. No operation of the kind has ever been attempted, but the subject has formed matter of discussion on more than one occasion at the meetings of the Obstetrical Society of London." Dr. Lawson Tait, in his recent book "On the Diseases of the Ovaries," says: "I have very little doubt, however, that many of these cases would be saved by prompt action. The difficulty is, of course, in the diagnosis, some certainty of which is requisite before an abdominal section can be performed. I have twice been on the point of performing abdominal section on account of suspected rupture of a Fallopian tube, and have been prevented by scruples as to the correctness of the diagnosis. In both cases post-mortem abdominal section showed that the suspi-
cion was correct, and I believe both of these patients might have been saved."

Other authorities might be quoted indorsing the opinions thus expressed, but I think these will suffice to show the general conclusions of those most familiar with the subject.

In the case that forms the basis of this communication the subject of transfusion was entertained and rejected. Pre-
vious to the operation I could only conceive that it would be harmful where we had to deal with concealed haemorrhage, and there are such doubts as to its precise location and charac-
ter as may render it questionable whether we are warranted in adding the shock of an operation to that already existing. The issue of the case will depend upon the success with which we can keep the circulation at a minimum consistent with life. If we resort to means which raise arterial tension, we shall inter-
fer with those conservative processes which we must utilize with more or less success in the application of haemostatics, and cer-
tainly cause further leakage from partially occluded vessels. In this case, after the blood-supply was cut off by the application of ligatures, I had faith in the natural robustness of the patient, and, though she hovered between life and death for twenty-
four hours, the condition of the pulse after that time, and up to within a few hours of death, justified the confidence I had placed in those resources. The heart failure, which occurred more than forty hours after the bleeding was arrested, I at-
treated to shock, which I did not think could be beneficially influenced by transfusion, and, consequently, did not feel warranted in resorting to a means that I certainly do not regard as safe from danger.

**Ankylosis of the Knee in a Flexed Position; Resection; Wiring of the Bones together in a Straight Position; Gangrene of the Leg and Foot; Amputation of the Thigh; Death.**—Dr. A. C. Post presented a specimen with the following history: A. P., a mulatto, aged thirty-eight. His left knee was ankylosed in a flexed position at an angle of sixty degrees. At the age of eleven years he cut his knee with an axe, and the ankylosis was the result of the inflammation which followed the injury. July 5, 1883, I operated on him by making a transverse incision over the greatest convexity of the knee, the incision dividing the integument over the anterior and lateral parts to the extent of three quarters of the circumference of the limb. Several small arteries were cut and tied. I then, with a saw, removed a large wedge-shaped segment of the bone, and afterward several smaller segments. I also divided the tendons of the biceps, semitendinosus, semimembranosus, gracilis, and sartorius, after which I was able to bring the bony surfaces in contact, in an extended position of the limb. Considerable resistance was offered by the popliteal nerve, which finally yielded without rupture. I then drilled four holes obliquely through each segment of the bone, through which I inserted flexible iron wires, which I twisted so as to keep the bones in position. After this I applied an iron splint along the posterior surface of the limb, and one on each lateral surface. The lateral splints were each bent at four right angles, so as to leave an open space on each side of the knee. Plaster-of-Paris bandages were then applied over the thigh and leg, holding the splints in position, but leaving a space of more than six inches over the knee uncovered, so as to give free access to the wound. The wound was washed with carbolic acid, 1 to 40; and the integuments were brought together with sutures, except at the posterior part, where a large open space was left for drainage. The parts about the wound were then covered with lint wet with carbolic acid, 1 to 40. The operation was completed at about 7 P.M. At about 11 P.M. I was summoned to the patient on account of hemorrhage. I found that there had been considerable oozing of venous blood. I had the limb elevated, applied compresses over the wound, secured by a roller bandage, and suspended the limb to the ceiling, with the foot elevated about fifteen inches above the bed.

**July 6th.**—There has been no return of bleeding. The patient has been much more comfortable since the suspension of the limb. As his circulation was very languid, and he had been accustomed to the very free use of alcoholic drinks, I directed him to drink three or four glasses of weak tea and milk paneer. 

**7th.**—He has had frequent vomiting, and has scarcely retained anything in his stomach. A sinapism was directed to be applied over the epigastrium, and a sample of colonel was administered, after which porter and lime-water were directed to be given, a half-hour of each hour. Reetinal alimentation was ordered, with stimulants.

8th.—Vomiting has nearly ceased. His pulse has a little more force, but is still feeble. The integument about the head has a livid appearance, but has not lost its sensibility. The lower flap of integument in front of the knee is quite livid, but the upper flap is of a good color.

9th.—The leg and foot are decidedly gangrenous. I amputated the thigh, about 11 A.M., above where the bone had been divided in the resection, leaving a large anterior flap.

10th.—The patient has not rallied well since amputation. The pulse is feeble and the surface cold. He continued to sink, and died in the afternoon. He had taken stimulants freely, but very little food.

The fatal result in this case was largely to be attributed to the previous habits of the patient.

**Tubercular Orchitis.**—Dr. A. G. Gerster presented a specimen with the following history: It was a testicle removed from a man forty-one years of age, and was the seat of tubercular orchitis. The diagnosis was made before any fistula formed, from the fact that an acute orchitis, which resulted from injury, had never completely subsided. The patient, two or three weeks before Dr. Gerster saw him, had chills and night sweats, and the spermatic cord became infiltrated and inured close up to the internal ring. Castration was performed, and the patient did well. When the tunica vaginalis was opened, the tissues presented an appearance similar to that seen in a fungous condition of the joints, but the center of the testicle contained a large tubercular focus.

**PHILADELPHIA COUNTY MEDICAL SOCIETY.**

**Meeting of November 21, 1883.**

**Further Notes on the Use of Hamamelis in the Treatment of Varicose Veins.**—Dr. J. H. Musser read the following paper: Some time ago the writer called the attention of the profession to the use of hamamelis in the treatment of varicose veins and their sequences. Since then numerous inquiries have been made of him concerning this drug, and several cases have been reported to him of its use. It has, therefore, been deemed advisable to again refer to this plan of treatment in order to instigate further investigation by the profession, so that the exact value of the drug in this disease may be determined. In the first place, to determine this question, it is important to know whether the beneficial results of the treatment of the cases previously reported were permanent or not.

The three cases noted in full in this paper have been under my observation ever since that time. The first two may be dismissed at once by saying neither of the patients has had any return of the varicose veins or of any symptoms of them. Regarding the third, who was to be present to-night, it will be remembered that, on account of the severity of his symptoms, he was unable to work for nine months prior to having taken the medicine, and for three months of that time he was treated in a hospital by rest, pressure, etc. He returned to work two months after beginning the hamamelis, and has continued at his laborious occupation ever since. In answer to a summons, he presented himself two weeks ago. He had not taken any medicine for ten months. There was no return of any one symptom of his disease, save the varicosity noted below and slight edema of the leg. The tissues, however, readily take on ulcerative action, for every time a stone fell against his leg an ulcer formed, with this difference from formerly, that it healed rapidly. On examination, two inches below the knee, on the inner aspect of the leg, a congregation of veins is found. They are not painful, returned during the past month, and have given him no trouble. The edema of the ankle is marked. There is a small healing ulcer on the right leg, which was caused by a stone falling on the leg a month ago. Both extremities are very cold, on account of which he wears heavy stockings and wooden material—articles that were unendurable one year ago. When the past sufferings of this man are compared with the comfort and usefulness of the past year, in view of the previous systematic treatment of him, it can scarcely be gainsaid that hamamelis is of value in varicose disease. The writer takes pleasure in referring to his friend, Dr. Judt, who has been familiar with the
case, past and present, and will substantiate the statements regarding him.

The subsequent experience of the writer has not been a large one, and only two patients can be referred to positively. Others were treated, but did not report for inspection after the second or third visit. Of the two, one was much benefited; the other not relieved. There is no sufficient cause for the failure of the drug in the last case. But, in order not to prevent the facts alone of a probably prepossessing observer, the statements of numerous gentlemen will be given who have made use of the drug since the article referred to was published. It is, no doubt, natural that only the favorable cases have been reported to the writer—failures not being considered worthy of notice. There are some unfavorable comments given, however, and they will be first noticed.

Thus Dr. Dulles, surgeon to the dispensary of the University Hospital, writes as follows: "I tried it in a number of cases of leg-ulcer in the dispensary, and finally abandoned its use, because I came to the conclusion that it was only of moderate value, and could in no sense be looked upon as a substitute for the ordinary surgical methods of treating these ulcers."

Rather more favorable is the testimony of Dr. Stelwagon, chief of the Skin Dispensary of the same hospital. He says: "The remedy was made use of in about fifteen cases—in patients with eczema, ulcers, or both, in whom the veins were at all enlarged. In three instances the results seemed, both to the patient and myself, favorable. In four or five cases the patients thought some benefit had ensued; I could not convince myself that such was really the fact. In the remaining cases no improvement followed its use." In all the cases the roller bandage was employed. Dr. Stelwagon says his experience is negatively favorable, and the remedy is worthy of more extended trial. Of the six cases treated by Dr. Van Harlingen, professor of skin diseases at the Polyclinic, there was one quite successful case; two patients improved very much; the remainder made but two or three visits to the dispensary.

Still more favorable is the testimony to follow. Dr. R. M. Girvin reports two cases cured—no failures. One was that of a female with varicosity of the deep veins of both legs, with swelling and induration of the limb and spots of ulceration as large as a dime. The veins were enlarged and tender; the pain was intolerable. One teaspoonful of the fluid extract of hamamelis every hour was ordered, and improvement was seen in three days; a cure in two weeks. No other treatment was used, and the patient was on her feet most of the time during the treatment.

Dr. Shelly, of Ambler, Pa., reports the following:

Female, aged forty-five, cook, varicose veins in both lower extremities of fifteen years' duration, unhealthy ulcer on outer aspect of left ankle joint of ten years' duration. Ulcer followed a hemorrhage, and never healed. Both legs edematous, the left much indurated. Eczema around the ulcer. Pains so great she had been confined to her chair or bed for one month. Treatment: hot bran baths and thin adhesive strips to left limb only; hamamelis in teaspoonful doses five times daily. Relief almost marvelous, being about the house in one week, and three months afterward the knots and distorted veins had entirely disappeared, notwithstanding the continuance of her laborious duties. The rubber stocking which she had used for years was discarded, and its use has not been resorted to.

Dr. P. G. Skillern writes that he treated

Mrs. K., aged fifty, for varicose disease of the veins of the left leg, with secondary edema, causing pain and fatigue on exercise. September 17th, ordered drachm doses of the fluid extract, and the distillate externally. October 1st she reported much relieved, and October 16th cured, experiencing no pain from the limb.

Dr. Preston, resident physician to the Presbyterian Hospital, and Dr. Cobbling, holding a similar position at St. Mary's Hospital, report cures. The former used it but once, and with success. Dr. Cobbling used it in several cases, with satisfactory results, and recalls distinctly one case, that of a middle-aged man, who took drachm doses of the preparation every two or three hours, with rapid and decided benefit.

To further illustrate the affinity this drug has for venous structures, Dr. W. E. Hughes writes that a case of phlebitis, secondary to chronic Bright's disease, was entirely and rapidly relieved by the use of this drug.

These reports ought to be of some avail to convince the most captious. It is thus seen that positive and negative results are given. The accuracy of observation can not be doubted, and hence conclusions can only be vitiated by two factors, the preparation used and the dose exhibited. It is difficult to make a numerical statement, and so it can only be said that this drug is of decided value in a certain proportion of cases of varicose disease. If an estimate were to be made of the proportion of cures and failures, without fear of exaggerating, it may be said that one fifth of all cases are cured, and that one third of the remainder are benefited. Even with this small percentage in its favor, from the inexpensiveness and simplicity of the plan, it behooves us all to try it. The testimony distinctly proves that the drug has a decided action on the veins.

The allusion to the preparation is timely. One gentleman told the writer he found the drug of no use. On inquiry, it was found the distillate—a white preparation—was used. Another reported a negative result, but used a preparation whose value is doubtful. The fluid extract is the most reliable preparation—a dark one—and that from the laboratories of Bullock & Crenshaw, or Parke, Davis & Co., the strongest, apparently. Regarding the dose, the writer feels that the one recommended in his former article is too small, and that if the amount or frequency were increased it would be valuable.

Other Use of the Drug.—In addition to the foregoing testimony, Dr. Girvin gives the notes of two cases of hematuria that were cured by the exhibition of hamamelis:

1. Mrs. P., aged forty; hematuria; for six weeks had passed blood every day; some days in large quantities. She was anemic, weak, without appetite, and rapidly failing. Test of urine showed albumin in large quantity, which Dr. Fornad decided was due to the blood. Ordered thirty-drop doses of the liquid extract every three hours. The third day the bleeding ceased, and had not returned two months after the first administration of the drug. No albumin could then be found in the urine.

2. Mr. P., aged fifty-three, was relieved promptly of the same disease. "I have used it," he says, "in a number of cases of menorrhagia, rhagia, and regard it as more certain in its effects than ergot or any other styptic in use for such conditions."

Dr. Dulles adds to his communication that he considers hamamelis a good astringent and a stomachic tonic.

In conclusion, the writer desires to express his indebtedness to the many gentlemen for the privilege of using their notes.*

* Since this paper was read, Dr. Randall, resident physician at the Philadelphia Hospital, has reported as follows: One case of varicose disease not benefited. A second case of the same, with secondary ulcers and edema, was relieved in three weeks. Treatment discontinued, a relapse followed; treatment renewed without benefit. In the third case the disease was of three years' duration, in a man, aged fifty-two. He had tried numerous remedies without benefit. The use of hamamelis and a roller bandage gave him decided relief. Finally he reports that Dr. K., aged forty-eight, a sufferer from "bleeding piles," had been cured in three weeks with drachm doses, four times daily, of the drug. (To be concluded.)
NEW YORK OBSTETRICAL SOCIETY.

A stated meeting was held October 18, 1883, Dr. C. C. Lee, President, in the chair.

VAGINAL Hysterectomy for Epithelioma of the Cervix Uteri.—Dr. Pat. F. Menkoh related a case of epithelioma of the cervix uteri in which he had removed the uterus and the ovaries by the vaginal method at Mount Sinai Hospital six days before. The specimen was shown, and, as Dr. Mandé remarked, it seemed to indicate that the diseased tissue had been thoroughly removed. Thus far, the patient had done perfectly well. It was now a question how long the drainage-tube should be left in place. It was held by a flange, and there was no leakage around it.

Dr. T. A. Emmet thought the tube would have become so encysted at the end of a week as to answer no further purpose.

[Note by Dr. Mandé, November 17th.—The tube was removed on the eighth day, the ligatures and sutures on the sixteenth, all but one ligature, which was still retained five weeks after the operation. The patient left her bed on the fourteenth day, and the house during the fourth week.]

Benjamin F. Dawson, M. D.,
Frank P. Foster, M. D., ex officio,
Committee on Publication.

A stated meeting was held November 6, 1883, Dr. W. M. Polk, President, in the chair.

Tait's Operation.—Dr. W. T. Lask presented specimens and related a case as follows: The patient was sent to the hospital by Dr. Buchanan Burr, with the message that hers was "a good case for Tait's operation." She was twenty-four years of age, had been married four years, was sterile, had previously always been well, and had menstruated regularly and without pain. Within a year past she had begun to suffer from paroxysmal pains, commencing on the left side of the pelvis and extending upward across the abdomen and down the left leg. The pains were excessively severe, came on suddenly, lasted for several hours, and then entirely disappeared; the patient would feel that she was entirely well, when another paroxysm would occur before the lapse of twenty-four hours; they usually came on at night. Dr. Lusk, on examining her, found a tumor extending across the left half of the pelvis, and having its origin behind the uterus. There seemed to be obscure fluctuation; the consistence of the tumor enabled him to exclude fibroids; the absence of tenderness made it almost absolutely certain that it was not the result of pelvic cellulitis. The diagnosis then lay between a dilated Fallopian tube and a small ovarian cyst. The fact that the tumor was firmly adherent rendered ovarian cyst doubtful; in that case adhesions rarely formed while the cyst was small. On the other hand, it seemed impossible that the Fallopian tube could have attained to the apparent dimensions of the tumor. The patient was kept in the hospital a month to make sure that the pains were not hysterical, and that the tumor was not diminishing. As no relief was afforded, however, the patient was informed of the risks of an operation, and of the possibility of failure to produce relief. She concluded to have it done. An incision two inches and a half in length was made, the finger introduced, and the tumor recognized to be a dilated Fallopian tube. The extremity lay directly behind the uterus, and was firmly adherent to that organ. The entire tube, thus bent upon itself, filled the left side of the pelvis, and was, throughout its entire extent, adherent to the pelvic floor. The adhesions were separated with difficulty with the fingers. It was necessary to increase the abdominal opening to four inches in length before the tumor could be withdrawn. The appearance was very much like that of large intestine, and its true nature was determined beyond doubt only after careful inspection. Sponges were packed into the cavity where the tumor had lain to absorb the slight amount of oozing which was taking place. A ligature was applied around the pedicle, and the tube removed. All bleeding had ceased when the abdominal wound was closed. The patient made an excellent recovery, no untoward symptom having developed; pain had since entirely disappeared. The origin of the trouble in the first place could not be explained; the patient had previously been healthy; she had never suffered from pelvic peritonitis nor cellulitis, nor had she had venereal disease. There was said to be consumption in the family. The diseased tube contained pus; the other was healthy and was not interfered with.

Dr. Lee thought Dr. Lusk was to be congratulated on his ability to make an exact diagnosis in so obscure a case, and on the result of his operation. In such cases it was sometimes impossible to make the diagnosis before the abdomen had been opened, and, in obscure cases in which patients suffered as Dr. Lusk's did, he believed we were justified in making the exploratory incision, and, finding our suspicions verified, in removing the diseased tube, this being the only means which offered the patient relief from intense suffering. He referred to a similar case in which he proposed to operate if the patient's consent could be obtained. She had first consulted a distinguished physician in Vienna, Professor Braun, who believed her symptoms to be due entirely to constriction of the cervical canal, but she had an attack of pelvic inflammation following the examination, and could not undergo treatment. On her return to this country, she consulted Dr. Lee, who recognized a tumor evidently connected with the Fallopian tube and probably with the ovary, and recommended Tait's operation. The diagnosis was confirmed by Dr. Thomas and Dr. Emmet. The tumor had since suppurated and discharged pus through the rectum.

Dr. R. Watts inquired whether the discharge of pus should not be taken as an indication of strong adhesions, and contraindicate the operation.

Dr. Lee replied that we might in any case be compelled to abandon the operation on account of the extent and firmness of the adhesions, but this could not be positively predicted from the patient's previous history. He had operated successfully in one case in which there had been repeated attacks of peritonitis, and on two occasions the abscess had discharged into the rectum. Dr. Hunter had had similar experience.

Dr. Lusk remarked that nothing could have been more adherent than this tumor to the uterus, and he would probably have abandoned the operation had he not witnessed the immunity from danger which attended the digital separation of adhesions in the hands of Mr. Tait.

In reply to a question by the President, Dr. Hunter said he agreed with the remarks made by Dr. Lee, that in such cases an abdominal incision was justifiable in order to arrive at a diagnosis. About two weeks ago he operated upon a patient who had recently returned from England, where she had been under treatment by Sir Spencer Wells for ovarian neurasthenia, Galvanism and many other remedies had been employed, but without success. The patient had been married six years, had never been pregnant, menstruation had been steadily diminishing in quantity, and, during the past six years, had been attended with intolerable pain. During the past two years the patient commenced some time before, and continued for some time after the flow, the interval of rest being but a few days. The uterus was normal and not flexed. At the first examinations the ovaries could not be felt; subsequently enlargement of one ovary was made out with tolerable certainty. At the operation the right ovary was found much enlarged and cystic; the left was...
cystic, but only slightly enlarged; both tubes were slightly diseased. The ovaries and tubes were removed. The patient was doing well; there had been scarcely any rise of temperature, and pain had disappeared. It was, of course, too early to determine the permanence of the result. Dr. Hunter had found Ferguson’s speculum useful in cleaning out the cavity with sponges on handles. He mentioned some cases in which the ovary was not found diseased, but firmly bound down by adhesions, which in itself was sufficient to account for the pain from which the patient suffered during menstruation. In two instances in which the adhesions were very firm, and required great force in breaking them up, considerable bleeding took place. One of the cases was fatal. In the other, secondary hemorrhage occurred, and the patient died. The wound was reopened, but the bleeding was too deeply situated to be arrested. To illustrate the difficulty of diagnosis, he also mentioned a case in which engravement of one ovary was diagnosed by several examiners, and at the operation the opposite one was found to be the larger.

Dr. J. Byrne gave the symptoms and physical signs in two cases similar to Dr. Lusk’s, in which he had contemplated Tait’s operation, but hesitated somewhat because of possible extensive and firm adhesions. He was glad to have this point brought out in the discussion.

The President asked whether they had had any experience with Hegar’s method in the diagnosis of these cases: viz., exploration of the posterior surface of the uterus with two fingers in the rectum, the organ being pulled down with the tenaculum in the vagina.

Dr. Byrne thought there would be great danger of bringing on inflammation by such a procedure. One patient of his newly lost her life from peritonitis brought on by manipulation during repair of the cervix.

The President said that pelvic inflammation would certainly be liable to result from Hegar’s procedure, but he thought the risk might be assumed in cases in which opening of the abdomen would otherwise be necessary for diagnostie purposes.

Ovariotomy.—Dr. B. F. Dawson presented specimens with the following histories: The first patient consulted him about two months ago, suffering from general nervous disturbance and neuralgic pains in the pelvis. The slightest pressure about the ovaries gave acute pain. The patient was subject to epilepsy, and had a seizure during the examination. Cystic degeneration of the right ovary was recognized. At the operation on the left ovary there was also found a small parovarian cyst, and this ovary was also removed. The patient made an excellent recovery, and was now sitting up.

Dr. Dawson also presented a second ovarian cyst, removed on the 24th of September. He first saw the patient a year ago, when he told her it would ultimately require removal, and he kept her under observation until symptoms called for operation. Considerable difficulty was experienced in detaching some firm adhesions at the base, but the patient made a very good recovery. The clamp was employed to secure the pedicle, on account of exceedingly large vessels making ligation seemingly injudicious. The cyst was of the dermoid variety, and contained a large mass of hair, but no bone or teeth.

A third specimen was that of an ovarian cyst of the papillomatous variety removed from a patient at the Woman’s Hospital that afternoon. The tumor was recognized to be a polycyst with considerable adhesions. The diagnosis was confirmed by Dr. Eames. About a gallon of fluid, containing odorless purulent fluid, was withdrawn from the three compartments into which the cyst was divided, and the operation was difficult and protracted on account of extensive and very firm adhesions to the intestines, uterus, and bladder, requiring the actual cautery and numerous ligatures. Of a large number of operations which the house staff had witnessed, in none had they seen firmer and more extensive adhesions. Owing to the uterine adhesions being almost inseparable, Dr. Dawson thought the only safe procedure was to apply his large clamp to the thick pedicle formed by the fundus of the uterus. The patient lost but little blood, and reacted well.

Dr. Hunter asked whether it would not have been better, finding the adhesions so extensive, not to have proceeded with the operation.

Dr. Dawson replied that the firmness of the deeper adhesions was not recognized until the upper ones had been detached, in answer to a question by Dr. Lee, as to whether it would not have been better to extirpate a portion of the uterus than to apply the clamp, he said the patient was not in condition for the operation to be protracted by such a procedure; moreover, his experience with extirpation of the uterus in one case had prejudiced him against its repetition.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A stated meeting was held November 10, 1883, Dr. B. W. McCready chairman for the evening.

Penetrhritis with Obscure Symptoms.—Dr. A. B. Ball related a case the chief interest of which was the obscurity of the symptoms. The patient was a boy, five years of age, who had recently returned from the country in perfect health. On Wednesday, the 24th of October, the child went to a lunch party, and there ate of various kinds of indigestible food. He experienced no inconvenience that afternoon, but vomited during the night. Irritability of the stomach continued the next morning, but, as the boy did not appear very sick, Dr. Ball was not sent for until afternoon, and then found him sitting up in bed, bright, and apparently not very sick; the temperature was about 100°F., and the pulse was a little above normal. A careful examination was made. Slight tenderness existed over the abdomen, but a little more marked in the right iliac fossa. No swelling nor induration could be felt at any point. In the absence of any other assignable cause, the case was believed to be one of indigestion. The child rested well during the night, and about the same condition was found to exist on the following morning; there was no more fever, and no more abdominal tenderness. Compound licorice powder was administered, but, that not having taken effect by 4 p.m., castor-oil was given, with the effect of producing five movements during the course of the evening. The next morning the child was evidently not so well; the temperature had risen a little above 101°F., the pulse was about 120, the abdomen was a little more sensitive, especially in the right iliac fossa; at the same time the tenderness in this region was by no means marked; there was not the slightest indication of any induration or swelling. The symptoms were still such as would point only to slight enteritis due to a very indigestible meal. Six beeches were applied to the right inguinal region, and drop-doses of Magendie’s solution administered every three hours. As some uneasiness was felt in regard to the case, Dr. Sands was called in consultation, and he also was puzzled as to the exact condition present. He was inclined to think, however, that, while there was some inflammation in the region of the cæcum, there was no evidence of perforation of the appendix. The next day the child’s condition was not worse; the temperature at no time went above 102°F., and the pulse ranged between 120 and 150. Monday
morning the child was much better; the temperature had fallen to 99°, the tenderness in the right iliac fossa had diminished, and the pulse was slower. The conclusion was then reached that perforation had not taken place; that the attack had probably been simply one of indigestion, and Dr. Sands thought it was unnecessary for him to see the patient again. That afternoon, however, the child was seized with repeated attacks of vomiting of a greenish liquid matter, and with symptoms of collapse. Dr. Ball arrived about two hours later, and found the extremities cold, the face pinched, the respiration almost entirely thoracic, and the child on its back with the legs drawn up—perforation into the peritoneal cavity had evidently taken place. Dr. Sands was present at about 9 p.m., at which time the temperature was 103° F., the pulse about 160; there was but little tenderness over the abdomen; the tenderness was not great, but was more general than at any previous time. The case was pronounced hopeless. The child died the next morning. The mother had at no time ceased to reproach herself with the thought that she had been the sole cause of the child's illness. Feeling confident that the death was due to perforation of the vermiform appendix, and that the indigestible meal of the Wednesday previous could have no direct connection with the causation of such an accident, Dr. Ball insisted upon an autopsy, which was granted by the family. The examination was made by Dr. Ferguson, Pathologist to St. Luke's Hospital. Upon opening the abdomen, signs of general peritonitis were found; the coils of intestine were covered with a sero-fibrinous exudation; there was no pus in the general cavity. The coils of intestine in the right iliac fossa were so glued together that it was necessary to remove them en masse. There was a small amount of pus, perhaps a tablespoonful, deep in the right iliac fossa, alongside of and to the outer side of the appendix. The appendix was unusually long and convoluted in shape; it was perfectly healthy except near the extremity, where the canal was completely blocked by a hard, stercoral calculus of the size of a large bean. No nucleus was found on section. Beyond this point the gut was gangrenous and perforated. The adhesions between the coils of intestine indicated that perforation must have taken place at the commencement of the sickness. A collection of pus had formed gradually, and on the day previous to death had penetrated into the peritoneal cavity and excited fatal peritonitis. It now seemed probable that at the time when perforation of the appendix took place only a small portion of its contents escaped, causing but slight inflammatory reaction and no appreciable induration. Dr. Ball said that he had seen fourteen cases of perityphlitis, in adults and in children, and in all the previous cases there had been no difficulty in the diagnosis after the first twenty-four or forty-eight hours. In one only—that of a girl between four and five years of age—did death occur, and in that instance there were signs from the first that general peritonitis had followed perforation. In every case dullness on percussion and an indurated mass could be felt above the brim of the pelvis within two or three days of the commencement of the symptoms. In about half of the twelve cases which ended in recovery, abscess formed and convalescence was established after a variable length of time.

Dr. R. Watts inquired whether examination per rectum had been made.

Dr. Ball replied in the negative; that the child was quite young, the symptoms did not point to the existence of inflammation outside the bowel, and it was not considered advisable to subject the patient to the inconvenience of a rectal examination. At the autopsy this point was considered, and it was regarded as doubtful whether any information would have been thus gained.

Dr. Watts said that he made the inquiry because in two cases in which the symptoms pointed to perityphlitis, but in which no tumor could be felt on external palpation, with the finger in the rectum a hard swelling was discovered in the right iliac fossa. One patient was aged twelve, the other nineteen years. Both recovered without operation.

Dr. Ball remarked that, in several of the fourteen cases mentioned, a swelling could be felt per rectum, but in each instance it was also evident on external palpation.

**Symptoms of Peritonitis Relieved by Tartarized Antimony.**—Dr. A. C. Post had been called in the evening to see a child, about two years and a half of age, whom he had been treating for an injury of the hand, and who then had symptoms of epeon. The breathing was a good deal impeded from what appeared to be laryngeal causes; no membranes, however, was visible. Dr. Post therefore believed the case to be one of catarrhal laryngitis, with spasm of the glottis. Chloroform was administered, first, to relieve spasm, and, second, to enable him to incise the gums, which had been giving a little pain. Afterward a solution of tartarized antimony—one grain to eight ounces—was ordered to be administered in teaspoonful doses every half-hour until vomiting or relief followed. The child was doing well the next morning, and no further treatment had been required.

**Cirrhotic Aneurysm of the Wrist.**—Dr. Post mentioned the case, which was that of a young man who had presented himself at his clinic on that day. The aneurysm was of the radial artery, at the radio-carpal articulation, about twenty-five millimetres in diameter and four in elevation. The tortuous course of the vessel could be distinctly traced by the pulsation. The tumor had existed for several years, was gradually increasing, and had lately caused some disability of the hand. The treatment of such cases had often proved unsatisfactory, but Dr. Post proposed to tie the artery at several points should the patient return.

**NEW YORK CLINICAL SOCIETY.**

A regular meeting was held September 28, 1883, Dr. J. H. Emerson chairman for the evening.

**Strangulated Hernia.**—Dr. Robert Abbe related the histories of two cases in which he had recently performed keotomy. The first case was in a boy of ten years. Symptoms of strangulation had existed three days when the case was first seen. Taxis was tried, and it was at first thought that entire reduction had been effected. Closer examination, however, showed a small tumor in the groin which had not gone back. The symptoms persisted, and, after waiting two days, during which time the temperature rose to 102° Fahr., he operated. Upon cutting down, he found a bubooncele of about the size of a walnut. It was found necessary to slit up the whole inguinal canal before it could be reduced. The intestine was of a purplish color, but showed no signs of gangrene. About two ounces of bloody serum were found in the sac, which was opened. Full Lister dressings were used in this case, and, without any untoward symptoms, the boy went on to a perfect recovery.

The second patient was a man of fifty-seven. Five days before coming under observation his hernia, an old one, had come down, and he was unable to reduce it. He took large doses of salts, castor-oil, and other cathartics for three days, eating nothing meanwhile, growing steadily weaker, and vomiting frequently. The vomiting finally became stereoraceous. The patient walked into Dr. Abbe's office. The hernia was quite large, a left oblique inguinal, and descended into the scrotum a little distance. Taxis was tried for fifteen minutes without any benefit, and the man was sent home. A few hours later he was visited, with the intention of operating, but before this was done taxis was repeated for about fifteen minutes, with some force, but very carefully. Upon cutting down, a piece of intes-
tie consisting of two coils was found, of a dark mahogany-
color, but not gangrenous in appearance. The finger could be
passed quite easily within the neck of the sac. The constric-
tion was found to be at the internal ring. This was divided,
and reduction was easily accomplished. Before it was returned,
the gut was noticed to be very much colder than the rest of this
intestine, and it was thought that this cold body in the perito-
neal cavity might have added to the shock which followed.

The thick sac was dissected off to make the operation a
radical cure. The eamsl was closed with two deep silver
sutures, and the integument by catgut, and a drainage-tube
inserted.

The patient rallied a little after coming out from the anes-
thesia, but then sank again and died, from shock, five hours after
the operation. No autopsy was made. It occurred to the doc-
tor that perhaps the repeated taxis had increased the shock.
He should not employ it in another case of the same duration,
for, had a slight ulceration at the neck been present, rupture of
the intestine was almost inevitable, no matter how carefully
taxis was made.

Dr. E. J. Hall had recently read a review of a paper advis-
ing prolonged and repeated taxis, in which this was severely
criticised. He himself was opposed to it, now that the danger
of the cutting operation had been so much lessened by the em-
ployment of thorough antisepsis. In regard to the point that
it was shock rather than septicemia that caused death most fre-
quently, he said that it was the shock of the strangulation rather
than that of the operation. Many German surgeons were com-
ing to regard shock after operations as always dependent upon
septicemia.

Dr. L. E. Holt thought we should be governed in our em-
ployment of taxis by the acuteness of the symptoms. It was
manifestly useless to prolong taxis in those cases of primary
strangulation in which severe symptoms developed in a few
hours, as the constriction was usually very tight, and every
hour that the operation was postponed diminished the chances
of success. In cases where the symptoms were three or four
days in coming on the case was different.

Salivary Calculus.—Dr. Abbe also related a case of calcul-
us of Wharton's duct and presented the specimen, which was
of the size of a large pea. The patient was a man of thirty,
who for two months had been suffering from what was sup-
posed to be an ordinary abscess in the floor of the mouth open-
ing to the right of the frenum. An induration had existed
there for some months before suppuration took place. It ap-
peared like a sinus leading to necrosed bone, and, a probe being
introduced, something resembling this was struck. The sinus
was slit up, the small calculus was removed, and prompt recov-
ery took place.

Dr. C. B. Kelsey had come across one in the dissecting-
room, in the substance of the submaxillary gland, of about four
times the size of the one shown by Dr. Abbe.

Cancer of the Rectum.—Dr. Kelsey reported the follow-
ing case of cancer of the rectum high up, which had presented
great difficulty in diagnosis in its early stage. The patient was
a gentleman of forty-eight, without any family history of can-
cer, who came to the doctor saying he had hemorrhoids. For
two weeks he had complained of pain in the sacrum, which was
so severe as to keep him awake at night. He had had a sort of
diarrhcea for the same time, the passages being streaked with
blood. On examination, nothing whatever was found. A full-
sized bougie was passed in its whole length. An enema of three
pints was given easily. These signs were thought sufficient to
exclude stricture. The patient had an attack of dysentery three
years before, but no rectal symptoms until two weeks before.
By exclusion, Dr. Kelsey arrived at the diagnosis of cancer high
up, although the general condition of the patient was excellent,
and no infiltration could be made out.

Bismuth and morphine suppositories were ordered with the
effect of relieving him of his bloody diarrhcea in a week. He
was then sent to Europe. On his return, a few months later,
the cancerous cachexia was well marked, and the infiltration
could be felt through the abdominal walls. Rectal symptoms
were absent, however. So firmly convinced was the doctor
upon his first examination of the diagnosis of cancer, that, had
he believed in the operation, which he did not, he should not
have hesitated to cut down, with the idea of excising the growth.
Of the ten patients on whom the operation had been done, five
had died immediately after the operation, and the remainder had
not lived longer than they otherwise would have done.

In reply to the question, whether he considered a fixed pain
in the sacrum pathognomonic of cancer high up, Dr. Kelsey said
that he did, when it was associated with a mucous bloody dis-
charge, and no other cause could be found for the symptoms.

Dr. Abbe asked if an acute exacerbation of an old dysenteric
ulcer might not give similar symptoms, though not visible on
examination.

Dr. Kelsey thought it would not produce the same fixed and
severe pain.

Syphilitic Disease of the Rectum.—Dr. Kelsey reported
another case of ulcers of the rectum, undoubtedly syphilitic,
promptly cured by local treatment, in which constitutional
measures had produced no beneficial results. The patient had
suffered from gummata in various parts of the body, and gave
a clear history of syphilis. For several months he had suffered
from pain in the lower part of the abdomen and a mucous dis-
charge. He had been at the Hot Springs for treatment, and
had been saturated with mercury and the iodides. On exami-
nation, there were found just within the sphincter two ulcers,
one an inch, and the other nearly two inches in diameter.
They were not elevated, and could be easily felt with the finger.
Strong nitric acid was applied, and the patient was put upon a
milk diet and kept in bed. The pain disappeared at once, and
in a month they were perfectly healed.

Toxic Spasm of the Trapezius Muscle.—Dr. Holt related
a case. [See p. 629.]

Dr. V. P. Gihney said he had searched through the litera-
ture of malarial paralysis and spasm recently, and had come to
the conclusion that these cases were very rare. He was inclined
to regard this case as one, however. Tenderness he had invari-
ably found present in muscular spasm from cold. Electrical sen-
sitivity was also increased. He would like to have seen what
effect the strong galvanic current or actual cautery, which lately
had been so highly recommended by some authorities, would
produce in this case.

After-Pains.—The Chairman reported a case of unusually
severe after-pains in a multipara who was delivered of twins.
Labor came on about two weeks before the expected time, and
had been several hours in progress when he saw the case. After
the first child was born, which had presented by the vertex and
was of small size, another was found, also presenting by the
vertex, and the cord was prolapsed. Pulsion had ceased. While
waiting for the forceps, exerted was administered. The
forceps was applied and a somewhat larger child than the first
was extracted, deeply cyanosed. It breathed afterward, but
finally died cyanotic in five hours. The cyanosis he thought due
to cardiac disease, and not to the protracted delivery. The after-
pains were the most severe he had ever seen. Opium in large
doses was tried, then quinoline, then turpentine suppes; all proved
ineffectual, and the inhalation of chloroform was resorted to at
intervals for thirty-six hours before the pains ceased. The
placenta was large and single; two cords were present.
Dr. Holt asked whether any member of the society had ever used gelsemium for after-pains. In a patient recently who could not bear opium, and in whom all the usual local applications had given no relief, he had used the fluid extract, in doses of a fraction of a drop, frequently repeated. The pains were very severe and very prompt, and decided relief was experienced.

Dr. F. P. Foster thought gelsemium an uncertain and a dangerous drug under any circumstances. He referred to several cases of death attributed to its use in medicinal doses.

Dr. J. E. Winstens had often used the fluid extract in tendinum doses in neuralgias, and had never seen any bad effects produced.

L. Emmett Holt, M. D., Secretary.

Reports on the Progress of Medicine.

ANATOMY AND PHYSIOLOGY.

By Graeme M. Hammond, M. D.

On a Method of demonstrating the Connections of the Brain in Health and Disease.—Dr. D. J. Hamilton ("Brain," July, 1888) states that to investigate the course of the brain fibers the organ must be completely hardened into the center. The hardening fluid to be employed is a mixture of Müller's fluid, three parts; methyl alcohol, one part.

This mixture must be kept in the dark and not made until it is going to be employed. The brain must be injected on three successive days from one vertebral and the two carotids. Between fifty and sixty ounces should be injected the first day, and from thirty to forty on the second and third days. Considerable force should be used in injecting the fluid, but care must be taken not to rupture the membranes. The brain should now be kept in a large jar filled with the same fluid. In a month from the last injection it should be cut into slices one inch thick and placed in the hardening fluid for another fortnight. To complete the hardening, place the segments in pure methylated spirit, separating one from the other by pieces of linen, and leave them for two weeks. To color the convolutions, dry them by exposure for two or three hours, and, after adjusting the segments, rub gold size, mixed with vermillion, lamp-black, or oxide of zinc, into the membranes with a camel's-hair brush. The only method by which these sections can be cut is by freezing.

First let the sections remain in water, which must be constantly renewed, for three days, then place them for a fortnight in the following solution:

- Sirup (1 ounce, by weight, crystallized sugar to 1 fluid-ounce of water) .................................. 4 ozs.
- Mucilage (1 pound gum acacia to 80 ounces water) ....... 5 "
- Water ............................................. 9 "

Mix and saturate by boiling, with boric acid. Filter through muslin. The sections are cut in a microtome purposely constructed for frozen sections, and are thrown into a dish of water in which is a sheet of glass covered with the following preparation:

Soak a quantity of French gelatin in water for half an hour, melt, and measure it. Take three times as much water and add sufficient carbolic acid to make a one-to-forty mixture. This should be applied just before the section is cut, and should be firm but not dry. The section is raised out of the water on this plate, drained, and covered with the same solution applied hot. When dry, brush over the specimen, and for two inches beyond, with liquor potassae (Brit. Pharm.). Leave it five minutes, and set in a cool place for twenty-four hours. Now cut the gelatin around about an inch from the preparation and strip it off. If it is now placed in water it expands to nearly double its original size, the gray matter remains transparent, and every bundle of fibers in the white matter is clearly marked. The specimen should be mounted on glass in glycerine jelly, and the edges of the cover glass cemented down with the following:

- Gum damar ......................................... 8 ozs.
- Benzol ............................................ 8 fluid ozs.

Dissolve, filter, and rub in 7 drs. of oxide of zinc.

The Encephalic Center of Perception; its Site and Secondary Nature.—Brigade-Surgeon T. Oughton ("Lancet") remarks that by center, in neurology, is usually meant an anatomical disposition of gray neurium (gaudium), marking the afflux and efflux of nervous currents. The centers of secondary perceptions may be typified by the center of motion of a gyrating wheel, both being effected by an intrinsic reacting on an extrinsic force; in the case of the wheel, its intrinsic shape and pivoting react on the applied force to generate a plane of motion together with its center, and in the place of the perceptions, collectively, the intrinsic force of sensation reacts on the extrinsic force of a secondary (muscular) perception, to produce a center of apparent direction holding a defined relationship to the corresponding objective by its gyrations about by muscular influences. Every articulation in exercise during voluntary motion is more or less a center of secondary perception. Our further analysis of the present topic will consist in reducing all secondary perceptions to one or other of three planes of direction, either isolated or combined—namely, (1) an antero-posterior vertical plane, having reference to all dextral and sinister perceptions; (2) a lateral vertical plane, related to all forward and backward perceptions; and (3), a horizontal plane holding relation to all upward and downward perceptions. It will be obvious that the points of intersection of three such planes will mark the position of the required center. The first, or antero-posterior plane, is described about the median line of the body. The second, or lateral plane, is described on a line uniting the two external auditory meati. The third, or horizontal plane, is very distinctly definable by experimental observation as one that is described on a line uniting the two centers of visible direction (binocular axis). Thus an ultimate fact is offered for consideration—namely: that the encephalic center of perception coincides with the point of intersection of a vertical plane that is median, a lateral vertical plane corresponding with the line of juncture of the external auditory meati, and a horizontal plane corresponding with the binocular axis. The said center is only in efficient operation during the most natural of conditions; let these exist, but the slightest abnormalities, even monocular vision, and other centers, come into an independent action, clearly evidencing that the center of perception is not the center of every perception.

The Doctrine of Motor Localizations in the Cortex of the Cerebral Hemispheres of Man.—Claret and Pitres ("Revue de médecine"), after thoroughly investigating the observations contradictory to the theory of cortical motor localizations, reject them for the following reasons: First, because they refer to cases of intra-cranial tumors. Second, because they are cases confused with multiple or diffused lesions. Third, because they are accompanied by clinical histories and post-mortem examinations that are either manifestly erroneous or else incomplete. A number of cases are cited, and the pathological conditions and the symptoms arising therefrom are given, together with the reasons why they can not be accepted as evidence contrary to the theory of motor localizations.

In concluding the subject, the brain is separated into two zones: the one non-motor, in which destructive lesions are
never accompanied by permanent paralyzes; the other motor, in which destructive lesions always produce permanent paralyzes on the opposite side of the body. The non-motor zone comprises (a) the prefrontal region (orbital lobe, and 1st, 2d, and 3d frontal convolutions); (b) the occipitoparietal region (occipital lobes superior and inferior parietal lobules); (c) the temporoparietal lobes.

The motor zone comprises only the ascending frontal and ascending parietal convolutions, and the paramentral lobes.

Whether paralysis, due to a destructive lesion of the cortex, is total or partial, it is, after a certain interval of time, always followed by secondary contractions in the paralyzed muscles and descending degeneration of the pyramidal fasciculi.

Irritative lesions of the cortex give rise to epileptiform convulsions, which can be distinguished from true epilepsy by the presence of a motor aura, either limited to one side of the body (hemispa-rum), or to a single group of muscles (monospasus). Generally the lesions provocative of epileptiform convulsions are situated in the neighborhood of the cortex, a destruction of which would be followed by paralysis of those muscles which are first convulsed by the advent of the aura.

Miscellany.

Therapeutical Notes.—Turpentine in Secondary Syphilis and in Phlegemnic Sores following Fever.—Deputy Inspector-General Nicholson, M. D. ("Medical Times and Gazette," September, 1888), gives some of his personal experience with "this most useful medicine" in these two classes of cases. In a depot hospital that fell under his charge were two patients, both of whom had had syphilis, and, after having been discharged, had returned to the hospital with phlegmonic plaques—induration of the skin and of the subcutaneous tissue above and below Poupart's ligament. Both had apparently recovered under the use of iodide of potassium and rest, but both had quickly suffered a relapse. On their return they hobbed about with difficulty. They were put to bed and given iodide of potassium internally, and local compression was made by means of, leaden plates and bandages. They improved apparently, and one of them soon pronounced himself, and seemed to be, quite well. However, because of his previous relapse, he was kept under treatment a while longer, and then put on light duty as a convalescent. But he soon came back in as bad a condition as ever. The former treatment was resumed, and both he and the other patient were also given turpentine, in drachm doses twice a day, made into an emulsion with liquor potassium and water. Both were promptly cured and discharged. As neither of them returned, their cure was presumed to be permanent. Another similar patient, treated in like manner, was likewise cured, though his case had previously resisted all treatment.

[Dr. Nicholson's] success in phlegmonic plaques led him to try turpentine in orchitis from various causes, in venereal buboes, suppuring and non-suppurating, and in other swellings, but without the slightest success.

In West Australia, a lad of ten was attacked with a continued fever, which was apparently endemic in that region. It was mild in type and had never proved fatal. The boy, though well nourished, was not very strong constitutionally. His convalescence threatened to assume that chronic ill-health that sometimes follows typhoid fever. During its course he was unexpectedly attacked with two indolent phagedenic, yellow-colored sores, one, somewhat superficial, over the right trochanter, the other, deeper on the front of the middle and upper part of the left thigh. The former exposed the tendon, and the latter laid bare more than an inch of the femur. The edges of the ulcers were swollen. Vigorous local treatment, in conjunction with the internal administration of tonics and alteratives, failed to effect a cure. Turpentine was at length resorted to, in twenty-minim doses. Improvement followed, at first quite slow and gradual, afterward more rapid and satisfactory, so that the sorer seemed advancing to a speedy cure. In the absence of Dr. Nicholson for a week or so, the case was temporarily under the care of another practitioner. The latter left off the turpentine and local compression, as the patient was progressing so favorably that they did not seem to be needed. A change for the worse was the result. And, though the sore on the trochanter healed slowly when the previous treatment had been resumed, it was months before the larger one on the thigh could be made to heal. The child never enjoyed good health again. He was pale, emaciated, with a slightly yellow look, and lame from the serious loss of flesh about the ulcer on the thigh, so that he could go about only in a handbarrel. He did not long survive, though the particulars of his illness and death escaped the knowledge of Dr. Nicholson, who had changed his residence.

Dr. Nicholson concludes his paper by saying: "Whether I tried turpentine in this case, as a local application, I can not now distinctly remember. If I did not, it was, I think, a regrettable omission."

In Sulphate of Cinchonidine or Onxytoci—Dr. W. O. Henry, of Pawnee City, Neb. ("St. Louis Medical and Surgical Journal," November, 1888), has made some observations in his own practice to satisfy himself whether or not sulphate of cinchonidine has onxytotic properties. He believes this question to be one of no little practical importance to physicians who practice in "malarial" regions. Women from three to six months pregnant, when attacked by malaria, are very apt to present symptoms of abortion. If it be desired to administer cinchonidine in such cases it would be unwise to doubt whether this agent would increase the tendency to abortion. Dr. Henry cites three illustrative cases and says: "From these and other considerations I conclude as follows:"

1. Cases of threatened abortion, of malarial origin, are controlled by cinchonidine by reason of its specific powers.
2. When labor has begun, cinchonidine will increase the strength and duration of the pains, in consequence of its general tonic properties.
3. Cinchonidine will not, in any case, in ordinary doses, originate uterine contractions.
4. If these conclusions are true, as I believe them to be, cinchonidine is not, properly speaking, an onxytotic."

The Use and Abuse of Pessaries.—This subject has before now been discussed from the point of view of the proper selection of cases in which pessaries are or may be useful. The subject has various bearings. In the first place, the statistics of Vedeler and Hermann, quoted in this journal, show that anteflexion is more normal than any other condition in multiparous women, and that flexions, as flexions, do not, as a matter of fact, cause dysmenorrhea. It is impossible to conclude that if flexions do not cause the most direct of all uterine symptoms—dysmenorrhea—they will cause the symptoms known as indolent or retentive, for, to test of which we refer our readers to the text-books passim, and which include almost every ailment to which female flesh is heir. This being the case, it follows that flexions, as flexions, should not be treated. But, secondly, we will suppose a typical case in which pessaries are known to do good—namely, more or less descent of the uterus, with or without retroversion or retroflexion (which are most probably indications of descent), and we will suppose a pessary to be inserted—what amount of attention (i.e., attendance) should this entail? Undoubtedly a woman wearing a pessary should not be sent away ignorant of its presence, and without any directions. She should therefore be informed that such an instrument has been inserted; and she should be given certain directions. Thus, it is advisable at once to tell her that it is well to wash out the vagina once or twice a day with simple water, which will prevent secrations from accumulating, decomposing, and causing a noisome smell (which in some cases is bad enough to suggest the presence of cancer); she should also be told that soreness, itching, or profuse discharge indicates that the pessary should be seen to, and, generally, that it should not be worn without being seen to three or four times a year. It is also usually advisable that the doctor should satisfy himself in a week or so that the pessary is doing good, and doing no harm, and then, having once started the treatment, the patient should be left to test its efficacy. Now, this test implies the
removal of some symptoms or symptom, which may justly be attributed to some former morbid condition, and it also implies the locomotion of the patient. Generally speaking, a patient lying down is better without a pessary, whatever displacement is present; thus it is rare for even complete procidentia not to reduce itself, or become much smaller, when the patient lies down, and the symptoms of partial descent, which (if there are any symptoms at all) will include almost certainly a sense of weight and dragging pain in one or other big fossa, will disappear, or become greatly diminished, in the recumbent position. A pain which is better when the patient is standing and worse when she is lying should be regarded with suspicion if supposed to be due to some local cause alone; it is probably nothing of the kind. There is to relieve pains increased by standing that pessaries are most generally useful. If this is not effected, the uterus may be unquestionably in the "normal" position, but the pessary is useless, and, if useless, injurious. Thus, the proper use of pessaries is first, in most cases, after the insertion of the pessary, to get the patient on her legs; secondly, to satisfy one's self in a few days that it is doing good and is doing no harm; but, as soon as both these objects are attained, to send the patient away to test the treatment, with the above directions. It should not be the task of months to fit a woman with a pessary, any more than with a truss. The following are not instances of the proper use of pessaries. To keep the patient in bed for long periods wearing a pessary; to see her every day, every other day, twice a week, for weeks, months, or years. Perhaps such visits are not made to the patient, but to the pessary. However that may be, it is not the pessary, but the patient, who has to pay. What should we say of a surgeon who called for months to see a patient to whom he had given a wooden leg or a truss, and who kept him in bed for long periods; or of an oculist who had fitted a patient with spectacles, and saw him every day for several months, whether the spectacles seemed to suit him or not? It is true that the pessary is a truss in the dark, but that is no reason why the management of a pessary should be a deed of darkness. Recent investigations have shown that the whole question of displacements has to be reconsidered. It can not be too widely or too dogmatically stated that prolonged treatment by pessaries, such as we have described, is quite inadmissible and unnecessary; and, if unnecessary, injurious not only to the patient—i. e., to her morale as well as her purse—but also, in the best sense, to the practitioner; and, if to the patient and practitioner, then to the public and the profession. It should also be realized that a pessary is a mere form of truss, and that its operations, though removed from the general view, are not occult. Ill-treatment bids fair to bring this useful form of truss into disrepute, and we are daily expecting to meet the practitioner whose sensitiveness is such that he shrinks from a cure whose name he has learned to mistrust and dislike; but we feel bound to say we have not come across him yet. —Lancet.

PETERHISTTREPHINING.—Mr. T. F. I. Blaker, M. R. C. S., writes as follows to the "Lancet": "That many operations in surgery were practiced in remote times is undoubted, but I think few surgeons realize how very ancient indeed is the operation of trephining, or, as it was formerly called, trepanning, the skull. During recent years some curious discoveries have been made in France and elsewhere conclusively proving that trephining was practiced by neolithic man, and, further, that the operation was oftentimes successful. These later stone-age men must have inhabited Europe several thousand years ago, and were, of course, excessively barbarous, ignorant, and superstitious. Indeed, it was their very superstition which led them to trephine the skull. Dr. Procopii informs us, and he has given the subject his greatest attention. Trephined human skulls have been found by Dr. Franquières of Toulouse in the cave of Homme Mort in the Department of Lotzro, in the caves of La Marne and of Lozère, near Pau, in the Canary Isles, in Algeria, in Mexico, and in Peru. The operators had, of course, no better instruments than more or less perfectly sharpened flints, and with such rude tools they performed their operation. First a V or T incision was made down to the bone, the flaps were retracted by assistants, and the bone was then, persistently scraped until at length an opening was made sufficiently large to expose the brain and its membranes. This opening was a viaticum or way of escape for the demons who had taken possession of the body and were causing the epilepsy or insanity, for such were the 'cases' which were operated on. When, after considering the class of cases, the desperate nature of the operation, and the barbarism of the operators of the after-consequences—e. g., hemorrhage, blood poisoning, eye-siepas, the danger of injury to the brain, the want of proper nursing, and bad hygienic surroundings generally—it is wonderful that any one patient should have recovered; and yet, incredible though it seems to be, Dr. Franquières states that out of twenty skulls in his possession (all of which were trephined during life) nineteen of them exhibit inculcable signs of having recovered from the operation. This is shown by the fact of the edge of the bone having become smooth in consequence of the cells of the diploe having become covered by the newly formed bony tissue. The discs of bone which were separated from the skull during the operation were looked upon as talismans possessing vast therapeutic power and capable of counteracting witchcraft, and of preserving the possessor of them from disease. These talismans were therefore worn round the neck as amulets, and were considered as of priceless value.

"The death of a patient who had survived the operation, it was considered 'only fair' to give the original possessor of the piece of bone so highly prized his own back to him once more. Professor Broca tells us that this was done in order that the deceased might carry with him into the next world this talisman, and so be preserved from the torments of the evil spirits which had haunted him on earth. This, says Professor Broca, is the earliest indication we have of a belief in a life beyond the grave. There is a touch of humanity to be discerned both in the operation itself and also in the restoration after death of the precious amulet to its rightful owner. This is the more remarkable when we consider what 'untutored savages,' if not cannibals, these neolithic men were."

THE INTERNATIONAL MEDICAL CONGRESS OF 1884.—We lately published the provisional programme of the section on psychiatry and neurology of the International Medical Congress to be held in Copenhagen next August. That of the section on obstetrics and gynecology is as follows: 1. The Antiseptic Method in Laparotomy, Dr. Mikhailov. 2. Launay in Laparotomy. 3. Early ovariotomy, Mr. Knowles, Thornton. 4. The Treatment of Fibro-nymotus of the Uterus, Professor Schroeder. 5. Ovariotomy for Fibro-nymotus of the Uterus. 6. Ovariotomy for Nervous and Mental Diseases, Dr. Hegar. 7. Vaginal Expiration of the Uterus for Cancer, Dr. Schroeder. 8. Dilatation of the Uterus. 9. The Operative Treatment of Prolapse of the Uterus and Vagina. 10. Ovulation and Menstruation. 11. The Operative Treatment of Extra-uterine Pregnancy, Dr. Litzmann. 12. On an International Obstetrical Nomenclature, Dr. A. R. Simpson. 13. Aluminum Gravidarum, Dr. Halbertsma. 14. The Treatment of Abortio, Dr. T. G. Thomas. 15. The Management of the Placenta, Dr.
Professor Dubois-Reymond.—The twenty-fifth anniversary of the appointment of the eminent scientific worker, Dr. Emil Dubois-Reymond, to the chair of physiology in the University of Berlin, has lately been celebrated. On the death of the celebrated Johannes Müller in 1858, the chair of Anatomy and Physiology, which he had long held with distinction, was divided, the anatomical department being assigned to Professor Reichert, then of Breslau, and the physiological to Dr. Dubois-Reymond, who had been an extraordinary professor since 1855. On October 20th, a large number of Dr. Dubois-Reymond's pupils assembled in the Physiological Institute, and presented him with his bust, and a "Jubilee volume" (Jubelband) of the "Archiv für Anatomie und Physiologie." The presentation of the bust by his oldest assistant, Professor Heidenhain, of Breslau, while the volume of the "Archiv" was presented by Professor Rose Nathal, of Erlangen, both of whom made congratulatory speeches. Addresses of congratulation were also delivered by Professors Virechow, Munk, Fritsch, Hirsch, and others; and similar tokens of respect were received from Professor Holmgren, of Upsala, Professor Tschirnich, of St. Petersburg, and the Faculty of Medicine of the University of Aberdeen. On the following day, a dinner was given in honor of Professor Dubois-Reymond by his colleagues, pupils, and friends.—British Med. Jour.

The University of Würzburg.—The new anatomical department was opened on the 5th of November. The "Medical Times and Gazette" states that Professor Kölliker delivered an address in which he sketched the history of anatomical instruction in Würzburg. Dating originally from 1719, the department was reorganized in 1788, when the famous surgeon von Siebold delivered the opening oration. The building in which instruction was given remained unaltered until within quite recent times, and many well-known men have been connected with it, of whom Virchow and Kölliker are the most famous. The increase in the number both of the students and of the branches of science taught therein had long rendered the construction of a new anatomical school a necessity, and at length a building has been obtained which answers in all respects to the increased demands of modern science.

Nitrate of Sodium.—Dr. Sydney Kinger writes to the "Jamaic," to say that the dose of nitrate of soda should be small, two or three grains, and not as stated in his "Handbook of Therapeutics." It has been ascertained that, in the case in which twenty-grain doses were prescribed by Dr. W. T. Law, a year and a half ago, the specimen of the salt employed was very impure, containing a large percentage of the nitrate.

The Surgical Treatment of Renal Calculus.—At a recent meeting of the Sheffield Medico-Chirurgical Society ("British Medical Journ.," Nov. 10, 1883), a paper on this subject was read by Mr. Garrard, the chief part of which was taken up by the relation of two cases. In one he had successfully removed nephrectomy a uric acid calculus, weighing forty grains, from the pelvis of a man's kidney, at the Rotherham Hospital. The man had never had any symptom of calculus, except a deep sinus in his left loin, over the kidney. The wound was entirely healed in six weeks, without any bad symptom of any kind. The other case was one of strumous kidney, with pyelitis and perinephritic abscesses, which was at first thought to be a case of calculi. The kidney was explored, the pus evacuated, but no stone was found. After careful examination, a drainage-tube was left in. The patient at first went on improving, but ultimately, in three months, sank exhausted by the drain from the sinus, which never closed. A post-mortem examination revealed the fact that the kidney-structure was replaced by caseous tubercles, which had softened down, leaving nothing else than the capsule, inclosing a bag of pus, and only a small shell of recent phosphatic deposit. In conclusion, Mr. Garrard thought that cases of calculi would be found to show better results than any other cases of renal disease which were suitable for operative treatment; that nephrectomy, in such cases, would be found remarkably free from risk; and, while admitting the great difficulty of making a certain diagnosis in renal calculi, the exploration of the kidney was thoroughly justified, especially since large wounds were now much better treated than formerly.

Sudden Death in Hystera.—An instance of this rare occurrence having been reported by M. Mollière at a meeting of the Société des Sciences Médicales, of Lyons ("Lyon médical," November 11, 1883), M. Laures remarked that he had met with a similar one in which it was very difficult to determine the actual cause of death. The hysterical attacks arose from the pressure of a medullary tumor. He was also cognizant of a case closely analogous to Mollière's. It was that of a young female under treatment for hysteria in the Croix Rousse Hospital, who died from syncope on the third day after her admission. The results of the autopsy were entirely negative. A case precisely like this had previously occurred in one of the great Parisian hospitals. M. Mollière said that he was not aware of any recent incidents of the kind.

As Ethromaniac.—In the "Gazette des Hôpitaux," Dr. Sedau relates the case of a youth—one of the brightest and most distinguished scholars in his lyceum—who, when only ten years of age, contracted the habit of drinking ether for the purpose of stimulating his mental faculties. He gradually increased his allowance of the narcotic until it sometimes amounted to 1,000 grammes, or even to a litre, in twenty-four hours—partly swallowed and partly inhaled. In the intervals of intoxication he would solve the most difficult problems in the higher mathematics, and would then go out secretly at night, and even steal from his relatives, in order to procure the drug. All efforts to subdue the propensity proved unavailing, but his general health never seemed to suffer directly from its effects; and death, after many years of indulgence, was caused by natural insufficiency of ante-natal origin. Toward the last he had recourse also to subcutaneous injections of ether and morphine.

Army Intelligence.—Official List of Changes of Officers serving in the Medical Department of the United States Army, from November 24, 1883, to December 1, 1883.—Wolveston, William D., Major and Surgeon. Assigned to duty as post-surgeon at Washington Barracks, D. C. Par. 7, S. O. 222, Department of the East, November 27, 1883.—Brown, Paul R., Captain and Assistant Surgeon. Assigned to duty in the Department of Arizona. Par. 4, S. O. 273, A. G. O., November 28, 1883.—Merrill, James C., Captain and Assistant Surgeon. Removed from duty in the Department of the East, and assigned to duty at Columbus Barracks, Ohio. Par. 4, S. O. 270, A. G. O., November 24, 1883.—Brewster, William B., First Lieutenant and Assistant Surgeon. Extension of leave of absence granted September 18, 1883, further extended two months. Par. 4, S. O. 271, A. G. O., November 28, 1883.—Maddon, Thomas J. C., First Lieutenant and Assistant Surgeon. Granted leave of absence for two months. S. O. 136, Department of the Missouri, November 24, 1883.

Naval Intelligence.—Official List of Changes in the Medical Corps of the Navy during the week ending December 1, 1883.—Medical Inspector D. Kindred is to be relieved from duty on the retiring board on December 9th.

Society Meetings for the Coming Week.—Monday, December 10th: New York Academy of Sciences (Section in Chemistry and Technology). Tuesday, December 11th: New York Surgical Society; East River Medical Association (private); Medical Societies of the Counties of Chemung, Rensselaer, and Ulster, N. Y., and Morris, N. J.; Newark (N. J.) Medical Association; Jersey City Pathological Society; Trenton (N. J.) Medical Association (private). Wednesday, December 12th: New York Pathological Society; American Microscopical Society of the City of New York; Medical Societies of the Counties of Cayuga (semin-annual), Cortland, and Montgomery, N. Y., and Middlesex, N. J. Thursday, December 13th: New York Laryngological Society (annual); Society of Medical Jurisprudence and State Medicine (annual); Harlem Medical Association (private); Brooklyn Pathological Society. Friday, December 14th: Yorkville Medical Association (private); Medical Society of the Town of Saugerties, N. Y.
Original Communications.

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.*

BY T. GAillard Thomas, M. D., CLINICAL PROFESSOR OF DISEASES OF WOMEN IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

At a time when a flood of literature pours in upon the practitioner of medicine from numberless sources, upon every conceivable subject connected with his calling; when original ideas are spread out over space as gold-beaters hammer foil; and when the changes are rung upon every meritorious essay by a host of others which offer the reader merely the same thoughts in different words—it is pertinent and justifiable for every member of this audience to demand the motive, or, as our Gallic neighbors would express it, "the raison d'être," of a paper upon so trite a subject as the present, and one which has already received the attention of many of the brightest intellects devoted to obstetrics.

I accept this challenge to-night, and, before beginning my essay, shall strive to justify, if I can, its preparation. I freely confess that it contains nothing that is original, nothing which has not elsewhere been as fully and as clearly stated, nothing which has not already received careful consideration at the hands of the progressive obstetricians of the world. And yet I am not only emboldened to present it, but even to hope that it may be regarded as worthy of the attention of those who listen to its reading to-night, and that, in its dissemination among many in this country in whose medical pupilage I have taken part, it may accomplish good.

The plan of treatment for that hydra-headed monster styled puerperal fever, which I shall advocate, has nowhere, so far as my knowledge extends, been fully elaborated in any one essay, and carefully systematized; the various portions of the plan are not yet even generally accepted as orthodox; and many appear at this late date to have paid little attention to them in practice, even if they have seen them in print.

In support of these assertions I will refer to those two facts. In the year 1879, at a session of the American Gynecological Society in Baltimore, the question of intra-uterine antiseptic injection for the cure of puerperal septicaemia came up for discussion. It received very qualified approval, and, with one exception, if my memory serves me right, I stood alone in its strong and uncompromising advocacy. About a year ago I related, in a society of this city, the history of a bad case of puerperal septicaemia which was, beyond question, saved by the persistent and bold use of intra-uterine injections. This very desultory report was published in some of the medical journals of this city, and after its appearance I received a half-dozen letters from men at a distance in this country, asking how the injections were made, and other questions showing so great a want of famili-

* Read before the New York Academy of Medicine, December 6, 1883.
prolific ground for the development of sepsis and zymosis. Menses, scarlatinia, and varioloid, which give no very bad prognoses when they excite zymosis in the blood of the non-pregnant woman, commonly produce death when they act upon the blood of pregnancy.

Then the nervous system is in a plus state of sensitiveness and excitability, and influences which are very controllable in the non-puerperal state produce very evil results here. For example, an accumulation of urinary poisons in the blood produces convulsions; an untoward moral influence produces violent mania; and crude ingesta result in severe spasmodic affections in the alimentary canal which, in the same woman when not pregnant, would scarcely have attracted attention.

The local conditions which result from parturition are even more striking. The uterus and other pelvic viscera are, at full term, as fully supplied by lymphatics and lymphatic glands as is shown in this diagram;* and the arteries, veins, nerves, and other tissues of that organ, the vagina, the uterine ligaments, and the peritoneum have all undergone a rapid physiological hypertrophy, which permits of an organ only three inches in length ascending so as to touch the ensiform cartilage.

The uterus about the 280th day of gestation contracts and expels the child; then the placenta and membranes; and then closes its emptied cavity, and rests. Let us suppose that in forty-eight hours after delivery a primipara dies of pneumonia, and that we are allowed to lay open the genital tract and examine it from the fundus uteri downward. Outside all looks well; the uterus is merely much larger than in the non-pregnant state. Within, it presents a very different appearance; the whole endometrium, covered over by the greyish, sloughy-looking decidua vera, presents all over its surface an unhealthy, unclean, and diphtheritic look, although free from exudation. Here and there shreds of membrane, consisting of small portions of the decidua reflexa, which had become adherent, appear, partially detached and somewhat decomposed. At one point the large placental site is seen, raw, irregular, and covered over by minute traces of the placenta and small blood-clots which close the mouths of the uterine sinuses. The odor of the opened uterine cavity, the walls of which are thus covered, is disagreeable. The substances mentioned have for forty-eight hours been dislodging themselves and mingling with the pinkish fluid which pours like an unhealthy sweat from the placental site; constitute what is called the cleansings, or lochial discharge. Upon examining the cervix uteri, we find two or three small rents which pass through the mucous lining and involve to a varying depth the sub-lying parenchyma. In consequence of these injuries, and of absorption through them of the lochial discharge already mentioned, the cervix is swollen and edematous. As we examine the vagina it will be found that the great distension impressed upon it by the head of the child in its passage to the vulva has in two or three places caused a superficial rupture of the mucous lining of this canal.

We now arrive at the vulva, and here we find several solutions of continuity which have been effected by the escaping head. The fourchette has been torn through, and this rent has extended through a small portion of the perineum, and one or two small fissures have occurred in the mucous membrane covering over the osium vaginæ.

Werc we to take some of the lochial discharge from the vagina, after the atmosphere has acted upon it, and, abrading the inside of the finger with a lancet so that it bleeds slightly, apply this freely to the denuded surface, and allow it to become dry there, its irritating character would soon become evidenced by a burning sensation in the part, a smarting extending up the hand, and on the next day signs of a slight local inflammation, with a little lymphangitis, would be noticed. This would probably last only two or three days—merely long enough to demonstrate the fact that the fluid is an irritating one, but not sufficiently poisonous to cause erysipelas or severe angiolocutis.

The natural history of the ordinary local results of human parturition is given in the foregoing sketch. In every case of child-bearing the endometrium is thus incumbered and freed by a process of exfoliation and sloughing; in every case the cervix, vaginal mucous membrane, perineum, and vulva are, in varying degrees, lacerated; and in every case the offensive fluid, called lochia, poisons these freshly made, unprotected wounds. And yet what are the usual results? Recovery, uniformly, I might say universally, unless some unusual occurrence manifests itself to prevent this happy consummation! Theorizing about the matter, one would suppose that the mortality resulting from such a state of things must be excessive. Here we have a number of recent wounds constantly and unavoidably bathed with a fluid made up of dead and decaying animal tissue in a woman whose blood and nerve states are, with reference to septic disease, like flax prepared for the spark, and who is exhausted by pain, anxiety, loss of blood, and deprivation of sleep. Can one point to any concatenation of circumstances better calculated to insure a bad result? And yet the facts are these: only about one or two in every hundred parturient women ordinarily die when properly cared for during labor, even in public hospitals.*

Recovery, then, is the very general rule after normal parturition; death the rare exception. But now and then all this is changed. Some ferment or specific poison gains access to the genital canal and acts as rapidly and as decidedly as a little yeast added to dough. In the latter case, active and immediate fermentation affects the whole mass; in the former a set of striking, alarming, and often fatal phenomena occur, which spread dismay through the lying-in chamber and give an entirely new complexion to the progress of the case. The fact that this unfortunate occurrence has taken place will usually announce itself to the attending physician in this way. He leaves his patient on the morning of the third day cheerful, happy, free from pain, with a pulse of 85, and a temperature of 99°. He is called to her in the latter part of that day and finds that she has had a slight, perhaps a scarcely perceptible, chill; that some pelvic pain has followed it; that the lochia have ceased; that the milk which was just showing itself has disappeared; that

---

* Here Dr. Thomas showed diagrams, which we omit for lack of space.—Epron.

a severe headache exists; that a look of indescribable anxiety has replaced the happy expression of the morning; that the pulse rate is 130 to the minute, and that the buccal temperature is 104.°

A poisonous element has by some method or other reached the genital tract, as fruitful a field for its activity as a mass of dough is for yeast, and the result is already manifesting itself. Let us suppose that the patient's medical attendant lays the flatteringunction to his soul that all this is due to "malaria"; or that he soothes his troubled mind with the hope that it is "milk fever"; or that, recognizing the attack as one of "puerperal septicemia," or "blood-poisoning of child-bed," the first link in that terrible chain called puerperal fever, he relies upon medicines given by the mouth or rectum, what is usually the course shown as the natural one of the affection? Within a week, or thereabouts, for there is no rule as to this point, parenchymatous metritis, lymphangitis, lymphadenitis, phlebitis, cellulitis, or peritonitis will very probably develop itself, and what was originally merely a septicemia will merge into one of these affections, and the patient will pass through the peril attendant upon whichever of these pathological states manifests itself as a consequence of the initial lesion.

Sometimes the septic disorder develops puerperal malaria, while at other times a septic pleuritis, endocarditis, pneumonitis, periarteritis, or meningitis follows the systemic poisoning, the lymphatics emptying their deadly contents into the thoracic duct, and thus transferring them into the subclavian vein, as Lusk clearly points out. At other times the condition continues one of true and uncomplicated septicemia to the end, death occurring from coma, or the patient succumbing to exhaustion from hyperpyrexia, which lasts for weeks. What was originally septicemia, however, as a rule rarely remains so, but generally passes into some other disorder, and very generally into peritonitis, before a fatal termination occurs.

And now comes naturally the question, What is the pathology of that affection styled puerperal fever? An inquiry into the views which prevail among others would evidently require more time than I can possibly allot to it to-night; and yet I am desirous that my answer, even if very short, shall be so clear, succinct, and simple as to convey perfectly the opinion which a practice of thirty years has impressed upon my own mind concerning a subject which has always deeply interested me, and in connection with which I have had abundant opportunity for study, both at the bedside and in the dead-house.

My observations have led me to adopt the views of those who believe that puerperal fever is puerperal septicemia. It matters not whether it assume the form of metritis, phlebitis, cellulitis, peritonitis, or lymphangitis, the essence of the disorder is a poison, which is absorbed into the blood of the parturient woman through some solution of continuity, and which, in the appropriate soil of the puerperal condition, fructifies and produces the result known in its ensemble of pathological phenomena as puerperal fever. From my stand-point, the matter is well stated by Lusk* when he declares that "it has now passed beyond the domain of dispute that puerperal fever is an infectious disease, due, as a rule, to the septic inoculation of the wounds which result from the separation of the decidua and the passage of the child through the genital canal in the act of parturition."

As early as 1870, Heriveux, in his work on the diseases of child-bed, already alluded to, expressed himself on this point in the following words: "Here I stand; if what I have said does not carry conviction of the truth of my doctrine, fuller explanation will fail to do so. I believe in the multiplicity of puerperal diseases. I believe in puerperal poisoning as the source of them. Here, in two words, my creed is presented."

In 1877 the Berlin Obstetrical Society appointed a committee on puerperal fever, consisting of Schröder, Lohlein, A. Martin, Fasbender, and Boehr—men whose names are sufficient to command attention, even if their words fail to carry conviction. In its report this committee expresses its views thus: *"Under the names 'puerperal fever,' 'malignant child-bed fever,' are included a group of diseases occurring in child-bed which vary very greatly in their manifestations, but have this in common, that they are called into being by the absorption from the organs of generation of a material which gives rise to destructive inflammation and fever. There are, indeed, a number of substances, mainly composed of organic materials in a state of putrid decomposition, which, when brought into contact with an open wound, set up inflammation in it, which extends to the neighboring tissues; a further absorption by the lymphatics and blood-vessels leads to more extensive inflammation among neighboring and remote organs; and, when a large quantity is rapidly absorbed into the blood, a quickly fatal poisoning of the whole organism occurs. To surgeons the deadly effect of these materials upon wounds is only too well known, and the greatest advance, probably, which surgery has ever made consists in the so-called antiseptic method of treating wounds—that is, in the scrupulously exact removal of such materials from fresh wounds."

"Puerperal fever is indeed nothing else than the infecting of fresh wounds, such as are found in every newly delivered woman, with these destructive septic materials. Almost every woman, after labor, has small wounds on the external genital organs, which are caused by the passage of the child through this narrow opening, and in every newly delivered woman the inner surface of the uterus, from which the protecting membrane has been cast off with the ovum, presents a large wound surface. Thus, every newly delivered woman is liable to suffer from the dreaded infective wound diseases, which, in persons wounded under other circumstances, are called pyaemia, septicemia, wound-fever, blood-poisoning, purulent infection, etc., so soon as suitable septic materials are brought into contact with the genital organs."

And now a few words upon the nomenclature of this disease, which for so long has been known under the names of puerperal fever, child-bed fever, lying-in fever, and the names of the various special affections which develop in its course—phlebitis, lymphangitis, etc. Of late an effort has been made, which I think has emanated from that school of

obstetrics which has shed so much lustre upon our art, and enriched with so many eminent names the obstetric register of the world—the Dublin school. By members of this it has been urged that the name metriæ should supplant that of puerperal fever.

I for one sincerely trust that the suggestion will never be adopted. In what is the new name better than the old and faulty term? Does it convey any more accurate pathological facts to the minds of the student? Does metriæ exclude any chance of error as to pathology, or advance the clearness of understanding in any wise? I think not. Of the two terms it appears to me that, while both are objectionable, metriæ is the more so.

On the other hand, puerperal septicæmia conveys to the student and to the practitioner a clear and definite idea, which appears to be in consonance with the truth as taught us by modern pathology. In spite of the fact that important complications commonly result from the initial lesion, it appears to me that the influence of this is so paramount that its title should be adopted in spite of the fact that it is far from being absolutely perfect.

I should willingly, for the present, accept the reservation offered by Dr. Robert Barnes,* when he says: "I would propose that the word should not assume that a distinct, specific poison, or septicæs alone, is concerned, but that it should be used comprehensively as a general term, implying that the blood of the puerpera is imprisoned"; and this although I do believe in the existence of a specific poison, which is the great factor, as surely as I believe in such a factor in the production of typhus or variola.

What is the nature of this subtle and deadly poison, which, entering like a ferment into the genital canal of the puerperal woman whose blood is hyperinosed, whose nerves are in a condition of hyperesthesia, whose utero-placental vessels are partially open, whose cervix uteri, vagina, and vulva are covered with fresh superficial wounds, and whose womb is pouring slowly forth a fluid composed of dead tissue, decomposed blood, and recently exfoliated cells, gives rise to so much disturbance? What do we know of the poison? what is its natural history? what encourages its life? and what kills it, or cripples its activity?

Unfortunately, these questions can not to-day be satisfactorily answered; but have such questions been any more satisfactorily answered with reference to scarlatina, measles, and varicella? German pathologists have proved that the presence of microcoeci, more especially of the round bacteria, occurs so frequently in the pathological products of puerperal disease as to lead to the conviction that they are important factors in reference to them; but this point, like many others connected with the influence of bacteria as morbid ægents, is yet too unsettled for admission into a practical treatise like the present.† Inquiry into the matter is now being pushed with vigor in the laboratories of France and Germany, and we have, according to recent reports, a fair prospect of valuable and practical results.

But, even although we do not at present know the exact nature of the poison which proves the disturbing element in these cases, we surely know that some such toxic ægent exists, and it behoves us to learn how to prevent its entrance into the genital tract, and how best to destroy its life or its activity if it should gain admission in spite of our care and watchfulness.

Whatever be the character of this agent, we know that there are two, and only two, methods by which it can reach the parturient tract and exert its baneful influence. First, it may be carried to the vulva and into the vagina through the open orifice of that canal by the atmosphere, in which it floats as an impalpable substance; and, second, it may be carried to any part of the genital tract by the fingers of doctor or nurse; by towels or cloths laid against the vulva; by sponges used in washing; by instruments used in the delivery of the child, drawing of urine, or injecting the vagina; and from the bed-clothing and body-clothing of the patient which are in immediate contact with the sexual organs.

As this paper is already assuming proportions greater than those which I originally prescribed for it, I shall deal with this part of my subject rather dogmatically, offering a number of propositions which will embody in a few sentences what would otherwise demand a great deal of space for its enunciation. I shall address my remarks chiefly to the management of cases of midwifery occurring in private practice, as the wards of hospitals have long been subjected to systematic rules, while my observation in the capacity of consulting physician positively convinces me that in private practice, even among the wealthy who can command every safeguard and procure every luxury, there exist a want of system and an apathy as to preventive measures which border very closely upon criminality. To-day, when it is so generally agreed among the ablest obstetricians of the world that puerperal fever is the result of a special poison, and that prophylaxis against this is, by close attention to very simple details, perfectly practicable; it is the duty of every practitioner to guard his patient against danger by every means in his power. If he accept the views which this paper adopts, his duty is clear; it is equally incumbent upon him to give his patient the benefit of the doubt if he reject them.

Propylætic measures which should be adopted in all midwifery cases, whether they occur in hospital or in private practice:

1. The room in which the confinement is to take place should have the floor, walls, and furniture thoroughly washed with a ten-per-cent. solution of carbolic acid or mercuric bichloride, 1 to 1,000, and the bedstead and mattresses should be sponged with the same solution. Curtains, carpets, and upholstered furniture should be disinfected with as far as possible.

2. The nurse and physician should take care that all their clothing, both upper and upper, be clean and free from exposure to the effluvia of any septic affection. Should either of them have been exposed within a fortnight to the effluvia of such affections as scarlet fever, typhus, erysipelas, septicæmia, or the like, they should change every article of

† In reference to this part of our subject I would refer those interested to the chapter upon it by Professor Lux, in his masterly book upon the "Science and Art of Midwifery."
THOMAS: THE PREVENTION AND TREATMENT OF PUERPERAL FEVER. 653

clothing and bathe the entire body, especially the hair and beard, with a reliable antiseptic solution; that which I prefer for this purpose is a saturated solution of boric acid.

3. As labor sets in, the nurse, having thoroughly washed her hands, cleaned her nails with a stiff nail-brush, and soaked them in antiseptic fluid, should administer to the patient a warm vaginal injection of antiseptic character; bathe the vulva and surrounding parts freely with the same; repeat this every four hours during labor; and keep a napkin, wrung out of the warm antiseptic fluid, over the genital organs until the birth of the child.

4. Before assuming the functions of their respective offices at the moment of labor, both doctor and nurse should wash the hands thoroughly with soap and water, scrub the nails with a stiff nail-brush, and soak the hands for several minutes in a bichloride solution, 1 to 1,000.

5. The first two stages of the labor having been accomplished, the third stage should be efficiently produced; all portions of placenta and membranes removed; and ergot administered, in moderate dose, three times a day, and kept up for at least a week, for the complete closure of the uterine cavity, expulsion of clots, and occlusion of the uteroplacental vessels.

6. The doctor, taking nothing for granted, not satisfying himself with a vague report of the nurse, should, at the conclusion of the labor, carefully examine the vulva of the patient. If the perineum be lacerated, it should be closed at once by suture, to shut up this avenue to septic absorption; and, should slight solutions of continuity be found in the labia or the vulvar extremity of the vagina, these should be dried by pressure of a linen cloth, touched with equal parts of sol. ferri persulph. and carbolic acid, again dried thoroughly by pressure with the cloth, and then painted over with gutta-percha collodion. If this be thoroughly done, absorption will be prevented at these points for at least three or four days, when the application may be repeated.

7. In six or eight hours after the labor, when the patient has rested, the vagina should be syringed out with an antiseptic solution, and a suppository of cocoa butter, containing from three to five grains of iodioform, should be placed within it, under the os uteri. A syringe with intermittent jet should be used, which will wash away with gentle force all blood-clots, and reliance should not be placed upon the feeble drip of the fountain syringe, the advantages of which are, I think, entirely theoretical.

8. These vaginal injections and suppositories should, in cases of normal labor, be repeated every eight hours; in cases of difficult or instrumental labors, twice as often; and they should be kept up for at least ten days, the nurse observing to the last the precaution already mentioned of washing her hands before every approach to the genital tract of the patient.

9. When catheterization becomes necessary, it is safer to employ a new gun-clastic catheter, which before use should be thoroughly immersed in antiseptic fluid, and which should be destroyed at the conclusion of the case, rather than to trust to the nurse’s cleansing of an old silver instrument which bears within it the register of a list of cases of septicemia in which she has employed it during the past two or three years. It is a very common and very bad habit for nurses to own silver catheters, which they carry about with them from case to case of midwifery.

10. Last, but by no means least, let the physician inform himself by personal observation as to the competency of the nurse to syringe out the vagina thoroughly, to place the antiseptic suppositories just where they should be, and to use the catheter without injury to the patient. Neglect of this precaution has frequently resulted in leaving a fetid upper segment of the vagina entirely unwashed, while the antiseptic stream was limited to the lower third of the canal.

In a case in which I had performed anterior colporrhaphy and perineorrhaphy at the same time, in private practice, I was forced to withdraw my sutures and sacrifice the operations on account of a sudden rise of temperature to 105°. As I had become alarmed about the patient, I then used the syringe myself, and, to my great surprise and regret, found the upper portion of the vaginal canal filled with a decomposed mass of blood, which the constant but inefficient injections of the nurse had failed to remove.

Even if every suggestion made here be faithfully followed out in every case of labor which one attends in private practice, the trouble involved in the plan will not be great; and it will fall into utter insignificance when measured with the great comfort which will come to the mind of the obstetrician from the reflection that he has fully done his duty in exerting himself to the utmost to protect the vital interests which have been intrusted to his care. This feeling, which would be pleasant if no untoward event occurred, would be tenfold more so if a fatal issue should give rise to the painful inquiry as to his having fully acquitted himself of his duty in respect to prophylaxis. In the past this unpleasant question has not been often raised, but, as society at large becomes more thoroughly informed upon the prolific subject of the germ theory of disease, it appears to me that he will stand first who can point to a clear record of strict attention to preventive medicine.

It is clear that all this will make of the process of parturition in the future a more important event than it has been regarded in the past, and she who is about to bring forth will be treated as one about to go through the perils of a capital operation. This is just what I think ought to take place, and, when it does so, thousands of valuable lives which are now lost will be saved, and thousands of desolate households will be spared the sorrow of losing their female heads.

I am fully aware that, at the conclusion of this paper, more than one speaker will arise and declare that his experience of many years of large midwifery practice, with scarcely any deaths, convinces him that all these precautions are unnecessary, that the process of parturition must have changed its character, or that this magnifying the perils of a simple physiological process is a work of pure supererogation, which will have its day, and then for ever pass away. I will simply say in advance to these speakers that I don’t agree with them, and then quote the language of the Puerperal Fever Committee of the Berlin Obstetrical Society, in pressing the preventive measures of antisepsisurgery upon the Prussian government.

We shall not attempt to portray, from a humanitarian point of view, the anguish which falls upon the numerous families, where the wife and mother, who but just now was radiant with the full bloom of health, has been carried off, just as the family has been increased by a new member, still utterly helpless and dependent upon a mother's care; nor shall we point out what injury is done to the national life of the state by the yearly death of thousands of mothers, and the ruin of thousands of families caused thereby. We may fitly compare the manner in which puerperal fever finds its victims in a definite class of persons, with the losses which are entailed by a great war. Just as, in the latter case, the losses fall exclusively upon the young and vigorous male population, so in the former is the most valuable part of our female youth carried off by puerperal fever; nay, more, the loss which the family and the state suffer in consequence of puerperal fever is more acutely felt than that which in general accompanies war, because the latter concerns usually the unmarried and only just full-grown young men. The loss of an entire battalion of Landwehr is the only one which can be fittingly compared, in the severity of its results and the intensity of distress which it causes, with the ruin which puerperal fever brings with it.

Before leaving this part of my subject, let me in the strongest manner record my protest against the use of intra-uterine injections as a prophylactic measure, except after very severe operations within the uterine cavity, which render the occurrence of septicaemia almost certain. As a preventive measure, to be uniformly adopted, I look upon it as to the last degree rash and reprehensible. The use of a dangerous remedy in combating the results of a dangerous disorder is always admissible, but a resort to a hazardous procedure for a condition in connection with which danger has not shown itself, and may not do so, should be viewed in quite a contrary light.

Treatment of Puerperal Septicaemia.

Let us now suppose that, in spite of every precaution, the specific poison has gained entrance at one of the numerous door-ways left open in the genital tract between the vulva and the fundus uteri; what are the most reliable means now known to us for checking the advance of the septic disorders which are set up in consequence?

But let me stop here, before answering the question just asked, and explain what I mean by the use of the term specific poison. I do not believe that there is, necessarily, any specific disease germ which gives rise to puerperal septicaemia! It is probably the same germ as that which is the source of septicaemia, phlebitis, and lymphangitis in the stumps after an amputation, in the wound created by a compound fracture, or in the lacerated tract produced by a gunshot. But the pathological condition excited appears to me to be entirely different from that putrid absorption which results from the decomposition of a retained placenta, or a putrid mass of blood. Such decomposition produces a toxæmia, violent and dangerous it is true, but which disappears as soon as the offending mass is removed. That of the true puerperal disease at once, or almost at once, dis-

cases the lymphatics and sets up an action which often proves uncontrollable. If the mere presence of decaying animal material in a uterus would produce puerperal septicaemia without the agency of a specific disease germ, we should surely have that affection developing in healthy country localities where the women are attended by ignorant midwives, but where, nevertheless, it is almost an unknown disorder.

"I," says Hervieux, "who write these lines, declare that in my own country I have within the space of three years attended one thousand cases of labor, and out of that number have lost only one patient!"

And now, in summing up what I esteem the most certain and the most rational treatment of the disease styled puerperal fever, I will be as concise as possible.

As soon as the patient is stricken by the poison, certain very marked phenomena usually develop themselves with great promptness. After a chill or a slight horripilation she is affected by a high temperature, pelvic pain, considerable mental perturbation, headache, pain in the back, and sometimes, though not commonly, by nausea and vomiting. We will assume, first, that the attack is a severe one in its inception; and, second, that the patient is in such a position in life that we are not in any way hampered in our efforts to save her by considerations of economy. Having considered treatment from these standpoints, it will, of course, be easy to modify the plan so as to meet the requirements of a mild attack or of a scanty purse.

As the practitioner sits by the bedside of his patient at the commencement of her attack, he is aware that there are points connected with its true pathology which he can not yet determine. For example, he can not say whether the case is going to assume the form of septicaemia lymphatica or septicaemia venosa; whether of perimetritis or parametritis; or whether thrombosis of some of the large pelvic or utero-ovarian vessels or a true parenchymatous metritis is to play the most active part in the siege which has begun. If he fritter away the golden moments in vague speculation; if he soothe his fears by hoping that the attack is due to malaria or milk fever; or, if he cast aside the rational doctrines of to-day in favor of the idea of a general infectious and particular form of disease called by the forefathers of the French school "la fièvre des femmes en couche," time will be lost which can never be regained. If, on the other hand, he is encouraged by his clinical observation to stand with many of the best pathologists and practitioners of our time in the position assumed by Hervieux—"I believe in the multiplicity of the affections clasped under the head of puerperal fever; I believe in puerperal poisoning as the source of them"—he will act at once and strike at the poison before it has fairly gained a foothold. In other words, if the physician could see into the future and learn with certainty that peritonitis, cellulitis, thrombosis, lymphangitis, or true phlebitis is to be the final disorder, he should, if he reaches the case at the inception of the attack, follow, in my opinion, the course here formulated:

1. As soon as a diagnosis of septicæmia is determined upon, all pain, nervous perturbation, shock, and mental anxiety should be quieted by the hypodermic administration of ten minims of Magendie's solution of morphine, un-

THOMAS: THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.

655

less some special and very decided idiosyncrasy with reference to opium be ascertained to exist; and throughout the severity of the attack, whenever suffering of mind or body occurs (perhaps it will be about once in every six or eight hours), this should be repeated. In my experience, no other method of administering morphia in these particular cases compares with this, and, as it is not to be continued long, there is no fear of causing the patient to become addicted to the drug as a vice. If a small, sharp, and new needle be used, if it be thoroughly cleansed with soap and water before each time of using, and be dipped in a solution of bichloride, 1 to 1,000 of water, just before each insertion, no abscess will occur. It is the large, rusty, unwashed, and unpurified needle, which the doctor's economy makes last him for many months, which so commonly results in them.

2. The physician must now decide whether, in his opinion, the sepptic disease which is developing has originated in the wounds situated between the os internum uteri and the vulva, or in the endometrium, above the former point. If he decide in favor of the former view, he should persist, for a time longer, in the more thorough use of vaginal injections; if of the latter, intraperitoneal injections should be at once resorted to. Usually the question has to be decided by the efficacy or inefficacy of frequent germicide vaginal injections in bringing down the temperature and controlling other grave symptoms. Should a failure of these seem to prove that the origin of the disease is higher up the genital tract, more decided and radical measures must be taken.

The patient having been entirely relieved of pain and thoroughly quieted, the first injection should be practiced in this way: An India-rubber cloth should quietly, without hurry, noise, or disturbance on the part of the nurse, be spread over the edge of the bed on which she lies, and made to fall into a tub of warm water rendered antiseptic by the addition of 2 or 2½ per cent of carbolic acid, or of the bichloride of mercury, 1 to 2,000, or of some other reliable germicide. Then Chamberlain’s glass uterine tube, which I here show, or the very excellent and ingenious tube invented by Dr. George H. Lyman, which is here seen, thoroughly fitted to a Davidson’s or Higginson’s syringe, should be immersed in the tub. The nurse now aiding the patient by the shoulders, and the doctor by the hips, she should be gently laid across the bed and be made comfortable with a pillow under the head. Each foot should rest upon a chair placed at either side of the tub, and she should be entirely covered over with a couple of blankets. The doctor, now placing himself between the knees of the patient, should take the tube in his right hand, while a stream of water is made to flow through it by the nurse, who squeezes the syringe bulb; and he should pass it gently up to the fundus of the uterus. The stream of water, which has been steadily flowing, is now projected with gentle force against the walls of the uterus, washing away adherent blood-clots, detaching portions of hanging membrane, and everywhere neutralizing the influence of the poison which has excited the disorder.

After the first injection, the position of the patient need not be disturbed, but the injections may be given as she lies upon a bed-pan.

In some cases, in which I have had reason to suspect that portions of the placenta or membranes have been retained, I have chloroformed the patient, passed the hand, rendered thoroughly aseptic, within the cavity, and very gently scraped off adherent masses from the uterine walls, using the nails as a curette, as Wilson, of Baltimore, has advised. In some other cases I have rubbed the whole endometrium with an aseptic sponge, held in a long spongeholder, or employed the largest of my curettes, to remove clots and adherent secundines, with great apparent advantage.

That the use of antiseptic uterine injections after parturition is attended by danger is beyond question. The greatest hazard attending this plan is the entrance of air into the uterine cavity; the next, the production of hemorrhage by detaching some of the thrombi which fill the mouths of the uterine sinuses; the third, the danger of forcing the fluid used as an antiseptic directly into the general circulation, through the introduction of the tube into the mouth of a sinus; the fourth, the creation of convulsions, violent pain, or nervous prostration, by a sudden and baneful influence upon the nervous system; and the fifth, the passage of the tube into a Fallopian canal, and the injection of fluid directly into the peritoneal cavity, as in a case reported by Dr. W. Gill Wylie in an interesting paper in the “New York Medical Journal” for June 23, 1883, p. 670.

All these dangers may be, to a great extent, avoided by care as to details: by using a large injecting tube which can not enter an open-mouthed sinus; by using water warmed to 105°; by injecting the fluid through the tube so as to exclude air before passing this up to the os uteri; by using only a moderate degree of force in throwing the jet against the uterine walls; and by proceeding with the whole affair gently, cautiously, slowly, and intelligently.

The tube should never be allowed to fill the os uteri completely, so as to prevent the escape of the injected fluid. Should the cervical canal be so narrow as to hug the tube closely, it should be dilated by dilators of hard rubber, by the fingers, or by Barnes’s bags, before the injection is practiced.

A solution of the persulphate of iron should always be at hand in case of sudden hemorrhage from displacement of a thrombus. Should this accident occur, ergot should be immediately given hypodermically, the iron solution be at once added to the antiseptic solution and allowed to pass into the uterus, and pressure be made upon the fundus so as to stimulate the contraction of uterine fibers to accomplish closure of the open sinuses in that way.

Quite a number of cases of death from this plan of treatment are on record. In a very large experience with it I have met with but one. The whole number on record would, however, fall, I think, into insignificance if weighed in the balance against the many deaths which have been due to a neglect of the means, or against those lives which have been saved by it.

After all, the question as to the dangers attending a plan of treatment are not to be settled upon mere abstract reason-
ing. The evil which it is known to do must be weighed in one scale, and the good which it Effects in another; and careful consideration must decide whether we are justified in accepting the former for the sake of the latter. Judged in this manner, I feel very sure that intra-uterine injections for puerperal septicæmia deserve a place among the most valuable resources for the saving of life for which we are indebted to modern pathology.

The frequency of these intra-uterine injections should vary greatly with individual cases. In mild cases of septicæmia, where the temperature comes readily down after the uterus has been washed out, and rises very slowly, they need only be used once in every five hours; in other cases they become necessary once in every three hours; and in bad cases they are required once every hour. These injections should always be administered by a physician, should always be carried fully up to the fundus uteri, and should always be used with every regard to caution as to detail which has been already mentioned.

Many prefer the use of those syringes which allow of a steady flow of a stream of water, propelled by gravitation, as is the case with the so-called fountain syringe, which is so popular among us. This is partly because greater safety is supposed to attach to these, and partly from a theory that danger attends the propulsion of a stream by intermittent jet against the uterine walls. For a number of years I shared this belief, but experience has taught me that a gentle projection of the fluid is an advantage, that by this means a more thorough cleansing is accomplished, and that with due caution no more danger attends the plan than that by the steady flow.

Some have adopted continuous irrigation of the uterine cavity, but this is, I feel perfectly certain, a delusion and a snare. It gives the appearance of great thoroughness, which it does not possess, for the reason that by this plan it is very difficult to bring the germicide fluid into full contact with the entire endometrium. For vaginal irrigation it is an excellent method, but I have seen it allow the temperature to remain high when applied to the uterine cavity, and have replaced it by the intermittent douche, used only as often as every three hours, with striking results. Nevertheless, in very severe cases I prefer to employ continuous irrigation, replacing its use every third hour by that of the intermittent current; rather than exhaust my patient by half-hour disturbances and injections, as has been by some advised.

After all that has been said on this subject, the essential fact is this: that plan is best which accomplishes most perfectly the cleansing of the parturient canal. With ordinary precautions, danger need not necessarily attach to any method.

3. The uterus having been thoroughly cleansed, and the patient entirely quieted, attention should be turned to controlling the temperature, which, in septicæmia of puerperal character, runs so high and maintains itself at so excited a range as to constitute one of the immediate factors of a fatal issue. Even if this were not the case, the patient's strength is so much exhausted by prolonged high temperature, her nerve power so much depreciated, her blood-state so rapidly injured, and her comfort so decidedly interfered with, that these considerations alone would point to the propriety of combating hyperpyrexia. For this purpose I formerly relied upon the infusion of cold, or tepid water, the patient lying upon Kibbee's cot; at present I accomplish the same result more easily and more pleasantly for the patient by the use of Chamberlain's rubber-tube coil, which I here show. A mat, composed of a rubber tube rolled upon itself in a circle, covers the whole abdomen from the ensiform cartilage to the symphysis pubis; the upper end of the tube which makes this mat is anchored by a weight in a tub of ice-water, placed about three feet above the level of the patient, and the lower end falls into a tub upon the floor. By siphon action the water of the elevated tube runs through the tube which constitutes the mat, and collects in the receptacle on the floor. By this means a temperature of $104^\circ$ can very readily, as a rule, for there are exceptions to the rule, be kept at $106^\circ$ for weeks together.

Unfortunately, there are almost insurmountable difficulties connected with the use of this invaluable method in the minds of the patient's friends, the patient herself, the nurse, and alas, too often, the attending physician. You are told that the patient becomes chilled, that the coil prevents her resting, that the temperature absolutely goes up under its use, and descends whenever it is left off; and by the doctor you are apt to be informed that his fear of resulting pleurisy, bronchitis, or pneumonia is very great.

I will merely say, in refutation of these charges, that in my service in the Woman's Hospital, where convalescents from laparotomy are constantly under treatment in large numbers, this means of controlling temperature is as commonly and as freely in use as poultices are in general hospitals, or gargles in dispensaries for diseases of the throat. We never meet with any of these difficulties, and very rarely with failures as to the desired result, and I believe that I am correct in saying that successive house-staffs, whose duty it has been to carry out the plan, have thus far had, to a man, the most implicit faith in its beneficial agency.

There are some peculiarities about it, however, which I must mention. Very often the coil will not succeed in controlling the temperature for twenty-four hours; its prolonged use alone develops and illustrates its great benefits; and removing it from the body for an hour at a time damages its influence very much. I have never seen evil result from the chilliness which it excites, if hot bottles be kept at the soles of the feet, and in not one instance, out of hundreds of cases, have I seen pneumonia or pleurisy excited by it.

4. The nervous system should be so kept under the influence of febrifuge medicines as to keep under control the tendency to chill and pyrexia. For this purpose, fifteen grains of the sulphate of quinine should be given in capsule or by suppository night and morning, or, in place of this, two capsules may be given night and morning of Warburg's tincture, in the form of solid extract, as advised by Dr. J. T. Metcalfe. Lastly, to the same end the salicylate of sodium may be employed.

5. The patient's diet should consist entirely of fluid food,
THE SO-CALLED PINK EYE
AND HORSE SCARLET FEVER.

By JOHN C. PETERS, M. D.,
NEW YORK.

Some years ago I met with allusions to scarlet fever in horses in some French medical journals which arrested my attention, and, as I was then engaged in attempting to improve the sanitary condition of stables in this city, I at once made inquiries about the matter in some of the large livery, car, omnibus, and sales stables. An epidemic of so-called "pink eye" was then prevailing. I had seen the disease before. Almost all horsemen agreed that this distemper had many varieties, but was not infectious or contagious, and was generally produced by exposure to cold and wet, aided by some peculiar "constitution of the air" and hard condition of the stables, which predisposed to epidemic disease. It was thought to be a catarrhal-rheumatic affection, but I was struck with the degree of sore throat which existed, in some cases in connection with swelling of the glands of the neck, rheumatism, and dropsey of the legs. I did not then know how to look for the eruption upon the skin, or in the nostrils, mouth, and throat. I was told that almost every affection of the nostrils and throat in horses was apt to be attended with swelling, and even abscess of the glands of the neck, while the exposure of the backs of horses to cold and wet was so often followed by renal troubles and dropsey of the legs that no diagnosis of scarlatina could be based upon any or all of these indications. These explanations seemed so satisfactory that I did not examine the works of the English and American veterinary writers, but let the whole matter drop until Dr. Stickler's article appeared in the "Medical Record" of March 24th of this year, 1883.

I then looked over all the books on veterinary medicine in the Astor, New York Hospital, and Academy of Medicine libraries, and found almost overwhelming testimony as to the existence of scarlet fever among horses, commencing with Percival's account in 1834. It is well to state here that Percival's work on hippopathology is still read at the present day with almost as much interest and profit as Sir Thomas Watson's "Principles and Practice of Medicine," first published in 1836-37. Percival was also one of the first editors of the London journal of veterinary medicine ("The Veterinarian"), which is continued to the present day. Percival was followed by Surgeon Haycock, Edinburgh, 1850; James White, London, 1851; by Copland in the "Medical Encyclopaedia," 1859; Dadd, "Modern Horse Doctor," 1866; by Armitage; and ultimately by Williams, of Edinburgh, 1876; and Robertson, of London, in July, 1883. I also looked over Fleming on "Animal Plagues"; Basham and Webster on "Epidemics"; Theophilus Thompson on the "Annals of Influenza"; Hecker's "Epidemics of the Middle Ages"; and the whole series of the "Veterinarian," from 1830 to 1883.

These researches convinced me that various diseases of animals, communicable to man, and vice versa, had prevailed again and again; among them angina maligna, undoubted diphtheria, and both scarlatina and true measles, and, in all probability, that hybrid of the two diseases which is so well
described in Aitkins "Science and Art of Medicine," vol. i, p. 345:

I then commenced my researches anew for the discovery of scarlet fever among horses in this city. The surgeon of the Fourth Avenue stables told me that he had had cases which he would have liked to submit to the examination of experts, but knew not where to apply. The Third Avenue car stables, with two thousand horses, is under the care of a homeopathic veterinary surgeon, who is familiar with the disease, and referred me to a short but excellent description of scarlatina in horses in Pulte's "Manual." The foreman and physician of the Sixth Avenue car stables had been acquainted with scarlet fever in horses since 1869, when he was instructed in its diagnosis by the late Dr. Copeman, a veterinary surgeon of good repute at that time: he had had three cases quite lately. Several of the proprietors and surgeons of the large sales stables were conversant with a disease marked by inflammation of the eyes, nose, and throat, and with an eruption upon the skin which they were in the habit of calling measles, as it resembled a similar disease which they had seen in their own children. It differed from ordinary colds, catarrhs, and influenzas: and, when their attention was called to the frequency with which glandular swellings and dropsy attended the disorder, they were quite willing to admit that some of the cases might have been scarlet fever, or a hybrid of measles and scarlet fever.

Professor Leautard had seen but few cases during the last twenty-two years, and then only in the purpuric form, which he doubted being true scarlet fever. Professor Bates, of the Columbia Veterinary College, was familiar with it in its true, undoubted, and uncomplicated form, and not only loaned me many books, but referred me to Dr. F. Walton, who wrote out a description of it for me, from his own experience with it, as follows:

DEAR DOCTOR: I have observed equine scarlatina in stables especially along the river fronts, more particularly during the prevalence of the disease known as "pink eye." This name covers multitudes of ignorances, and is applied to several different morbid conditions, but I have thought that some of them were epidemics of pure scarlatina. In that variety of pink eye to which I have given the name of equine scarlatina the onset is sudden, the invasion being characterized by much prostration, and a temperature running up rapidly until the fifth or sixth day, varying from 104° to 106°, and even 107° F. It is certainly contagious, for other animals fall sick in the stables within four days after the first appearance of a case in a previously unaffected building; and I have noticed that those animals which have already had the disease do not succumb to it a second time. There is an eruption on the skin, which in some animals only looks like an erythema, or congestion; but the mucous membranes of the eyes, nose, mouth, throat, and ears are covered with a distinctly characteristic red (or scarlet) rash, generally confluent, but often punctate, and sometimes blotched. There is a free catarrhal secretion from the nose and eyes, but finally the mucus surfaces of the mouth, tongue, and fauces peel off, leaving a raw, looking surface (like the strawberry tongue of scarlet fever). The fever continues till the fifth or sixth day, then gradually subsides, and generally wholly disappears by the ninth to the eleventh day. Sequela are apt to appear within ten days to three weeks, marked by drooping swellings, frequently, when albuminous urine is almost invariably present. Sometimes we have a general rheumatic joint affection, which finally disappears spontaneously. Subacute pleurisy is the worst complication or sequel. In one case I had a decided ctitis media, followed by total deafness. Young horses take the disease more frequently than older animals, although the latter are not always exempt. The trouble is self-limited, and frequently mild, so that palliative treatment is all that is required. Through the kindness of Dr. W. Oliver Moore, a committee man, I obtained the opinion of Dr. R. W. Finlay, of Harlem, who had observed about six hundred cases of "pink eye," in stable parlance, or equine scarlatina. He says: "The urine is scanty and slightly albuminous on the second day, in many cases, and the temperature rises to 105° to 104° F., with slight droops and symptoms. On the third day (scarlet) petechial spots are visible on the nasal mucous membrane; the pulse is 60 to 80 per minute, 40 being normal in the horse; temperature 104° to 106°; with tenderness of the glands, and difficulty of swallowing, so that very little food can be taken. On the fourth day the droops have increased, and the temperature rises to 107°, or even 108°. On the fifth and sixth days the spots on the nasal membranes are of a deeper hue, the urine highly albuminous in some cases, and tinged with blood in a few. On the seventh day improvement generally commences with a slight desquamation beginning in the ears, but the disorder seems most contagious then. Adenitis, when present, usually shows itself between the ninth and fourteenth days, and is attended with the usual signs of pus forming in glandular structures."

In the London "Veterinarian" for September of this year I have found an article on pink eye, by the veterinary surgeon of Bardett-Coutts, Esq., which not only says, but proves, that it is contagious and generally attended with an eruption of the skin, usually on the quarters; that crescentic and moniliform bacilli are found in the blood and secretions; and that inoculations with the blood, tears, and nasal mucous have reproduced the disease. Pink eye was thus conveyed from a partly blooded horse to a cart-horse; from that to Guinea-pigs, and from them to a pony; so that there can no longer be any doubt about the contagiousness of the disorder, which is denied by most veterinary men.

Dr. J. N. Stickler, of Orange, N. J., has successfully inoculated two colts with human scarlatinal virus. Dr. Fenner has seen cases of scarlet fever in horses in his own practice. Dr. Lyon reports a well-marked case of a gelding, eight years old, with enlarged submaxillary glands, sore throat, and high temperature—105° to 106°. On the next day the hair and skin of the neck, face, and shoulders were elevated by an eruption, the soreness of the throat increased, and a bright scarlet eruption was noticed on the septum nasi, followed by a muco-purulent nasal discharge. After the eruption had entirely receded, the skin began to desquamate, and the groom could scarcely make his coat presentable. Drooping swellings of the legs and sheath occurred afterward.

The Medical Register for New England.—It is announced that a new edition of this publication will soon be issued by Messrs. Copples, Upham & Co., of Boston. It will contain much new information, carefully compiled by Dr. Francis H. Brown, whose endeavor has been to make it of every possible assistance to those engaged in the medical profession. The book will be published at a lower rate than in previous years, and doubtless every physician and surgeon in New England will avail himself of a manual so essential in his work.
SOME NOTES ON COMPARATIVE PATHOLOGY.

CANCER IN DOMESTICATED ANIMALS.

By W. H. BIRCHMORE, M.D.,
CARBONDALE, KANSAS.

At present, when the relations between the diseases of man and his dependent cousins are being realized and brought to notice, and influencing many minds for their advancement in learning and to the broadening of their field of view, an account of cases such as the following needs no apology for intruding itself on the time of the thinking portion of the medical profession. Their clinical interest is not so certain, but a priori it may be questioned if the food from animals in whose bodies degraded material processes are going on can be any more edifying than the mental pabulum of the same description is by some held to be. If the existence of a mammary cancer in a woman would, in the judgment of a thoughtful practitioner, be good cause for doubting the advisability, surely the existence of cancerous ulceration in the udder of a cow would be good cause, for the disallowance of the use of her milk for the food of young children.

The investigation whose results this paper offers was undertaken to obtain material for the inflammatory origin of tumors. But time went on its way, the paper was never written, and now it is offered as a contribution to the general stock-in-trade of the pathologist. Its intrinsic interest is not lessened, even if it is regarded as a curiosity only; but it also indicates that, besides enteric fever, pneumonitis, and tuberculosis, another vice of nutrition is shared by us all.

Case I.—A chicken whose humerus had been broken. Three months after, a lump the size of an egg was present. In the center of this mass the united fracture could be perceived. Death followed from exhaustion after some months. The lump was a very finely developed, large, round-celled sarcoma. The cells were in nests proliferating, some multinucleated. There was no proper callous formation, but the ends of the bones were swollen, softened, and covered with the cell-deposit. The lymphatic glands were not inflamed. The tumor weighed 64 grammes.

Case II.—An old hen. Feet frost-bitten. A piece of superficial tissue about two centimetres in diameter came away from one foot. The resulting sore was treated with the compound tincture of bezoain and fresh lard, equal parts, made into an ointment. The right foot healed completely; the left nearly so. This hen hatched a brood of chickens in the spring. The next time I noticed her, about midsummer, she was moving in so peculiar a manner that I caught her, made an examination, and found the left sole occupied by an elastic mass of about the size of a pigeon’s egg. The leg soon became useless, and the hen died marasmic. On post-mortem, I found the lymphatic glands enlarged, containing multinucleated cells, the stroma proliferating pari passu. The extremity of the tarso-metatarsal bone was a mass of eenchephaloid disease.

Case III.—A capon. I removed the glands by the usual operation. The capon died, at the end of three months, of acute peritonitis. He was as large as a turkey. The post-mortem showed that the peritonitis was caused by the bursting of a cyst containing some irritant fluid, which cyst formed part of a tumor as large as an egg, occupying the place of the right testicle. This tumor was an adenoid sarcoma. The size of the tumor was remarkable in view of the capon’s development.

Case IV.—A fine setter. Wounded in the mouth by the discharge of a gun. The canine tooth on the lower jaw, right side, was so loosened as to be disengaged by very gentle handling. Ulceration of the socket followed, and after a considerable period a tumor grew, whose size made the dog so miserable that he was allowed to die. The microscope sections thereon obtained might have served as originals for the drawings of osteo-sarcomas shown in the books.

The next four cases of which I have memoranda were in horses and mules, the result of injuries from the abuse of bits. In one of them there was an exostosis, or else a sub-nuchous thickenings of the roof of the mouth. The animals were otherwise in good condition.

My next was a large, mixed spindle and round-celled sarcoma from the lower lip of a male, caused by the irritation of the bit.

Case X.—A papilloma, irritated by the rubbing of the bridle behind the ear of a horse, became ulcerated. I removed it and obtained some excellent sections of a connective-tissue tumor, with nests of pseudo-epithelial cells.

Case XI.—Last spring, while visiting a patient, I learned that one of his cows was “snake-bit.” Investigation showed an ulcerated mass on the udder that macro- and microscopically answered to a nodulated mammary cancer.

A case of a gastric tumor in a pig was offered at the Chicago meeting of the American Society of Microscopists. Epithelial tumors at the point of the shoulders in abused horses are not very scarce.

Engorgement of the lymphatics of the base of the tongue following wounds that healed by leaving an indurated cicatrix have passed under my notice; also one case of a lump, of the size of a fist, that formed about the parts pressed against by a ring in a bull’s nose. There was nothing destructive about this tumor, but its evident inflammatory character renders it worth mentioning.

Villous tumors of the intestine are not infrequently found in hogs.

The fact that lymphatics may swell and become indurated in pigs as the result of dysentery, and then present a very suspicious appearance under the microscope, opens a field that needs further investigation. From my own study in this direction, I am inclined to the conclusion that, as all nutritive processes as a rule are more rapid, and healing processes are more complete, in the lower animals than in mankind, interruptions and maldirection of these processes are productive of less disastrous results. Still there is evidence to be found among them, and among them alone, that makes the modus vivendi of the tumor brotherhood much clearer than in man. In dumb animals only can we find very young growths and remove them at our will, or remove all the neighboring tissue and appreciate its relations.

Any persons knowing of similar cases will confer a favor
by sending descriptions and either drawings or sections showing the microscopic anatomy. Specimens, where they can be obtained in masses of one cubic half-inch, will also oblige. There is need of much more knowledge than we have in relation to these troubles—their aetiology—and the only way of obtaining it is by the study, not of books, but of the things themselves.

CASE OF
SLOUGHING IRREDUCIBLE HERNIA;
SPONTANEOUS RECOVERY.

By A. D. Decker, M. D.,
Pleasant Plains, N. Y.

Mrs. D., a widow, sixty-six years of age, of previous good health, but habitually constipated, was seized, during the evening of April 12, 1883, with violent abdominal pain, nausea, and vomiting of bilious matter, which continued for three days. Cathartic medicines failed to act on the bowels, and on the 15th a large enema was given. This produced a free evacuation of scybalus. She then improved until the evening of the 17th, when the pain, nausea, and vomiting returned with greater severity than before. On the morning of the 18th she vomited stercoraceous matter containing a lumbricus, and a severe diarrhoea set in, accompanied with much pain. These symptoms were controlled by opium, but in the afternoon she was distressed with a burning sensation in the abdomen; the skin was cold and clammy; the pulse 136 and very weak; and the tongue coated.

At this time a swelling was discovered in the right groin, about two inches long and an inch wide. It was inflamed and tender. She stated that she had noticed a lump in that situation at times for several years before, but had never felt any inconvenience from it.

On the 19th and 20th there was no nausea nor vomiting, but she continued extremely prostrated; the coldness of the surface continued, the pulse was 144 and very feeble, and the tongue was coated. The swelling had grown larger and was more tender. The burning sensation in the abdomen was relieved by the action of an enema.

From the 21st to the 24th her general condition improved, but the swelling continued to increase in size and to become more tender. The burning sensation also continued.

On the 25th the pulse was 136, and the temperature 99.5° F. The tongue was dry. The bowels moved spontaneously.

On the 26th the pulse was 144, and the temperature 99.75°. The swelling was still larger, and had become tympanitic. It was punctured with a hypodermic needle, and considerable gas escaped, giving the patient some relief.

On the 27th the pulse was 148, the temperature 101.75°, and the tongue very dry. A circular gangrenous spot two inches in diameter appeared on the lower part of the swelling. The bowels acted spontaneously.

On the 28th an opening formed through the gangrenous spot, communicating with the interior of the intestine, and giving exit to pus and faecal matter, together with a lumbricus. Two more spots of gangrene, half an inch and two inches in diameter, appeared above and to the outer side of the first spot. The patient felt relieved; the pulse fell to 136, and the temperature to 99.5°. The bowels moved spontaneously.

On the 29th she continued to improve, and took food freely. The pulse was 130, and the temperature 99°. The tongue was cleaner and more moist. Two more gangrenous spots appeared to the right of the pubes, also a bleb on the right labium majus. When opened, the latter discharged thin faecal matter, and exposed an opening, a quarter of an inch in diameter, the termination of a fistulous canal running from the sac above.

Up to May 6th the patient improved gradually, faecal matter being discharged freely from the openings. The gangrenous tissue had now all separated, but an ulcer was left, six inches long by two inches wide, extending from the pubes upward and outward beneath the crest of the ilium, discharging an ichorous matter. A nitric acid lotion was ordered, and the discharge was soon changed to laudable pus. From this time on there was no further escape of faecal matter from the abnormal openings. The fistula leading to the labium was closed by the 4th of May. Convalescence was interrupted by impaction of the colon, which was relieved by a large enema thrown high into the bowel. By the middle of June the patient was able to sit up a portion of each day, and at the end of the month the ulcer had healed. By the 1st of November she walked about with the aid of a cane.

Clinical Reports.

VIENNA POLIKLINIK.

CLINICAL REMARKS IN THE COURSE ON GENITO-URINARY DISEASES.

By Dr. Robert Ulltitzmann,
Privatdocent in the University.

Stricture of the Urethra.—Hypertrophy of the Bladder.—Urethral Fever.—Chronic Urethritis.

Case I.—On questioning this patient, we learn that he is fifty-three years old, and that during the past twenty-five years he has had trouble in passing his water. Here we have two things to remark—in the first place his age. He is fifty-three; hence the bladder is probably weak, and not able to empty itself entirely, and this condition is doubtless due to an old stricture. In such a case as this it is not enough to examine the stricture, but we must also investigate the bladder. This man has been under treatment more or less for twenty-five years, which proves that it will not be sufficient to simply dilate his stricture. And in this connection I would say that it is not the fact that the urethra will only admit a No. 12 or 14 English. For it is much wider. We often notice in cases of median lithotomy that the forefinger can easily be passed into the bladder through the posterior part of the urethra. As regards the anterior portion of the urethra, we find that we can use very large instruments if only the meatus be first slit. In upward of sixty lithotriplies I have found no difficulty in passing a No. 28 into the bladder. But this condition becomes changed when once
the canal has lost its elasticity, a result most often produced by gonorrhoea. When we remember how rich the nervous supply of the urethra is, we can understand how the irritation caused by a urethritis can give rise to constriction. The natural elasticity of the outlet being lost, the urine can not escape so readily, hence a resulting hypertrophy and dilatation of the bladder. The urethra may become contracted to two thirds of its normal caliber. Think how hypertrophied the bladder must become in order to overcome this resistance! In a young, strong man this change may be so slight as not to be noticed, but in an old patient the bladder speedily becomes affected. The presence of hypertrophy is easily recognized. Any one who has never made an examination before can readily feel trabecula by sounding, and the existence of trabecula means hypertrophy. It is of primary importance to decide if the bladder is able to empty itself completely. If a small amount of urine, only a few cubic centimetres, remains after urination, it shows that the organ is weak. In such a case the patient must use a catheter constantly in addition to having his stricture dilated.

A patient who at twenty or thirty has a residue of only twenty c. c. remaining in the bladder, after urinating, will have from two to three hundred c. c. at fifty, with an accompanying hypertrophy.

In the present case there is a history of attacks of fever following the introduction of instruments. Now, fever is so frequent a phenomenon after the use of sounds that it would be quite erroneous to argue from it that a false passage had occurred. It is doubtless of nervous origin, and may be observed after the forcible dilatation of the vagina or rectum. We frequently see a patient, before in perfect health, suddenly seized with a violent chill after sounding. This may be often repeated, and is sometimes so severe as to shake the bed. It is simply a reflex chill, due to the stretching of the urethra. This is the beginning of so-called “urethral fever.” It is not right to regard it as due to any inflammatory process, since it is usually unaccompanied by any trace of mechanical injury.

Now, to proceed with the examination of this patient. First of all, I always examine the prostate through the rectum. I find that it is not much enlarged. Now I shall try the urethra, using first a good-sized instrument (Charrière, No. 22). It is arrested in the anterior portion of the canal. A No. 19 stops at the same place. No. 17 goes in perhaps a centimetre farther, and it seems as if the instrument had entered a narrow passage, at the end of which it is again stopped. With a No. 14 I can press on as far as the bulb, but here it is firmly grasped, and can not be easily withdrawn. With a conical sound (No. 12) I can pass this obstruction also, and reach the bladder, which seems to be thickened and trabeculated. I have done enough for today, and shall have the patient return next week, when we shall commence the treatment regularly.

Case II.—This man has a chronic urethritis. We say that a case of gonorrhoea is acute when it runs its course in from four to six weeks, and we say that it is cured when the discharge has ceased. But, by examination with the endoscope, we can readily see that the mucous membrane is still covered with a secretion, which is washed away during micturition, and therefore is not noticed. Most of this secretion is really a kind of false membrane developed on the mucous membrane of the urethra, and has no connection either with the prostate or with Cowper's glands. When the disease is acute, this secretion is very copious; when it becomes chronic, there are only a few epithelial scales, which come away in the urine. Microscopical examination sometimes shows the presence of semen in the discharge, and nocturnal pollutions may accompany a urethritis affecting the deeper parts of the canal. It is not easy to tell whether the anterior or posterior part of the urethra is affected from an inspection of the secretion alone. In general, that from the posterior portion is thicker and more stringy.

This patient has passed his water, and you will observe in it small, stringy masses. Since they are so small and scattered, there are probably only a few inflammatory spots in the urethra. Where is the urethritis in this case? Undoubtedly in the anterior portion, since the patient experiences no pain during micturition. If the pars prostatae were affected he would have pain at the end of the act. What is the treatment? Chronic urethritis causes changes in the urethra. Have we evidences of thickening or stricture in this case? Can we pass a No. 24 or 26? If we find a stricture, we must proceed to dilate it at once. The second thing is to apply local treatment to the seat of inflammation. This may be done with an ordinary syringe. In acute gonorrhoea it is not only unnecessary, but positively injurious, to employ too large injections. It is better to use only half a syringeful at a time, and to repeat the injection two or three times. Nothing can wash away the secretion so well as the stream of urine, so that it is a good plan to have the patient pass his water just before making the injection. With very few exceptions, the narrowest strictures will occur in the bulbous portion, so that in obstinate cases of urethritis we must apply our medication directly to the deep part. This will be difficult, as the bulbary muscles respond quickly to any irritation, and will force out the irritating fluid. It is important to make the applications directly, which can be done through a catheter or a syringe constructed expressly for the purpose. A small, thin catheter (No. 7) will be most convenient. Introduce it slowly to a distance of twelve or fifteen centimetres, until a hindrance is encountered. This is due to the contraction of the muscles. Inject slowly 200-500 c. c. Do this once a day, and you will meet with a speedy cure. The solution should always be warm. I use the following:

1) Alumunis, zinchi sulphat., ac. carbol. pur., a 1:00; aqua destill., 500:00.

This may be diluted as much as desired. Increase the strength of the solution every day until it reaches four grammes of each ingredient. Or you may employ:

2) Potass. permanganat., 2:00; aqua destill., 200:00.

Add 10:00 of this to a tumblerful of warm water for each injection. You can increase this gradually up to 50:00. Finally, a third solution is:

3) Argent. nitritis, 1:00; aqua destill., 500:00.

In the case of this patient I shall introduce a catheter to the end of which is attached a long rubber tube, and you see how easily the injection may be made by means of an ordinary hard rubber syringe: indeed, the patient can readily be taught to do it himself. In the present instance I can find no stricture, though the anterior portion of the urethra feels as if it were thickened.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

CLINICAL REMARKS BY ALFRED C. POST, M. D., LL. D., EMERITUS PROFESSOR OF CLINICAL SURGERY.

Case I.—Gentlemen: Before proceeding to do the operation announced for to-day, I present before you a patient with an adenomatous or glandular tumor of the neck. The tumor
has existed now for about two years, was until recently hard to the feel, and had been increasing in size. About four weeks ago the patient came under the care of the physician who has brought him here to-day, and who commenced treatment by local applications of the olate of mercury. The growth immedi-
ately began to decrease in size and to become softer in char-
ter, thus illustrating very well the resolvent powers of mer-
cury in these cases of scrofulous enlargement of the glands. As
the tumor has evidently been resolved into an abscess, the treat-
ment at present is to let out the matter with the knife. Instead
of making a large opening, as was formerly the practice, and
letting the surface heal by granulation, I propose simply to in-
troduce the point of the knife, draw off the contents, and inject
the cavity with carbolic-acid solution, 1 to 40, according to the
method introduced by the late Mr. Callender, of London. The
cavity is over-distended with the fluid injected, and the proced-
ure is repeated until the solution comes away nearly or per-
fectly clear. It is quite certain that the abscess walls heal quic-
ker by this method than by the old method, in which no antiseptic was used. But there is one precaution to be exer-
cised in the use of the carbolic solution, especially in abscesses
of large size, where the fluid comes in contact with a large
amount of absorbing surface; and that is, the avoidance of tox-
ic effects. In the case of small abscesses, as in the present in-
stance, there is not much danger of such an accident. You will
notice that the pus as it escapes presents a somewhat greence
appearance, and contains flocculi; it is, as in most cases of scro-
fulous inflammation of the glands, not laudable or praiseworthy
pus—if any kind of pus can be called laudable or healthy. If
the coagulated particles block up the opening before the cavity
has been emptied, they can be removed by means of a probe or
other instrument. I would call your attention to the kind of
syringe which I employ. It is made of a hard, black rubber
cylinder, either end of which can be unscrewed and removed;
this the physician, especially if he lives in the country, will find
of advantage, as it will enable him to adjust the piston more
easily, should the instrument get out of order, and save the time
and expense of sending it to the maker. The nozzle is tapering
at the point, so as to adapt it to a larger or smaller orifice.

Case II.—You saw this patient last week, a rather unusual
case of defective formation of the left hand. The index and the
little fingers are wanting; the middle and ring fingers are pres-
cent, and are webbed together. The webbing extends from the
commissure to the last phalanx, near the extremity, where the
two fingers are joined throughout their whole thickness. But
a single nail belongs to the two fingers. Webbing of the fingers
is not a very unusual deformity, but such a combination as ex-
ists here is seldom seen. The normal difference in length be-
tween the ring and middle fingers is apparent, but the ring fin-
ger is straight, while the middle one is bent, the webbing pre-
venting extension. I think that, in a case like this, where there
is a deep groove both on the dorsal and on the palmar aspect,
a simple incision through the webbing and dressing so as to
keep the fingers separate, is all that will be required. In cases
where the fingers are joined throughout their entire thickness,
no groove being present, it is a matter of some difficulty often
to keep them from reuniting after separation. In such a case,
beginning the incision at the commissure, you can make a little
hole, as is done in puncturing the ear, and, at a later period,
after the opening has been lined by integument, complete the
division with the knife from that point. Some years ago the
late Dr. J. Kearny Rodgers, one of the surgeons of the New
York Hospital, introduced a new method of performing the
operation. He made an incision over the dorsal surface of one
of the fingers involved and over the palmar surface of the other,
and dissected up the dorsal flap to cover the side of one finger,
CASE III.—About five weeks ago this boy was cut upon the dorsal aspect of the index finger transversely near the first phalangeal joint. Since then he has not been able to extend the finger, although I am able to extend it for him with perfect ease. It is five weeks since the injury was sustained, but, as the use of the finger is of some importance to him, I shall undertake to unite the divided extremitics of the tendon, with the hope that union may take place. Now that I have made an incision of some length along the back of the finger, you will notice that the proximal end of the tendon is somewhat enlarged and tumefied, while the distal end is slightly atrophied. I pare the ends of the divided tendon, unite the two with sutures, dress the wound, and the patient will return from time to time, that we may watch the result.

Book Notices.

No lover of books is likely to pass lightly by this handsome volume, with its thick paper, broad margins, uncut leaves, and large, clear type. The proof-reading has been most exact, and the publisher's part thoroughly well done. The author promises to have a message to deliver, not unworthy of its comely dress—no less than "a new discovery of a great law of Nature; . . . the law which governs the sexes, and whereby the sex of offspring can be controlled." He has studied the subject for twenty years, in various languages, but has delayed publication until he could, "by extensive observation, establish its truth beyond the possibility of doubt."

This great law, which the author would briefly call the law of "superior opposites," is first stated on page 91, as follows: "Sex is determined by what I shall designate as the 'superior parent,' and the 'superior parent' produces the opposite sex;" the term "superiority," he is understood, referring only to those qualities which control functional activity.

It being plainly of great importance that "superiority" should be clearly defined, this part of the subject is treated at sufficient length in Chapter VII and elsewhere. On page 101 it is stated that a "preponderating vital endowment produces the opposite sex." On page 109 it is said to be determined by such characteristic indications as temperament, complexion, will, the reproductive, nutritive, and osseous systems, and by special features. "Every member, feature, expression, or action indicates something either for or against superiority" (p. 125), and each of these indications is taken up and treated of in turn by itself, even to the features of the face. Thus, prominent veins denote superiority; while a drooping eyelid is a sign of inferiority; moist hands indicate excessive lymph; and the quantity of hair in the eyebrow, the shape of the head and forehead, mouth, lips, chin, even the teeth, have each their significance. At one time he thought the nose to be a sufficient guide, having discovered (p. 154) that the more decidedly Roman the father's nose, the larger was the proportion of daughters in the family. But, although the "osseous system is generally manifested in the nose" (p. 124), his "nasal rule" did not quite stand the test of experience, and he was obliged to add as factors a strong will, a ruling disposition, and the fact that daughters of superior fathers determine sons of their own, thus eventually equalizing the sexes. Having once mastered the solution of this sufficiently complex problem of superiority, he finds that he can generally predict at will the sex of the children upon seeing the parents. It is interesting to note that in the course of this study the author has observed that clergymen and physicians (!), and especially orators and musicians, are apt to have a preponderance of sons; so that he now places these classes "in a far lower category than that in which he would at first have ranged them" (p. 166).

Turning to the practical application of his law, the control of sex, he advises (p. 229) the father who desires a son to discontinue intellectual activity and cultivate the body, while the mother subordinates the nutritive system. She should study, and "abjure" tea and coffee, while he should cultivate "nerve force" by oily and anylaceous food, and consume more phosphates, in the form of fish and soft-boiled eggs.

The author is furthermore strongly inclined to think that a "temporary superiority" can be secured by temporary measures. If, for example, a daughter is desired, let the father take a Turkish bath and the mother a sitz bath (p. 235). But this is a part of the question into which he hesitates, for obvious reasons, to enter too minutely. In general terms he would say, "Let it be remembered that the basis of superiority is the quantity and quality of nervous force a person is able to command at any given time, and, generally speaking, is in the habit of commanding" (p. 245).

Now, much of this sounds like very poor nonsense, and the scientific reader must needs smile at almost every page. Yet he reads on, and, reading, finds himself unconsciously applying the law to instances within his own experience, and very probably accepting the main points of the theory itself. Before closing the book, which he is pretty sure to read through, he is faint to confess that the hasty first judgment, based upon the defects of the author's style and the haphazard manner in which he has jumbled together facts and opinions from the most incongruous sources, needs revision.

The defects of style referred to are most conspicuous in the ninety or so introductory pages, which the author devotes to discussing and clearing away the very numerous theories that have preceded his own. More than five hundred such theories, he says, were extant toward the close of the seventeenth century, and, although he does not attempt even to name them all, his citations are both numerous and various. Thus, in the four pages from 93 to 99 he quotes from and seems to have read Dubois-Reymond, Galvani, Ashbourne, J. C. Jackson, Matteucci, Böeck, Helmholtz, Schleske, Hemmer, Giardini, Sfösten, Ahrens, Pfaff, Nasse, and Beard and Rockwell. From Darwin to O. S. Fowler and from Hippiocrates to the "Medical Investigator" of Chicago are by no means too abrupt transitions for this omnivorous but too greedy and rapid reader, who delivers his mental insatia unassimilated, instead of taking time to make him his own by digestion and conversion. Therefore, whenever he wanders from the straight and narrow path of his "law," which is simple and intelligible enough, he stumbles among vague notions concerning polarity, odyllic force, electricity, magnetism, and the like bulderdash, dear to untrained speculative minds.

The "law" itself seems to have been suggested by Combe's three laws of heredity: 1. The parents transmit "at the decisive moment" qualities in proportion to their actual power and activity. 2. These qualities combine and may neutralize each other. 3. The mother exercises a powerful modifying influence during gestation. Several cases reported by M. Giron, whom,
BOOK NOTICES.

A System of Human Anatomy, including its Medical and Surgical Relations. By Harrison Allen, M. D., Professor of Physiology in the University of Pennsylvania, etc. Illustrated with Three Hundred and Eighty Figures on One Hundred and Nine Plates, many of which are Beautifully Colored. The Drawings by Hermann Faber, from Dissections by the Author. Also, Upward of Two Hundred and Fifty Wood-cuts in the Text. Section V, Nervous System. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. iv-459 to 683, inclusive.

Description of a Revolving Asymmetric Disc. By Charles A. Oliver, M. D., Philadelphia. [Reprint from the "Medical News."]

Annual Report of the Surgeon-General, United States Army, 1883.

On Photographing the Larynx. By Thomas R. French, M. D., Brooklyn. [Reprint from the "Archives of Laryngology."]

Possible Cerebral Origin of the Symptoms usually classed under "Railway Spine." By G. L. Walton, M. D. [Reprint from the "Boston Medical and Surgical Journal."]
PUERPERAL FEVER.

The Academy of Medicine could scarcely have presented before it a subject for discussion more likely to bring out diverse views, both as to pathology and as to treatment, or more promising to its fellows, than the different morbid manifestations that are grouped under the term puerperal fever. It is very gratifying, therefore, that such a discussion has been opened in the Academy, and by the presentation of such striking views as mark Dr. Thomas's paper, the full text of which is given in this issue of the Journal. Meigs's "good Gordonian bleeder" has doubtless disappeared, at least from this part of the world, but it will be a matter of some surprise if almost every other mode of treatment save Gordon's is not passed in review before the debate is finished; and even that obsolete practice may, with some show of justification, assert that it still lives in its progeny—the antipyretic treatment of the present day.

Of course, the chief value of such a discussion attaches to the practical question of how to manage puerperal fever, but an interest little less vital hinges on the pathology, a matter yet far from settled. So far as the discussion at the Academy has been carried, all the speakers who have expressed themselves on the point seem to have agreed that some form of blood-poisoning is at the bottom of the affection. It can not be said, however, that they are all in accord as to the precise part played by that fundamental factor, or as to its exact nature. The author of the paper made a distinction between septicemia as an element in puerperal fever and that condition which results from the retention of mere decomposing matter, such, for example, as a placenta. It follows, therefore, that he looks upon puerperal septicemia—and, indeed, he expressly says so—as the result of an infection with a specific virus. This doctrine, then, should be kept prominently in view in the discussion, and some confusion in the debate might perhaps have been avoided if it had been found practicable to apply some other term than septicemia to the condition caused by the specific infection referred to; for, certainly, the word septicemia calls to mind at once the idea of a poisoning of the blood by the absorption of mere septic—i.e., putrid or pusrescent—material, and rather implies the absence of any special property that material beyond putridity pure and simple. It seems vain to hope that the discussion will not be marred by the various speakers confusing terms which, like septicemia, ichorhemia, pyemia, and the like, are often made use of with little if any discrimination as to their real meaning. It is well, therefore, that Dr. Thomas took pains to inform his hearers as to just what he meant by the term septicemia as used in connection with the subject of his paper.

Beyond the mere signification of terms, however, and over and above any confusion due to their varying interpretation, the part played by blood-poisoning in puerperal fever is scarcely viewed precisely alike by any two men. We do not gather from Dr. Thomas's paper that he regards it as practically the sole or even the only important element in the course of the disease, however prominent he may look upon it as an aetiological factor. Those who take part in the adjourned discussion will doubtless bear this distinction in mind, and it will be well for those who read the paper to do the same. Dr. Thomas is very careful to emphasize his sense of the great harm that would result from the indiscriminate use of intra-uterine injections in puerperal fever. Let the reader pay as much heed to this caution as to the potency of the method in proper cases, and the lesson to be learned from the paper and from the discussion will, we do not doubt, prove of the highest value.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending December 11, 1883:

<table>
<thead>
<tr>

The Typhoid Fever at Fort Jervis seems to have been traced conclusively to a dairy farm, as had been suspected. A report will soon be made to the State Board of Health by the gentlemen who have made the investigation in its behalf.

MORE SMALL-POX FROM THE SCYTHIA.—On Thursday of last week another patient with small-pox, one of the stewards of the vessel, was admitted to the Riverside Hospital from the steamship Scythia. It is reported that the ship was not subjected to any unusual detention at the quarantine station.

THE HEALTH OF DR. WILLARD PARKER.—Dr. Parker, as many of our readers are aware, has been the subject of a number of attacks of illness during the past year or more, which have given rise to solicitude. Last week he was seized with an acute sickness, and again there has been occasion for anxiety. At the time of our going to press, however, some improvement is reported, and we trust that his exceptionally vigorous constitution will lead to his speedy recovery.

THE HEALTH OF CONNECTICUT.—By the report of the secretary of the State Board of Health, for the month of October, we learn that diphtheria, which had decreased in prevalence for a time, has again become rife in Hartford, and that a thorough investigation is to be undertaken by the board.

MALARIA AT RHINEBECK.—The prevalence of malarial disease in the neighborhood of Rhinebeck has led to an investigation by the Committee on Sewerage and Drainage of the State Board of Health, with the result of establishing the fact that one or more railroads have practically shut in a body of water that should communicate freely with the Hudson, thus rendering it stagnant. The committee recommends that the railroads
be "requested" to build additional culverts through their embankments.

The Health of Michigan.—It appears by the report of the secretary of the State Board of Health, for the week ending December 1st, that, compared with the average for the month of November in the preceding six years, remittent fever, consumption, typho-malarial fever, intermittent fever, diptheria, bronchitis, and typhoid fever were less prevalent in November, 1883. A sanitary convention was held in Ionia on Thursday and Friday of this week.

The Sanitary Condition of Yale College.—A good deal has been said in the newspapers lately about the prevalence of typhoid and malarial fevers among the students. In an after-dinner speech, last week, President Porter is reported to have said that positively no case of sickness had been traced to insanitary local conditions, and he intimated that there was now no greater prevalence of the diseases in question in New Haven than was to be looked for in a town so situated at this season of the year.

The New York Academy of Medicine.—The following-named gentlemen have been nominated to fill offices, vacant or about to become vacant: Vice-President, Henry D. Noyes, R. F. Weir; Trustee, C. R. Agnew, S. S. Purple; Treasurer of the Board of Trustees, J. H. Hinton, D. B. St. John Roos, F. A. Castle; Committee on Admissions, Daniel Lewis, E. H. Jones; Committee on Education, W. Gill Wylie, John Shryady; Committee on Ethics, C. Dixon Varley, F. V. White; Committee on Library, A. Jacobi, H. D. Nicoll; Treasurer, E. H. Penlee, W. F. Cushman.

The Medical Society of the County of New York will hold its next meeting on Friday evening, December 21st, instead of Monday, the 24th.

A Marine Hospital for New York.—A memorial has been presented to the House of Representatives praying Congress to provide for the establishment of a permanent marine hospital in the neighborhood of New York. The petition is indorsed by the Chamber of Commerce, the Produce Exchange, the Maritime Association, the Board of Trade and Transportation, the Cotton Exchange, the Mining Exchange, the Stock Exchange, the National Petroleum Exchange, the Sailors' Snug Harbor, the American Seamen's Friend Society, and the Sandy Hook pilots.

A Polluted Water Supply.—The water supply of the city of Waterbury, Conn., drawn from Mad River, is reported to have become quite impure of late, owing, it is supposed, to the river having been tainted with refuse material from a number of factories that have been established on its banks.

The New Wing of St. Vincent's Hospital was visited by a number of invited members of the profession last Sunday, and the impression made on the visitors was in the highest degree creditable to the institution.

Alleged Grave Robbery in Baltimore.—The report reaches us that Dr. Randolph Winslow, the demonstrator of anatomy in the School of Medicine of the University of Maryland, was lately arrested, together with a colored man, under circumstances which tend to the suspicion that they were preparing to desecrate a grave in the Bayview Asylum Cemetery. They are said to have had a horse and wagon in waiting in the neighboring wood, and a bag containing a spade was found on the negro. After a hearing before a justice of the peace, they were admitted to bail pending action by the county authorities. We trust that Dr. Winslow will succeed in establishing his innocence.

Cremes reclaimed from a Dissecting-Room.—The bodies of two men were recently delivered to the friends of the deceased, on the requisition of the keeper of the Morgue, after having been partly dissected in the anatomical rooms of the Medical Department of the University of the City of New York, to which they had been delivered in accordance with the provisions of the Anatomy Law. The bodies had not been traced until after the lapse of the time they were required to be kept at the Morgue. Not only were they given up without objection, but every effort seems to have been made to repair their mutilation so far as possible.

The Orange County Farmers' Milk Company has very properly asked the State Board of Health to examine into the truth of the allegations lately made by a physician of Goshen as to the neglect of proper sanitary precautions by the milk-producers.

Color-Blindness in the Navy is probably to be made the subject of an investigation by order of Congress.

The Joint Congressional Committee on Epidemic Diseases consists of Messrs. Harris, Garland, Jonas, Hampton, Sewell, Bowers, and Fry.

The "Index Medicus."—The publisher of this most meritorious periodical has issued a circular in which a fresh appeal is made to its subscribers, and to those who ought to be on its list, to aid in saving it from the necessity of being discontinued for lack of support. The following questions are asked of each subscriber: "If the subscription price of the 'Index Medicus' is fixed at $10 per annum, are you willing to renew your subscription for 1884 at that rate? 2. Should not 500 subscribers renew at $10, will you be one of 417 subscribers who are willing to renew at $12?" The publisher also suggests that a more active support among medical societies would provide for a division that would entail but small expense on individuals. We cheerfully repeat all that we have said in the past in commendation of the "Index," and trust that the profession will not suffer it to die.

The "Christian Healer," having apparently been disgusted with his treatment in Brooklyn, has set himself up in New York. We commend him to the County Medical Society.

The "Pittsburgh Medical Journal."—With its December issue, completing the third volume, the "Pittsburgh Medical Journal" ends its existence, at least for a time. The career of the "Journal" has been creditable, and it is to be regretted that, for reasons which are given, the editors find themselves unable to continue its publication.

Obituary Notes.

Friend D. Lord, M.D., of Newton Lower Falls, Mass., died on Saturday, the 8th inst. He was a native of Maine, and was graduated from the Medical School of Bowdoin College in 1847. He removed from Sterling, Me., in 1867, to Newton Lower Falls, where he had been much esteemed as a citizen and a physician, and was noted for his kindly interest in the poor, having given his professional services freely to those who needed but could not pay for them. He was a member of the Massachusetts Medical Society, and of the Middlesex South District Medical Society.

J. Leight Dohmen, M.D., of Baltimore, died on Sunday, the 9th inst., at the age of twenty-five. He was graduated from the University of Maryland School of Medicine in 1880, and was a member of the Medical and Chirurgical Society, the Microscopic Society, and attending physician to the Presby-
rion Eye and Ear Charity Hospital. At the time of his death he occupied the clinical chair of Diseases of the Eye and Ear in the Baltimore Medical College.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

A stated meeting was held December 6, 1883, for the reading of papers on the prevention and treatment of puerperal fever. [See page 649.]

Dr. W. M. Polk was requested to open the discussion, and said that he believed he uttered the thought of every member of the Academy in saying that we were deeply indebted to Dr. Thomas for his able and eloquent presentation of this most important subject. The author had discussed the entire question so fully that there seemed but little left to be said, especially with regard to treatment. With regard to the pathology, however, he thought it would perhaps have been better, in view of the stress which Dr. Thomas laid upon antiseptic treatment, which, of course, most of us would accept, if he had planted himself more squarely upon the pathological view which regarded puerperal fever as identical with septicemia and pyemia. So long as there was any doubt with reference to this point it seemed to him that some doubt would be felt by many in regard to the propriety of many of the measures advocated in the paper. So far as he himself was concerned, he considered the disease as identical with that of surgical septicemia and pyemia. He did not mean to say that the future might not bring forward facts which would tend to change this view, but, as the question now stood, he thought that it was the one which should be accepted. If we would look at the clinical history of puerperal septicemia we should find that it was identical with that of septicemia and pyemia as seen in surgical cases; the lesions were the same. Such variations as were manifest in the symptoms or pathological lesions were to be accounted for by the peculiar condition of the tissue involved. It was only in the domain of pathology that those who opposed this view found their last refuge. They maintained that there must be some peculiar poison which could excite the disease in so many individual cases. But, if it was taken into consideration that a woman recently delivered had within her pelvis a sluggish stream of effete material, which, owing to the dilated condition of the blood-vessels and lymphatics, making them unable to respond properly to blood pressure, found its way into the general circulation, and if it was also remembered that the blood corpuscles in these patients were deficient, and, that consequently, their ability to oxidize tissue, and especially poisonous material, was diminished, we should recognize a condition which was quite sufficient to account for the peculiar susceptibility of the puerperal woman to this poison—a susceptibility which certainly was greater than in almost any other condition.

As to the matter of treatment, accepting, as he did, the view that the affection was identical with septicemia and pyemia, the principles of Listerism as laid down by Mr. Lister and his followers, and as had been so ably advocated by Dr. Thomas to-night, it seemed to him, entirely covered the ground. So far as precautionary measures were concerned, he thought there was absolutely nothing to be added to those mentioned by Dr. Thomas. He would merely suggest that, in this city, where defective drainage was known to exist, the question of the purity of the air was one which should be specially inquired into. It was well known that cases of diphtheria or scarlet fever were modified by the surrounding atmosphere, and nothing was more certain than that, if a patient in the puerperal state were confined to an unwholesome atmosphere, she must suffer in consequence. So far as measures of actual treatment were concerned, he had but one simple suggestion to make, namely, that in his experience it had often occurred to him to use intra-uterine injections, when in reality the sole lesion that was leading to the death of his patient existed in the cervix. As a general thing, the stream of water, as it flowed from the interior of the uterus, was not of sufficient weight to separate the closely applied cervical walls, which were often in a sloughing condition. It had been his rule, therefore, to make a thorough inspection of the genital passages, by means of Sims's speculum, as far up as the external os, and then to draw down the cervix by means of a tenaculum, and separate its surfaces in order to learn the true state of things there; and, if he found any lesion, he applied directly to the spot a strong solution of carbolic acid or some other strong disinfectant. In fact, in many cases, this had been about the only treatment which he had found necessary. With regard to the interior of the uterus, if the condition of the vagina and cervix did not seem to be the cause of the disturbance present, the practice had been advocated of introducing borated cotton, twisted upon an ordinary applicator, and dipped into a two-per-cent. solution of carbolic acid, up into the interior of the uterus, and thoroughly wiping out the cavity. Dr. Polk had even gone further in cases in which he had reason to believe that there was decomposing material in the uterus, and had introduced a particular kind of curette, known as Skene's curette, a blunt instrument, that could be carried up into the uterus, and, if handled gently, without doing any harm. With this he had been in the habit of removing any portions of membrane that might be present. In conclusion, he would merely say that, if we were to adopt the measures which had been so appropriately and so ably advocated by the author of the paper, we must go a little further than he had seemed willing to go, and plant ourselves squarely upon the ground that we had to do with a condition of things that in no respect differed from surgical pyemia and septicemia.

Dr. J. B. Hunter said that Dr. Thomas, it seemed, had left very little to be said upon the subject under consideration, but he should be very glad if he were able to say a part of that little. There were two or three points in the paper with regard to which he would differ from Dr. Thomas. He would speak only on practical points. In the first place, referring to puerperal septicemia, as the author had called the condition, and not to puerperal septicemia, he had firm convictions on the subject of washing out the uterus based on personal experience. He could testify as to the difficulties of doing it, and he did not think that it should ever be intrusted to a nurse. In its performance, it was very important that the patient be disturbed as little as possible, and he thought that the method described by Dr. Thomas would give the patient unnecessary disturbance. If a large bed-pan were used, the uterus could be washed out while the patient lay upon her back, without disturbing her position in bed at all. With regard to instruments for this purpose, he did not like the one passed around, namely, Chamberlain's unmodified. He had had one made for this special purpose, being of about half the caliber and half the length of Chamberlain's, and the apertures were grouped near the end of the tube. Chamberlain's instrument was too large, and the water escaped through the apertures into the vagina before it reached the distal end. He had found, after making two or three injections at intervals of three hours, that the uterus was apt to contract, so that it was difficult to introduce the tube. In that case an instrument of smaller size could be employed, such as Nott's double catheter. He had sometimes found it necessary to put the
patient on the side, and dilate the canal somewhat, so that the tube could be passed again. A point of special importance in carrying out the treatment was to have the injections given regularly, and with perfect gentleness, without disturbance to the patient. It was often difficult to get appropriate co-operation between the patient, the nurses, and the family, as they were apt to think something improper or dangerous was being done. As to the effects of the injections, he had found a very common fear of its producing shock or other disturbance, but such fears had never been realized. He had seen but a single case in which anything approaching a chill had been produced by it, and in that case it was due to the fact that the water employed was a little too cool; it was scarcely as warm as the temperature of the body. He was in the habit of employing a carbolized solution at 110° F. He usually gave the injections once in three hours, but their frequency should be regulated by the temperature, and for this reason a physician should be present with the patient all the time. He had found it necessary in some cases to repeat them every two hours. He had often witnessed the fluid coming away clear, and it might be regarded by those present as an indication that a mistake had been made, and that the affection was not due to the condition of the interior of the uterus; but, if the injections were continued, it would be found that they were accompanied after some hours by a fall in temperature. In one case, in which the patient was considered by her attending physicians as moribund, delivery had taken place seven weeks before. She had had a temperature, for six days before he saw her, of from 103½ to 105°. The uterus was washed out, although against the judgment of some of the physicians present, and, this being repeated every two hours, at the end of twenty-four hours the temperature was brought nearly down to normal. The injections were suspended, and the temperature rose again. The case was not one of peritonitis, but of septic poisoning. The injections were continued for three days longer, the temperature being thereby controlled, and at the end of that time the patient was out of danger.

He did not think that the coil referred to by the author should be used in simple puerperal septicemia. In peritonitis he had the strongest possible confidence in it. But in puerperal septicemia, if there was no great tenderness over the abdomen, and the patient evidently was not suffering simply from high temperature, he thought the use of cold water was very misleading. The temperature in any case could be lowered by the coil, but it might be done in septicemia and lead one to overlook the fact that all the while there was being absorbed more and more of the septic material. In one case in which he had employed it, after removing it he was able to bring down the temperature and keep it down by the use of intra-uterine injections. When the coil was used, he preferred metal to rubber; it weighed less, was far more manageable, and could better be kept clean. Wrapping the rubber coil with wooden material was especially objectionable.

Dr. E. L. Partridge said that he would speak only with reference to certain practical points which had been brought out. He certainly did not think, with regard to the pathology, that there could be any essential difference to the minds of those who had had experience in the management of obstetrical cases with septic poisoning. With regard to prophylaxis, with the same emphasis that Dr. Polk had spoken of pure air would he speak of extreme cleanliness, especially on the part of the medical attendant. He would just as soon place a patient about to be confined under the care of certain gentlemen who were daily making autopsies at hospitals as under the care of many physicians who were very careless with regard to personal cleanliness. Thorough cleansing of the nails with the brush and general cleanliness on the part of attendants were probably the most important points in the prophylaxis of puerperal septicaemia. As to the treatment of septic poisoning after it had been established, he would use the intra-uterine injections with the same frequency that had been recommended by Dr. Thomas and the other gentlemen. With regard to the agent to be employed, he would simply say that about a year ago the late Dr. Beverley Livingston introduced a supplement to the intra-uterine douche into the Nursery and Child's Hospital, which he believed to be of great value. After thoroughly cleansing the uterine cavity by means of the douche, he took a mixture of iodiform and glycerine, one to ten, and injected it into the uterine cavity. The iodiform was thus left in contact with the uterine walls longer than any antiseptic material otherwise introduced, and it did away with the necessity of repeating the douche so frequently. He approved of the bichloride solution, 1 part to 2,000, and, if it were not better than, it was certainly as efficacious as a solution of carbolic acid. He believed in the use of the coil for the reduction of temperature in puerperal septicemia, even when there was no peritonitis. In these cases the temperature should be kept down, and this was one of the most efficient means for doing so. We should not always look for immediate and marked results, but should be satisfied if the case ran along with only a moderately high temperature. There was no other part of the body where the coil would be so efficient in controlling the temperature as over the abdomen. Perhaps the reduction of the temperature was due in part to its influence upon the solar plexus. Further, he favored the rubber coil, and for the same reason that Dr. Hunter had given when he expressed his preference for the metal coil: that it was easier to keep clean, especially if foreign bodies entered the tube from the melting ice. The objections made to the use of the coil had been more on the part of the patient's friends and the nurses than from the patient herself. When first applied, she complained of about as much discomfort as patients did on receiving their first rectal injection, and afterward often expressed herself much more comfortable with than without it.

The President said that, as the hour was growing late, and as a number of gentlemen were present who had not yet had an opportunity to discuss the paper, he would suggest that further discussion of the subject be postponed until a future meeting of the Academy. Twenty-five years ago a long discussion upon this topic took place in the halls of the Academy, and eight years ago the Obstetrical Society of London appointed a special meeting for the same purpose, at which he was invited to be present and to give expression to his views. At that time the views which he advocated he believed were not shared by a single gentleman present, but a large number of prominent persons who then opposed them were to-day in full accord with him, and had told him so. The author of the paper had not considered it worth while to make any allusion to those views, confining himself to an expression of his own, as he had a perfect right to do, but it seemed to him that, on so important a subject, it would be well, so far as possible, to have all views brought out, and that there should be an opportunity for a full expression of opinion. There were points in the paper with regard to which he held views quite different from the author's, as, for instance, with regard to the pathology. He would accept in every particular the author's description of septicemia in the puerperal state, but as to the sum total of the conditions present he would differ from him. As there were many other gentlemen also present who had not had an opportunity to discuss the paper, on account of the lateness of the hour, he would suggest that the first meeting of the Academy in February be set aside for this purpose, and, if it would not be considered improper, he would propose to open the discussion himself on that occasion.

On motion, the suggestion of the President was adopted.
COLLEGE OF PHYSICIANS OF PHILADELPHIA.
Meeting of November 7, 1883.

Enteric Paraplegia.—Dr. Roberts Bartelow read the following paper:

By the term enteric paraplegia I intend to express the conception of a spinal paralysis, produced by an intestinal disorder. It is a truly reflex paralysis. The fact of the existence of such a malady is denied by many, and, indeed, most of the reported examples will not bear careful inspection, for it will be found, as I shall show, that they are really cases of ascending neuritis. Eliminating such from the examples of true reflex paraplegia to be found recorded, I intend to place the latter in a special group composed of cases presenting the symptoms of an enteric disease, during the course of which a motor and sensory paraplegia manifests itself, and pursues a course obviously dependent on the original lesions. The cases I have lately seen occurred in men over sixty years of age, and each one presented a morbid complexus so distinctive and uniform as to entitle it to be regarded a substantive affection—a pathological entity. Although such cases have been described as examples of reflex paralysis, they have not been adequately differentiated from others similarly classified, but of different nature. Before attempting the task of analysis and differentiation, I must give a brief outline of three cases, the most recent which have come under my observation.

Case I.—Mr. R., aged sixty-four, merchant and banker, of very vigorous and robust frame, rather spare and bony in outline, but capable of great endurance, called on me a year ago, among other physicians of this city, for relief to an obstinate bowel affection. His story was this: For a year or more previously he had suffered with intestinal indigestion, colic pains, flatulence, and considerable depression of spirits. Soon after these symptoms were experienced he began to have pain in the back, with more or less band-like constriction of the abdomen, a feeling of numbness in the feet and legs, a strong sense of fatigue in the inferior extremities, followed by weakness and awkwardness of movements in walking, obstinate constipation, and dullness in the emission of urine. For the relief of these alarming symptoms he consulted an eminent practitioner of this city, who diagnosed myelitis and advised erect posture, which probably contained ergot. Without using any of the local applications, Mr. R. took the pills, which had a favorable effect in relieving the flatulence and constipation, but presently dysenteric attacks supervened, and then a remarkable change ensued in the spinal symptoms. Up to this period the paraplegia had steadily increased, and walking had become exceedingly difficult, but the change in the condition of the intestine effected a revolution in the state of the spinal functions, and in the course of a few weeks all the paralytic symptoms had disappeared. Still troubled with intestinal indigestion, Mr. R. finally consulted me, among others, when I learned the details of the case just given. Very recently I have heard that Mr. R. continues free from the spinal symptoms, and has, in the main, got rid of his intestinal disorder.

Case II.—Mr. P., a tall, thin, but hardy Quaker farmer, aged seventy-two, I saw the patient at his home near Delta, York County, this State, in consultation with Dr. Hickman, a very intelligent practitioner living there. I learned that the patient, some ten years before, had experienced a similar attack, but had recovered rather suddenly under the influence of some remedies which were then prescribed. For some years he remained comparatively free from disorders of digestion. The present attack came on during the past winter; at first there appeared a very considerable disturbance of digestion— acidity, pyrosis, flatulence, and colic pains. The distress was increased by taking food, and apparently attained its maximum when the alimentary materials entered the intestines. In fact, the symptoms of intestinal indigestion were the most pronounced throughout, and to these were added obstinate constipation, the stool consisting of balls united by masses of mucus or coated with the same. Very soon after the gastro-intestinal catarrh was established, Mr. P. began to experience numbness of the feet and legs, and an increasing difficulty of locomotion. At the time of my visit with Dr. Hickman the patient was nearly entirely disabled. The history of very severe and continuous digestive troubles was repeated. I will, therefore, to occupy as little time as possible, pass on to the objective examination of the paraplegia. He could not stand without assistance; there was an extreme degree of stasis; the muscles were so weak that his utmost efforts could not at all hinder slight movement of extension when the legs were flexed on the thigh; the tactile sense was so lowered that the points of theesthesiometer could not be felt at all; the muscles responded feebly to an induction current; the emission of urine was very slow and there was much dribbling afterward, and the bowels were extremely sluggish. There was a feeble knee-jerk. With attention directed entirely to the digestive trouble, beginning with an exclusive milk diet, in two weeks a marked improvement was manifest in all the symptoms, the paraplegia disappearing. In a letter recently received from Dr. Hickman, I learn that, after a period of very great improvement, Mr. P. began to decline in strength, owing to failure of the functions concerned in nutrition.

Case III.—Mr. McK., of Clearfield County, about sixty years of age, has had for many years frequent attacks of sick headache. Within the past year pronounced symptoms of intestinal indigestion, pain of a colicky character, flatulence, and irregular action of the bowels, etc., have come on; but the symptom which has caused the greatest apprehension, and on account of which, more especially, he has called on me, is an increasing numbness, with some diminution of power, of the inferior extremities. The tactile, pain and temperature senses are not abolished, only slightly impaired, and the tendon reflex is unaffected. A feeling of fatigue, of weight and heaviness is felt in the legs, but locomotion is not as yet much affected. I await further developments in the symptoms referable to the nervous system, but meanwhile treatment is directed to the gastro-intestinal disorder.

Cases similar to those which I have thus briefly outlined have been recorded by various observers. An admirable example, and one of the first of its kind, was narrated by that eminent clinician, Graves, of Dublin (“Clinical Medicine,” edition by Noligan, vol. i, p. 558). In this ease extreme gastric disturbance, with less important intestinal, came on in distinct paroxysms, varying in duration from several days to two or three weeks, and accompanied by complete motor paraplegia. For a time, entire recovery took place, the paralysis disappearing with the cessation of the other symptoms. Finally the attacks grew so frequent as to be almost continuous, and death ensued from exhaustion. The minutest examination failed to disclose a lesion in any organ of the body. With the advance in our means of investigating morbid states, such cases of presumed functional disease of the nervous system are becoming more and more rare. That there is a condition of reflex paraplegia, due to anemia of the cord, is a postulate I expect to maintain. That there is, however, a so-called reflex paraplegia connected with diseases of the gastro intestinal and genito-urinary tracts, which is not truly reflex, is another postulate that I believe to be susceptible of demonstration.

There was a period, in England more especially, when the notion of reflex paraplegia secondary to intestinal, renal, and genital disease was widely entertained. The cases first reported by Stanley (“Medico-Chirurgical Transactions,” vol. viii, p. 260), Brodie (“Lectures on Urinary Organs,” p. 115), Stokes (“Practice of Medicine,” “Treatment of Nervous Diseases”), Graves, and others, were supplemented by the striking narratives of Gull (“Guy’s Hospital Reports,” various papers). Then Brown-Séquard (“Lectures on Paralysis,” etc., 1861) gave a scientific explanation of the mechanism, referring the paralysis to vaso-motor action. It must be admitted, nevertheless, that the doctrine of a reflex paralysis has not maintained the position it once had. In no modern work is the subject
treated with the extent and gravity befitting an important disease.

The two postulates I propose to sustain are: 1. That there is a reflex paraplegia due to a functional disturbance of the intestine—enteric paraplegia. 2. That there is a paraplegia having its initial seat in the end organs of the nerves distributed to the mucous membrane, hence ascending to the cord by a progressive neuritis. As respects the first postulate, the cases I have narrated, and many others on record, demonstrate a causal connection between the enteric disorder and the spinal. That the paraplegia is functional is proved by its prompt cessation, when the cause is removed. One of the means of determining whether a given paraplegia is due to a myelitis or to mere anemia—that is, functional—is the subcutaneous injection of strychnine. At a late meeting of the American Neurological Association, Dr. Jewell, of Chicago, recounted his experiences with considerable doses of strychnine, in cases of paraplegia, which improved so remarkably that they must have belonged to the merely functional group. It is in a high degree probable that cases of merely reflex paraplegia—of enteric paraplegia—especially as they occur in aged subjects, are relatively frequent, and happen from a degree of intestinal disturbance that seems a mere accident of the morbid complex.

What is the mechanism? We are helped in our consideration of this question by physiological data. Kussmaul and Tenner (quoted by Erb) have shown that sufficient loss of blood will cause paraplegia. Tying the abdominal aorta, and its obstruction by disease—of which Gulf ("Guy's Hospital Reports," 1858, p. 331) has given a striking example—embolic blocking of the spinal vessels, as Panum (Virehov's "Archiv," Band xxv) has experimentally demonstrated, and large uterine hemorrhage, as Mornard-Martin ("Union med.," 1892) has shown, have alike stopped the spinal cord functioning. In other words, an insufficient blood-supply—an anemia—is a cause of paraplegia. Brown-Séquard in his lectures, published in 1861, maintained the thesis that a strong contraction of the vessels of the cord induced by reflex stimulation is the essential condition in reflex paraplegia. We should not lose sight in this connection of the degree of stimulation necessary. A moderate degree of intestinal irritation suffices, for the law of reflex contraction of the vaso-motor fibers may be formulated thus: irritation of the end organs of the sensory nerves, not too violent and long continued, stimulates the vaso-motor center in the medulla, and causes a general contraction of the arterioles; but excessive and protracted irritation depresses the vaso-motor center and relaxes the vessels. It seems probable that an ordinary intestinal indigestion, and the stretching of the nerve-fibers produced by retained gas, is a degree of irritation sufficient to produce the supposed effect. To the further elucidation of the mechanism of enteric paraplegia, it is necessary to recall the fact that the blood-pressure in the vessels of the intra-abdominal organs rises and falls within considerable limits in quite an independent manner, controlled doubtless by the same ganglia that regulate the caliber of the intra-spinal blood-vessels.

The circulation within the spinal canal is peculiar, in that the veins bear such a disproportionate volume to the arteries, and that the whole vascular supply is in a certain sense a diverticulum. Atheroma of the vessels will contribute to the result of reflex irritation, and hence it is that paraplegia has resulted from endarteritis of the spinal vessels.

The second postulate is that the paraplegia which succeeds to certain cases of enteric, renal, or genital disease is due to an ascending neuritis. Chronic dysentery, pyelitis, and vesical catarrh are affections during the course of which the spinal cord has become diseased. Lesions of continuity involving the terminal nerves in structural changes are necessary to the production of this effect. The part which ascending neuritis may play in causing anatomical alterations of the spinal cord is exhaustively shown by Friedrich in his monumental work on progressive muscular atrophy ("Ueber progressive Muskelatrophie, über wahre und falsche Muskellhypertrophie," Berlin, 1873). Whether we accept his conclusions or deny them, we can not withhold the full measure of admiration for his labors. Starting with the theory of an intra-muscular neuritis, Friedrich holds that, by an extension of this affection upward, the cord is ultimately reached, and the changes belonging to progressive muscular atrophy are wrought. The intra-muscular neuritis admitted, the rest may easily follow. Under the term "chronic ascending neuritis" Dumenil has described the changes in injured nerves which, caused by trauma, proceed from the point of injury up to and involve the cord. Vulpian has especially demonstrated the modifications produced in the spinal cord by the section of a principal nerve in a member, usually the sciatic ("Archives de physiologie normale et pathologique," No. 3, 1868, p. 443). The nerves of a limb amputated, as Dickinson has especially shown, undergo degenerative atrophy, and that part of the spinal cord in anatomical connection therewith also atrophies. Many other observations might be quoted, but these will suffice to show how changes in the cord follow injuries to peripheral nerves.

In paraplegia secondary to ulceration of the mucous membrane we can readily, I think, conceive of a lesion of the peripheral nerves and an ascending neuritis to which the succeeding changes are due. It follows that such cases require a very different prognosis from those of simple reflex paralysis. The course and termination of the latter are affected by the causal lesions, while the former pursue a steadily unfavorable direction from the beginning of the spinal symptoms. The differentiation of reflex from secondary paraplegia is made by attention to the following points:

Reflex paraplegia is sudden in its onset, or, at least, develops quickly; secondary paraplegia is gradual in its evolution; the former is soon complete in all points of its symptomatology; the latter attacks one spinal function at a time. Reflex paraplegia follows the fortunes of the producing malady; secondary paraplegia pursues an independent course; and, when the alterations begin in the spinal elements, they proceed in their own way, just as after amputation of a limb the changes in the cord go on in the associated nerve-fibers, or, as in Landry's ascending paralysis, the lesions proceed by contiguity of tissue. Reflex paraplegia, on and by itself, never proves fatal, nor does it inflict permanent damage; secondary paraplegia may be the cause of death, and, if not fatal, effects lasting mischief.

To this view of reflex paraplegia it may be objected that extreme variations in the vascular supply must ultimately lead to structural changes. This is certainly possible, but the spinal, like the cerebral circulation, is arranged to permit considerable variations in the amount of blood.

It remains to explain, if an explanation be possible, why intestinal or renal lesions may in one case produce a merely reflex disturbance, and in another set up an ascending neuritis. There are, probably, two reasons: 1. The depth and extent of the peripheral lesions; 2. An inherent susceptibility to degenerative changes in the nervous elements. The first to me has profound significance, and I have already alluded to it. A degree of peripheral irritation not too great will merely stimulate the vaso-motor centers, and cause anemia of the cord by tonic contraction of its vessels, but, when the lesions of the mucous membrane are of a destructive kind, depression of the trophic centers, as well as of the vaso-motor, ensues. That there is a neuropathic type of constitution, in which the nerve-tissues are peculiarly prone to take on morbid changes, is an indis-
putable fact. When the two influences coincide, the result is not doubtful.

I must, then, conclude that there is a malady which may properly be entitled *enterie paraplegia*.

NEW YORK PATHOLOGICAL SOCIETY.

A stated meeting was held November 28, 1885, Dr. G. F. Shepard, President, in the chair.

Dr. J. W. Howe presented a specimen, and read the history of a case, of *Popliteal Aneurism*, for a candidate for membership.

HYDROCEPHALUS.—Dr. H. N. Heineman presented the hydrocephalic brain of a child who died at about the age of two years. It was admitted into Mount Sinai Hospital with the history that when about two months old it fell from a chair, struck upon the head, and had not been well since. It afterward had had an eruption upon the body, and some febrile movement. The measurements of the head at about one year of age were twenty-three centimetres from the forehead to the occiput, and about fourteen centimetres from one ear to the other, posteriorly. There was some increase in size during the last six weeks of life. Before death the temperature rose somewhat, and finally to 104° F.; there was some vomiting; no convulsive seizure. The patient had not been able to walk, but lay in bed, the head resting upon a pillow. At death, the body weighed less than twelve pounds. The chief interest of the case was the great thinning of brain tissue. There was a little more than a quart of fluid in the lateral ventricles; the convolutions of the hemispheres were almost completely unfolded. There was no distension of the central canal of the spinal cord. The immediate cause of death was probably broncho-pneumonia.

SARCOMA OF THE STERNUM.—Dr. C. Heitzmann presented a specimen, and said that the patient, a physician, came to him in April, 1882, to have the blood examined, believing that he was suffering from leucocytoma. He had had malarial fever for years, and said the spleen was enlarged. Dr. Heitzmann found a decrease rather than an increase of the colorless blood-corporcles, and the red corporcles presented a peculiarly dark carmine color. There seemed to be some impediment in the circulation, and a change of climate was advised. A small tumor, evidently connected with the peristeam, existed over the sternum, which was afterward aspirated, and some of the bloody fluid sent to him for examination. The examination led only to the suspicion of sarcoma, but afterward the appearance of the colorless blood-corporcles was such as, in his opinion, indicated approaching death. Tapping of the tumor had been attended by considerable relief to the breathing, but on one occasion during the procedure the patient died. At the autopsy the body was much emaciated, and the tumor over the sternum, about the size of a large egg, was found connected with the peristeam, and to have communicated with the anterior medistinum through a hole which would admit the little finger. The cavity with which it communicated contained blood. The adjoining pleurs and the spaces of the lungs were transformed into fibrous connective tissue, believing not to be malignant in character. The primary tumor over the sternum, however, was found to be a sarcoma. The spleen was much enlarged and very firm. There was interstitial hepatitis. The bronchial glands were sarcomatous. Dr. Heitzmann said that he once made the diagnosis of sarcoma of the lungs in the case of a patient who spuit up a large number of globular elements, smaller than pus globules. His physicians had made the diagnosis of carcinoma. The autopsy showed sarcoma.

ACUTE PYEMIA FOLLOWING THE PASSAGE OF A SOUND.—Dr. G. L. Peabody presented the heart of a man who had died of acute pyemia following the introduction of a sound into the urethra. The sound had been passed for dilatation of a stricture in the bulbous portion, and apparently produced little injury. It was followed by chill and fever, and, in the course of a few days, resulted in death. At the autopsy there were well-marked signs of pericarditis, which had been recognized during life, and also acute ulcerating endocarditis, and commencing abscesses of the kidney. The blood-vessels in the neighborhood of the abscesses contained a greater number of micrococci than had been observed by Dr. Peabody in any other case.

ENORMOUS DILATATION OF THE URETER ATTENDING PARALYSIS DUE TO SPINA BIFIDA.—Dr. E. Van Santvoord presented a specimen from a boy who died at about the twelfth year of age in the Randall's Island Hospital. There had been spina bifida, attended by paraplegia and paralysis of the rectal and vesical sphincters. At six months of age the patient was operated upon, but in what way he had been unable to ascertain. The operation resulted in cure of the spina bifida. Following the cure there was restoration of power in the legs and in the sphincter ani, but difficulty with urination continued; the water had to be withdrawn by the catheter. When the patient entered the hospital it was supposed that, instead of retention of urine, contraction of the walls of the bladder would be found. When, however, the house physician passed the catheter, a quart of urine was withdrawn. Catherization was continued daily. The boy lost appetite, there were nausea and fever, the urine was turbid, contained pus and albumin, and, in the course of about three months, death took place from exhaustion. At the autopsy the bladder was found to be much thickened and sacculated, the left ureter was dilated to a size larger than the small intestine, the pelvis of the kidney was also dilated, and the organ contained numerous abscesses. The right ureter was less dilated, and the kidney contained abscesses.

EXTRAPATION OF THE METATARSAL BONES FOR BUNION.—Dr. L. H. Sayre presented some metatarsal bones which had been removed from either foot for bunion. The patient was a man about forty years of age, in whom the condition of the foot, which had existed for many years, gave rise to much difficulty in walking, and on two occasions had caused suppuration. The metatarsal bone was removed by means of a bone forceps through an incision on the dorsum of the foot. The incision was closed with black silk, the wounds united in less than two weeks, and the patient was now able to get about with comfort and had a movable joint.

ULCERATION OF THE STOMACH; DEATH FROM HEMORRHAGE; OBSCURE SYMPTOMS.—Dr. B. Robinson presented a specimen from a man about fifty-eight years of age, who entered the hospital in a state of partial mental alienation. He had been suffering for four or five months from difficulty in breathing and palpitation. There were edema of the lower extremities, some albumin in the urine, double pleuritic effusion, and cardiac enlargement and dilatation. The patient remained in the hospital, without particular change in the symptoms, until November 19th, when he was observed to be very pale, and to be breathing with difficulty. In this condition he soon died. The lungs presented the appearance of brown induration; there was considerable serous effusion into both pleural cavities; the heart was hypertrophied; the stomach contained a large amount of blood, and at the pyloric orifice was an ulcer which had been the cause of rupture of a blood-vessel, from which the fatal hemorrhage took place. It was remembered that a small amount of bloody discharge had taken place per rectum the evening previous. There had been no symptoms pointing to disease of the stomach during life; digestion had been good.

ABSCCESS OVER THE PARIETAL BONE; MENINGITIS; DEATH.—Dr. W. P. Norrlepf presented the skull and brain of a child, eight
months old, who, two weeks before death, presented an abscess over the right parietal bone. The symptoms were almost none, but, in looking back over the case, it appeared there had been some irritability, hyperesthesia, and some stiffness of the neck. There was no known cause for the abscess over the parietal bone. At the autopsy the convexity of the brain was thickly coated with pus. Careful examination was made, to determine whether there had been direct extension of inflammatory process from the abscess to the cerebral membranes, but with a negative result. Other organs normal, except a fatty liver.

An unusually Thin Skull.—Dr. J. A. Weyer presented pieces of a skull which was but little more than one sixteenth of an inch in thickness. The history was not known. The skull broke to pieces with a slight blow of the hammer. It might throw some light upon cases in which fracture of the skull was produced by slight blows, as by a thrust with an umbrella.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

(Co-continued from p. 640.)

Note on Paraldehyde as a Hypnotic.—Dr. J. C. Wilson read the following: Paraldehyde has, during the past year, been made the subject of occasional contributions from various sources to the journals. Its introduction as a drug is due to the Italians, and especially to Cervello, of Palermo, and Morselli, of Turin. It is, above 50° F., a colorless, limpid liquid, of a specific gravity of .998, boiling at above 225° F., and soluble in about eight parts of water at 52° F.

Chemically the aldehydes are bodies obtained by limited oxidation of alcohols, from each molecule of which two atoms of hydrogen are eliminated with the production of water, thus:

\[
\text{(Ethyllic Alcohol)} \quad \text{C}_2\text{H}_4\text{O} + \text{O} = \text{C}_2\text{H}_2\text{O} + \text{H}_2\text{O}
\]

By further oxidation acids are produced, and these correspond in composition with the alcohols whence they are derived, thus:

\[
\text{(Acetic Aldehyde)} \quad \text{C}_2\text{H}_4\text{O} + \text{O} = \text{C}_2\text{H}_2\text{O}_2
\]

In the presence of nascent hydrogen, however, aldehydes again take up their lost atoms of hydrogen and become alcohols.

Paraldehyde is formed by the action of certain acids, e. g., sulphuric, hydrochloric, sulphurous, etc., on acetaldehyde at the ordinary temperature; it is a crystalline body below 50° F., and is a polymer of acetic aldehyde; that is, its percentage composition is similar, but its molecule is a multiple of that substance, viz:

\[
\text{(Acetic Aldehyde)} \quad \text{C}_2\text{H}_4\text{O} \quad \text{(Paraldehyde)} \quad \text{C}_2\text{H}_2\text{O}_2
\]

I am indebted for information concerning this substance to the "Medical News" (July 28, and October 20, 1880), to Dr. C. L. Dana's communication in a recent number of the "Medical Record," and to Mr. Genois, of Messrs. Wyeth & Bro., from whom the specimens I have used were obtained.

The medicinal dose is from thirty minims to two fluidrachms. I have found a draught to be the average dose for an adult under ordinary circumstances. It is to most patients disagreeable, and must be administered with a considerable draught of water. The taste and odor are earthy and penetrating. Patients complain of this taste several hours after taking it, and may it be recognized by its odor in the breath. It is probably eliminated unchanged by way of the lungs.

Paraldehyde acts upon the cerebral hemispheres, inducing rather speedy drowsiness without preliminary excitement. "A lethal dose suspends the functions of the medulla and the respiratory center, and the action of the heart ceases after the respiration." One observer (Brown) noted a slight depressant effect upon the heart in a single instance. It is stated that neither nausea, depression, headache, constipation, nor any unpleasant after-effects have followed its administration. Several of my own patients complained of the disagreeable after-taste already alluded to, and one or two of nausea.

Dr. Dana gave a pap six months old a gramine by mouth. "The animal was at first much excited, running around and stumbling as if intoxicated. It showed no signs of pain or gastric disturbance. Its intelligence was not greatly disturbed; it came when called. Pulse ran up from 130 to 200; respiration was 20 to 24 and labored. In about twenty minutes it lay down and went to sleep. Pulse 140; respiration slower (15), and with labored inspiration. The animal was easily roused, walked around, then went to sleep again. Slept about two hours." Cervello has recently demonstrated a direct antagonism between paraldehyde and strychnine, the former diminishing the reflex excitability of the gray matter of the medulla oblongata, while strychnine increases it.

Paraldehyde has been prescribed as a hypnotic by the Italian physicians who have used it, in the various conditions calling for such a remedy, but they have found it especially serviceable in the sleeplessness of dementia paralytica, hysteria, and in other forms of disorder of the nervous system.

Dana employed it in doses not exceeding three grammes in a number of cases. In six cases it acted well as a hypnotic; in two it was helpful; in one it failed. Temporary relief of pain followed its administration in sciatica and supra-orbital neuralgia.

I have prescribed it in nine cases, with a view to its influence as a pure hypnotic. In one hysterical patient it acted well for a short time, but lost its effect, and was discontinued. In a patient who could not sleep, after having acquired the habit of watching an invalid at night, it procured prompt and refreshing sleep. In a lady, rendered sleepless by a sudden and appalling bereavement, it caused sleep, but was abandoned on account of the nausea which followed its administration. A gentleman who had sleeplessness and great mental depression, after a debauch, and who failed to sleep for several nights after reasonable doses of the bromides and chloral, took a draught of paraldehyde, and slept seven hours, waking refreshed and hungry. On the next day this patient, being disturbed after he had taken it, failed to sleep, but succeeded in sleeping on taking a second dose. The other cases were sleeplessness from ordinary causes, and were all more or less fully relieved. It appears to speedily require an increase of the dose.

If I may venture to express a personal view, it is that paraldehyde will prove a useful addition to our sleep-inducing drugs, but will supersede neither chloral, which it resembles in its effects, nor any others among them.

It is, like new products of the chemical laboratory, at present expensive. There is no reason why a demand for it should not cheapen it.

I thank Dr. O. Horwitz, resident physician in the Jefferson Hospital, for assistance in observing such of the cases as were treated in that institution.

NAVAL INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending December 8, 1883.—Medical Inspector D. Kindlehner, ordered to the United States steamer Hartford, Pacific Station, per steamer of the 10th inst. Medical Director A. L. Guion, detached from duty as member of Board of Inspection and Survey on the 15th inst., and placed on waiting orders.

Medical Director George Peck, ordered to report on the 15th inst. as member of the Board of Inspection and Survey.
REPORTS ON THE PROGRESS OF MEDICINE.

DERMATOLOGY AND SYPHILOGRAPHY.

BY EDWARD BENNET BRONSON, M.D.,
PROFESSOR OF DERMATOLOGY IN THE NEW YORK POLyclINIC.

PURPURA.—A discussion on this affection at a recent meeting of the British Medical Association was opened by an interesting paper by Stephen Mackenzie ("Brit. Med. Jour.", Sept. 1, 1883). The point which the author mainly sought to establish was that purpura was not properly an independent form of disease, but, in all cases, a symptom, and a symptom not of any one, but of various morbid states. An analogy with oedema, jaundice, and glycosuria was pointed out, all of which represent products of disease rather than the disease itself. The writer, in describing the different forms of purpura, followed, with slight modifications, the classification of Du Castel ("Des diverses espèces de purpura," Paris, 1883), separating (1) vascular, (2) toxic, (3) mechanical, and (4) neurotic forms. The first form is very comprehensive, including all forms of blood dyscrasia, such as specific diseases, and also diseases where the blood disorder is primary and all-important, as in profound anaemia and hæmœcysthæmia. It also included those conditions in which normal ingredients of the blood are defective (scurvy) or in excess, or where abnormal ingredients are superadded, such as bile, urinary constituents, etc. The term vascular would also apply to structural alterations or feebility of the blood-vessels. The second or toxic group included cases in which adventitious matters gain access to the system, such as mercury, phosphorus, mineral acids, salicylic acid, quinine, the iodides, and animal venom. The third or mechanical variety included all cases due to mechanical causes, such as heart disease, feeble circulation, varicose veins, paroxysms of coughing (as in whooping cough), thrombosis of venous trunks, and "probably" also including "simple purpura." In the last (neurotic) category would fall the cases in which the nervous system is primarily at fault, thus involving cases of "tabetic purpura," occurring "in connection with neuralgia and with diseases of the nervous centers," "purpura urticans," and neurotic eruptions (e. g., herpes) becoming haemorrhagic.

At the same meeting William Russell reported a case of purpura haemorrhagica in whichbacilli were found in haemorrhagic spots upon the heart, underneath the epicardium. They were sufficiently abundant to cause emboli. The capillaries were not merely blocked with the fungus, but were distented by them, and in some cases ruptured. The case suggests a new pathology of purpura haemorrhagica. Russell considers that the disease presents characters of a specific fever due to a specific poison.

A HYPERTROPHS FORM OF LICHEN PLANUS.—Lemoine describes in the June number of "Annales de dermatologie et de syphiligraphie," a form of lichen planus occurring in a child eleven and a half years of age which he regards as identical with the form described by Besnier and Fournier as "lichen coriace," and by Aubert as "lichen hypertrophique." A singular circumstance in connection with the disease was the occurrence at the same time of patches of alopecia areata upon the head, which appeared to bear such a relation to the lichen that in proportion as the latter healed the former increased, and vice versa. The lichenous patches occurred upon the legs below the knees in several different places, and were characterized by red papules that enlarged and coalesced to form considerably elevated patches that presented an uneven, grayish surface, traversed by the deepened furrows of the skin, producing a rough and manillated appearance. There was some scaling from the surface, and there was moderate itching. The patches were treated by erosion with the curette, followed by the Lister dressing. Afterward, the disease returning to some extent, frictions with green soap, baths, and applications of the soap in the form of continuous dressing, completed the cure. One of the papules, which was examined microscopically, showed much the same appearances as those found generally in lichen planus; but the epidermic layers were unusually developed, with marked thickening of the corneous layer.

It is noticeable in this case that no description is given of the characteristic papule of lichen planus with its peculiar livid, or dusky red color, suggesting the hue of a syphilitic ecchymose, and its flat or umbilicated, glistening summit. The description, however, answers very well to the appearances of the confluent, slightly raised patches that occur in lichen planus, except that the elevation seems to have been more considerable than usual. There is a class of cases occasionally observed here the relation of which to lichen planus is somewhat doubtful, and which bear some resemblance to the case of Lemoine. An irregularly shaped, sharply defined, infiltrated patch is raised considerably above the niveau. It is of a dusky color, resembling that of lichen planus, but its most characteristic feature is a peculiar: horny roughness of its surface, due to a partial separa-
tion of epidermic scales, suggesting the feeling of a nutmeg-grater. The disease sometimes itches—sometimes as much as lichen planus, in other cases not at all. It occurs upon the lower extremities most commonly, but also elsewhere.

HERPES PROGENITALIS IN WOMEN.—A very instructive paper on this affection was contributed by Unna to the August number of the "Journal of Cutaneous and Venereal Diseases." The main motive of the article was to controvert a proposition broached at a meeting of the American Dermatological Association a few years ago that herpes progenitalis in women was of rare occurrence. Unna shows very clearly, from abundant evidence, that in "puelle publice" it is an exceedingly common affection, becoming in them a veritable disease of vocation, while in other women there is reason to suppose that it occurs about as frequently as in the average of men. The writer takes occasion also to enter upon the subject of the etiology of this form of herpes as well as its pathology, especially touching its relation to zoster genitalis.

FILARIA SANGUINIS.—Prospero Sonsini communicated to the "Medical Times and Gazette" (Sept. 29, 1883) a report concerning this disease as observed in Egypt. He had observed twenty-two cases in human subjects. He concludes that "filariated individuals may live long without presenting disorders of importance, and even enjoy good health." They are liable, however, during the period of their infection, "to attacks of lymphorrhagia, and especially of lympharias, the lymphorrhagia in some cases assuming the form of lymphocede. The occurrence of one or the other complaint," he contends, "depends upon the seat of the adult worms." Haemorrhage, more particularly hematuria, "may also be the result of filarial parasitism, but exceptionally," due, probably, to the passage of mature filariae into the blood-vessels. But, as a rule, hematuria in Egypt is generally the result, even when occurring in filariated patients, of "the co-existence of bilharzial disease."

Sonsini also examined certain of the suctorial insects supposed to be capable of communicating filariae to man. He ascertained that in the Culex pipiens (mosquito), which is a common source of the disease, the developmental changes of the filaria did not take place during the colder months. They were first observed beginning in the month of March. In the cinex found inhabiting the beds of "filariated" persons, the embryos, which were found abundant at first, were afterward digested without undergoing transformation. The same was presumed to be true of the Pulex irritans (flea).

CICATRIZATION AND CORROSION OF THE SKIN.—In the
healing by second intention of a wound affecting the cutaneous surface, two distinct processes call for consideration, viz.: the growth of granulations appertaining to the connective tissue, and the formation of a corneous envelope which appertains to the epidermis. Not infrequently these two processes fail to act in harmony, and the result is either that, while the granulations are abundant, or even exuberant, the pellicle of epidermis fails to complete the healing, or, on the other hand, the granulation process is delayed while the epidermic layer tends either to close over a cavity, or, by folding in upon itself, to produce callous, indolent edges; or, finally, it may dip down to the bottom of the unfilled excavation, with the result of a depressed cicatrix.

Of these two processes Unna has recently made an interesting study ("Berlin. klin. Wochenschr.," Aug. 27, 1883). To distinguish them he has constructed from the Greek the names "dermatoplastia" and "keratoplastia," which translate the equivalent German words Überhautung and Überhornung. It is urged that such dissimilar and evidently independent processes cannot depend upon conditions that are identical. Conditions that promote one may delay the other. It has been Unna's special study to ascertain how they may be affected by different remedies. Often, when one process is in excess of the other, a change in the local remedy will at once overcome the difficulty. Thus, a wound which has been treated with carbolic-acid dressing may have assumed an apparently perfectly healthy condition, its granulations have brought it to a level with the niveau, but still it fails to "skin over." Then the carbolic acid is changed, perhaps, for a dressing of boric acid, and the healing is rapidly completed. The natural inference is that the delay was the fault of the treatment. The remedy that promoted the granulation failed to promote, or deterred the process of cornification. The writer proceeds to make a division between keratolytic remedies—i. e., those tending to destroy or dissolve the corneous layer—and remedies that are keratoplastic, or productive of corneous growth. Among the former he ranks many of the so-called antiseptic remedies, e. g., carbolic acid, salicylic acid, corrosive sublimate, the bromine and chlorine compounds, acetic acid, permanganate of potash, thymol, pyrogallic acid, peroxide of hydrogen. Though in the illusory form in which they are commonly used their keratolytic properties are not often seriously developed, it is chanted, nevertheless, that their influence is always more or less unfavorable to corneous growth. With regard to certain other remedies, such as iodine, boric acid, benzoic acid, acetate of aluminium, the balsams, salicylate of bismuth, and oxide of zinc, it is stated that, while devoid of properties injurious to the cuticle, they are not keratoplastic in their effects. On the other hand, there are certain remedies, though comparatively few in number, that seem to have the property of promoting the growth or regeneration of the stratum corneum. Such a remedy it is claimed is pyrogallic acid. Though used in certain affections, more particularly lupus, for its escharotic effect, it has (according to Unna) the extraordinary property, at the same time that it is destroying deeper tissue, of regenerating the cuticle.

In explanation of these opposite effects of different remedies, Unna has proposed a singular theory. As is well known, most of the antiseptics above named are strong oxidizing agents, and the same is true in greater or less degree of the other material under the keratolytic class. On the other hand, pyrogallic acid has very remarkable reducing or deoxidizing properties. Unna's theory is that substances that promote oxidation are stimulants to the granulating process, but are liable to hinder cornification, while remedies belonging to the class of reducing agents tend to promote the growth of cuticle, but often counteract the development of granulations. With regard to the first of these propositions, the case seems to be fairly made out, and it has been

the writer's chief endeavor to establish the second. Comparatively little is known concerning reducing agents adapted to external use. Most of them necessitate certain conditions—such as high temperature—that render them unavailable for the purpose desired. The writer, however, calls attention to several agents of this class which he claims are markedly keratoplastic in their effects. Pyrogallic acid has already been mentioned. Another is sulphanurtted hydrogen. It is produced when the sulphur alkalies are used, and also from sulphur itself. The former are usually objectionable because too irritating or caustic to the skin. On the other hand, a strong sulphur ointment is sufficiently mild, if not too long applied, and, as is evident from the odor produced, is attended with an abundant development of sulphurtted hydrogen. Unna cites several cases to illustrate the ability of sulphur ointment to cause rapid cornification of granulating surfaces which had previously shown little tendency to develop cuticle. Another property of this ointment, which was incidentally remarked, was that of reducing exuberant granulations, which it was found to do even better than the nitrate of silver. It was found especially useful for this purpose upon the granulating surfaces on the scalp that are often so rebellious. The writer also speaks of sugar (a strong reducing agent) in this connection, alluding to the fact that a common and very efficient remedy for fissures of the nipple is a powder consisting of sugar and gum-arabic. In impetigo contagiosa he states that it (sugar) has proved in his hands to be one of the best of remedies. Chrysarobin is ranked among these remedies, and evidence of its keratoplastic properties is deduced from the well-known fact of its tendency to cause comedones and acne. It also has some reputation in the treatment of eczema, though, as in the case of sulphur, its use can not be long persisted in. Tar also is mentioned in this connection, and especially linseed oil. The writer observes that often, when fats are not well borne by the inflamed skin, this oil heals. The virtues of carron oil are largely attributed to this ingredient. Reference might also be made to the success in the treatment of pemphigus foliaceus with linseed oil, reported by Sherwell, of Brooklyn.

Finally the writer calls attention to the importance of desiccation as a factor in cornification of the epidermis, pointing out the fact that many remedies, locally applied, promote this process through abstraction of water. In this way set many of the so-called "dusting powders," which, though commonly spoken of as "inert," according to Unna, directly aid the process of cornification, and similarly with certain astringents, such as tannin and alum, which have a sort of tanning effect upon the skin. Again, applications that compress the skin, such as the rubber bandage, tend to assist cornification by reducing the amount of watery fluid in the skin and subjacent blood-vessels. Unna, it may be observed, has maintained elsewhere that the development of the corneous layer is not due, as held by Ranvier and others, to impregnation of the epithelial cells with the peculiar substance termed by Ranvier "éclân," and by Waldeyer " Keratohyalin," which first makes its appearance in the stratum granulosum, but asserts that the process affects only the periphery or "mantel" of the cell, and that the most important factor in this change is a process of desiccation, or, as he terms it, "dehydration." Hence any application to the skin that assists this process tends also to promote cornification.

[It may be well, in connection with what Unna says of the cornifying properties of pyrogallic acid, to recall the fact that Vidal, Terrillon, Lermoyez, and Hitler, who have experimented with this drug in the treatment of chancræ, testify that its healing influence was confined to the destruction of the virulence of the sore, and that, so soon as the chancre had assumed the character of a "simple wound" level with the niveau ("dis que le..."))]
On the Treatment of Skin Diseases by Adhesive Applications.—In the treatment of certain forms of cutaneous disease it is often desirable to confine the action of the topical remedy as strictly as possible to the immediate seat or seats of disease, and to make the application adhere so closely to the skin as to be practically immovable. The want of such a "dressing" has been especially felt in the treatment of psoriasis by chrysarobin. One of the most objectionable features attending the use of the drug just named is the brownish or purplish staining of the skin and clothing. Singularity, this staining does not usually affect the psoriatic patch, but only the surrounding sound skin, together with the under-clothing. The reason of this, as explained by Pick, is that the discoloration is the effect of the reaction of the cutaneous secretions upon the drug, the exudation of the psoriatic patch being due to the fact that in the diseased portion of skin the secretory functions are in abeyance. An equally plausible explanation, as it appears to us, would be that the presence of the loose layer of epidermis, which is always present in greater or less quantity and which is exfoliated in the process of cure, prevents the pigment from affecting the layers beneath.

By means of a dressing which will confine the chrysarobin to the diseased patches, this general staining may be entirely prevented, together, also, with the general dermatitis which this substance is liable to cause. For this purpose the ointment commonly used is unsatisfactory, for the reason that it cannot be applied so as to be sufficiently immovable except by a complicated retaining dressing, which in certain situations, or when the disease is at all general, is impracticable. Plasters are for the most part inadmissible, for the reason that when they contain the drug in the desired proportion they possess insufficient adhesiveness. Dr. Fox, of this city, has suggested a paste of chrysarobin and water applied over the psoriatic patch, and then retained in place either by inclosing it in a film of collodion, or by covering it with a strip of gutta-percha tissue, the edges of which are made to adhere to the surrounding skin by moistening them with chloroform.

The method proposed by Pick, of Prague ("Monatshefte für praktische Dermatologie," No. 2, 1883), is as follows: A portion of pure, white gelatine is dissolved, over a water bath, in twice its quantity of distilled water, and, while cooling, the drug is stirred in to the desired proportion. Before the mass solidifies it is poured into a receptacle, where it hardens and forms a solid cake. When desired for use, a small portion is broken off and melted in a shallow dish placed in hot water. When liquid, it is painted over the affected part in a thin layer by means of a brush. As it hardens upon the surface it contracts, and is liable to crack, to prevent which a little glycerin is rubbed over it as it dries. It is not only in psoriasis that Pick has found this mode of application serviceable, but in various other diseases, notably dry forms of eczema and in pruritus, when, in place of the chrysarobin, salicylic acid is used in the proportion of from 5 to 10 per cent. Without this addition it is stated that the gelatine is liable to become affected with mold sufficiently to render it opaque. Generally the coating is perfectly transparent, enabling one to plainly see the diseased surface and watch the progress of the cure.

A similar method is proposed by Unna, of Hamburg ("Monatshefte f. prakt. Dermatol.," No. 2, 1883), which differs from Pick's chiefly in that Unna adds glycerin to the gelatin mixture at the start. He gives a comprehensive formulary, including a great variety of remedies. Three classes of mixtures are described, the first containing 5 per cent. of gelatine, the second 10 per cent., and the third 20 per cent., of the proportions of water, glycerin, and medicament varying. The first are described as "gelatine glycerinata mollis," and are applied in the same manner as described by Pick. The second, termed "gelatine glycerinata durra," are applied by pouring a few drops of hot water upon the hardened mass, by means of which sufficient of the gelatine will be softened, so that with a brush it may be painted over the affected surface. In certain of the formulas given, water is entirely dispensed with. This is true of the formula for chrysarobin, two of which are given as follows:

- Chrysarobin .................................. 5 per cent.
- Gelatine ..................................... 5 " "
- Glycerin ..................................... 90 " "

and,

- Chrysarobin .................................. 10 per cent.
- Gelatine ..................................... 5 " "
- Glycerin ..................................... 85 " "

In cases where the mixtures do not harden with sufficient rapidity after their application to the skin, owing to the proportions of the ingredients not being accurately adjusted, Unna sometimes covers the soft gelatin with a muslin bandage which adheres to it firmly, but may easily be removed by simply sponging the surface with water.

Auszitz ("Wiener med. Woehenschr.," 1883, Nos. 30 and 31) prefers to the gelatin preparations a solution of one part of gutta-percha in ten parts of chloroform (i.e., gutta-percha, U. S. P.), as an expeditious to the remedies used, more especially chrysarobin.

The advantages claimed for it over the gelatin mixture are that its application is much simpler; that the coating which it produces upon the skin, though thinner than the layer of gelatin usually applied, is more durable, being less liable to crack, and not subject to mold, as is the gelatine. The gutta-percha being elastic, a more uniform pressure is exerted by it, and it yields readily to the motions of any part to which it is applied, more particularly about the joints. It hardens more slowly than the gelatine, so that abundant time is given to make the applications as carefully and thoroughly as may be desired. It is stated that the gutta-percha solution is entirely unirritating to the surface, and, when combined with 10 per cent. of chrysarobin, the effect of the latter is completely controlled, the surrounding skin being wholly unaffected. This combination is recommended as an efficient remedy for herpes tonsurans, eczema marginatum, and prurigo, as well as for psoriasis.

The Treatment of Nævus.—In a paper read by Mr. William Martin Coates, at the annual meeting in August of the British Medical Association ("Brit. Med. Jour.," Aug. 18, 1883), the writer advocated for the treatment of superficial venous navi the "now almost forgotten method of Marshall Hall." It consisted in puncturing the skin at the distance of about a line from the growth with a cataract-needle, which was then passed horizontally into the substance of the nævus in different directions, by this means inducing a slight adhesive form of inflammation in the vascular tissue, which was followed by occlusion of the blood-vessels, and finally absorption of the growth. In the center of the nævus there first appeared a small white spot which gradually spread, and in time there was left only a smooth surface, appearing a little whiter than the surrounding skin. For the bright, scarlet-colored, or arterial navi the writer approved of a treatment similar to the above, in being merely stimulant and not destructive: A large needle, with a blunt, flattened point, was passed into the skin, previously anaesthetized, and made to tear its way through the dilated blood-vessels. In this case a number of white spots appeared scattered over the nævus, which gradually spread and coalesced, and after a time,
varying from six months to two years, the growth entirely dis-
appeared, leaving neither scar nor depression. The writer states
that when the nœus, whether venous or arterial, "exceeds a
thickness of one sixteenth part of an inch, the needle operation
is not applicable." In such cases he used injections of undiluted
iodine tincture. The needle of the syringe should be moved
about so as to inject every part of the nœus. The operation
was usually followed by some vesication. The white spots
then made their appearance, spreading in all directions. Heali-
ing was attended with slight depression of the surface.

At the same meeting Edmund Owen recommended for the
treatment of large nœvi the use of Paquelin's cauteria provided
with cutting blades. The latter, being heated to a dull red, are
plunged into the growth at several points, care being taken,
however, to keep well within the limits of the growth, since the
cauterization tends to extend a little beyond the blade. "A
few black sinuses, surrounded by a ring of skin which has been
redden by the scoring," remain after the operation. The
next day the part looks angry and swollen, and is painful. A
slight amount of sloughing takes place, and in a few days small,
clean ulcers are all that mark the dwindling mass. It is said
that the integument does not perish except where wounded.

The Action of Heat on the Virus of Chancre.—It is
maintained by Aubert ("Lyon méd.," Aug. 12, 1855) that the
virulence of the chancreous virus cannot be sustained when
subjected for a certain length of time to a temperature equal to
the normal temperature of the interior of the human body.
Matter taken from the surface of the sore was placed in vaccina-
tion tubes, and the effect of various degrees of heat carefully
noted. It was found that, after exposure for from sixteen to
eighteen hours to a temperature varying from 37° to 38° C.—
i.e., the normal temperature of the body—the pus globules be-
duced disintegrated and the virulent properties of the matter
totally disappeared, so that it was no longer inoculable. Ac-
cording to Aubert, these experiments afford an explanation of
the fact that the chancre poison does not penetrate the interior
of the body. It is only in situations so exposed to atmospheric
influences as to maintain a temperature considerably lower than
that of the interior of the body that the disease is able to take
root. When buboes occur, it is only the glands nearest the sur-
face that are affected. Chaneres of the neck of the womb, it is
stated, are of short duration, their appearance often changing
completely in twenty-four hours. Chaneres of the anus are
confined to the more exterior parts. With regard to buboes,
associated with chanere, we should naturally suppose that they
would always be chanereous or virulent in character, while in
fact the simple ones are about as common in this connection as
the virulent ones. The writer advances the hypothesis that
when they are simple in character their inception has been ac-
companied with fever, involving a temperature sufficiently high
and prolonged to annihilate the virulence of the virus conveyed
to the inguinal glands. Again, it is asserted that, if autoinocu-
al be practiced during an intercurrent febrile attack, it will
not succeed, though when the fever has passed it may be prac-
ticed successfully. It is suggested as a reason for the original
chancre not being similarly affected during fever, that (aside
from the fact already mentioned, that the region it affects is apt
to be more under the influence of the surrounding temperature
of the atmosphere than the rest of the body), the fact that the
virus would naturally be more easily destroyed when first in-
oculated than after it has had time to develop or establish itself.
The fact, also, is alluded to that the chancre has its virulence
obliterated by an attack of erysipelas or gangrene, involving its
site. On the other hand, in situations where the normal local
temperature is habitually low, the chaneres are most apt to be
large and severe in character. Deducing therapeutic indica-
tions from these considerations, the writer aims to imitate the
action of an attack of erysipelas affecting the region occupied
by the chancre. His observations taught him, however, that
simple heat, applied superficially, was not enough, but that
this should be supplemented by an elevation of temperature
more generally. To this end the patient is kept in a sitz bath,
or, better, the "half" bath, at a temperature of from 40° to 42°
C., for a period of several hours, the part affected by the chan-
cre, as well as a considerable portion of that region of the body,
being immersed in the warm water.

[The theory seems a pretty enough one, but we should be
more convinced of its practical value if accompanied with re-
ports of cases in which the treatment had succeeded. It should,
however, be borne in mind that for phagedena and gangrene
the continuous bath has long been recognized as one of the best
methods of management, but of what importance the tempera-
ture is in this connection is a question.—E. B. J.]

ANTIMONY IN SKIN DISEASES.—Considering the therapeutic
value of arsenic and phosphorus in cutaneous diseases, it has
occurred to Malcolm Morris ("Brit. Med. Jour.," Sept. 22) to test
the cutaneous substance, antimony, with a view to obtaining simi-
lar effects. It was used in doses varying, according to age, from
2 gr. to 3 gr. of a grain, or of the wine from 4 minims to 7/2
minims. In certain cutaneous affections it is stated that the results
were favorable. It was found very useful in the acute general
forms of eczema, and especially in that form known as eczema
rubrum. In chronic eczema it was less successful, though excava-
tions were relieved by it. Eczema impetiginosum was not bene-
fited by it till suppuration had been stopped by local meas-
ures.

In that form of erythema which is prone to relapses, the
antimony shortened the attacks and diminished the severity of
the symptoms. The remedy was also found useful in the mild
form of prurigo observed in England, as well as in some cases
of chronic urticaria. It also appeared to do good in those cases
of psoriasis in which arsenic is not well borne.

The administration of the drug was not attended by depres-
sion, diarrhoea, nausea, sweating, or other bad symptoms.

Miscellany.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving
in the Medical Department of the United States Army from December 1,
1883, to December 8, 1883.—Carter, W. F., Captain and Assistant Sur-
ger. Releived from duty at Washington Barracks, D. C., to take
effect at the expiration of his present leave of absence, and assigned
to duty at Little Rock Barracks, Ark. Par. 4, S. O. 224, Department
of the East, November 30, 1883. ——- Shufeldt, R. W., Captain and
Assistant Surgeon. Now on sick leave, relieved from duty at Jackson
Barracks, New Orleans, La. Par. 3, S. O. 224, Department of the East,
November 30, 1883. ——- Richard, Charles, First Lieutenant and
Assistant Surgeon. Assigned to duty at Jackson Barracks, New
Orleans, La. Par. 2, S. O. 224, Department of the East, November 30,
1883.

NAVAl INTELLIGENCE will be found on page 672.

SOCIETY MEETINGS FOR THE COMING WEEK.—Monday,
December 17th: Medico-Chirurgical Society of German Physicians. Tu-
esday, December 18th: New York Academy of Medicine (Section in Medicine);
New York Ophthalmic Society (private); Medical Society of the County
of Kings, N. Y.; Ogdensburg (N. Y.) Medical Association. Wed-
nesday, December 19th: Roman Medical Society (private); Medical Societies
of the Counties of Alleghany and Tompkins, N. Y.; New Jersey Acade-
y of Medicine (Newark). Thursday, December 20th: New York
Academy of Medicine. Saturday, December 22d: New York Medical
and Surgical Society (private).
Lectures and Addresses.

A LECTURE ON
ACUTE MENINGITIS,
DELIVERED IN THE MEDICAL DEPARTMENT OF SYRACUSE UNIVERSITY.

By WILLIAM T. PLANT, M.D.,
PROFESSOR OF DISEASES OF CHILDREN.

GENTLEMEN: Our topic for to-day is acute meningitis, one of the most formidable of all the diseases of early life. You will find it described in some of your books under the name of acute hydrocephalus; but, while you may find it useful to remember that fact, I hope you will not use that term. It served a good purpose once, but, now that we have a better knowledge of the disease, it should give place to the more appropriate name of meningitis.

We recognize two varieties—the tubercular and the simple. The former, being much the more frequent in children, merits our first attention. Acute tubercular meningitis is an inflammation preceded and caused by a deposit of tubercle within the skull. Examination made after death reveals the tubercles, not aggregated into masses, as they so often are in the lungs and other organs of the adult, but as minute, grayish bodies of pin-head size, sometimes larger and often smaller. They may be very numerous, or so few and sparse as to be found with difficulty. The severity and duration of the illness seem to bear little relation to their numbers.

You might fairly suppose from the name, meningitis, that all the membranes, dura mater, arachnoid, and pia mater, share alike in the tubercular deposit and the resulting inflammation; but it is not so. With few exceptions, if any, the granulations are in and upon the pia mater, and here the brunt of the inflammation expends itself. Nor do the tubercles spread themselves over the whole extent of this membrane. Search for them ever so carefully on the convexity of the hemispheres, and you will rarely find them; but lift the brain from its bed and examine its base, and you are at once rewarded. Here, between the optic commissure and the medullia oblongata, you may find the tubercular granulations in more or less profusion. Usually some may be found along the lower part of the sides of the hemispheres, as also in the processes of pia mater that dip down into the sulci between the convolutions. The membrane is often found thickened by an opaque, grayish infiltration that has been regarded as "confluent tubercle." 

Besides the tubercles and infiltration, you will find some of the concomitants and results of the inflammation, as hyperemia of the membrane and contiguous parts, flakes of lymph, and often serum and pus. Almost always there is adhesion, so that when the pin mater is peeled off it brings some of the brain substance with it. The inflammation may have invaded to some extent the brain itself, which will then present changes in color and in texture. It is common to find the fluid in the lateral ventricles somewhat augmented; occasionally the increase amounts to a quarter of a pint or more.

Quite generally, but not always, meningeal tubercule is associated with tubercle in other parts of the body, notably the peritonium and the lungs.

Whatever may contribute to produce a tubercular diathesis in a child may become a cause of this disease. Heredity is a chief cause. The offspring of consumptive and serofulous parents are specially liable to it. In pure and confined air, want of healthful exercise, and insufficient food and clothing, are powerful contributory causes. The recession of moist cutaneous eruptions is thought by some to be a cause. I have no doubt that there is some connection between the disappearance of such eruptions, especially if about the head, and this disorder. It is frequently secondary to other diseases, especially to measles and whooping-cough.

Symptoms.—Dr. Robert Whytt, of Edinburgh, whose admirable description of this disease was first published in 1768, two years after his death, divided it into stages, and his example has been generally followed by other writers. Not that there are distinct stages with sharply defined boundary lines; you are not to look for that, but rather for a gradual change and succession of symptoms answering to the progressive character of the malady.

With this understanding, we will follow the usual course and consider, first, a stage of invasion. From the standpoints of diagnosis and treatment, professional interest centers in this stage. He is a skilful diagnostican who, in the half-revealed and inconstant phenomena of the first days, can unerringly recognize the foe he has to meet. It is only at this time, too, that there is any hope at all of success from medical treatment.

You are called, then, to see a child between one and seven or eight years old, for this malady, like many others, is infrequent during the first year, and after the eighth or tenth the liability is greater to pulmonary phthisis than to meningitis. Perhaps the parents may have noticed that for some weeks, or even months, the child has been losing weight and color and spirit; that it has been easily fatigued and easily fretted; that it has been, for a child, too much inclined to silence and sadness; that it has been sleepy by day and restless by night. Frequently, however, these prodromous symptoms, if present at all, have not been sufficiently pronounced to attract notice.

The little patient does not seem to you to be very ill, but it has lost its usual animation and sprightliness, and it no longer finds pleasure in its toys. If old enough, it may complain of headache; if not so old, it may manifest its discomfort by carrying its hands to its head. It is apt to reel in walking, and it may be observed sometimes to come to a sudden pause and look about as if bewildered or surprised. When lying down it may cry out that it is falling, and beg to be taken up. These phenomena are doubtless due to vertigo. It inclines to drowsiness, and, when disturbed, is petulant and spiteful. When questioned, it replies in monosyllables; if, indeed, it replies at all. Its very silence is ominous of the coming storm. It prefers darkness, or rather twilight, to light, and instinctively closes its eyes and turns its face away when brought before a lamp or window. The eyes are unnaturally lustrous, and the
pupils, even thus early, are apt to be contracted. The hearing is often morbidly acute, and loud noises are distressing. At night the sleep is fitful and disturbed. Grinding of the teeth is frequent from spasm of the masseter muscles. Twitching of other muscles is common, and there may even be general spasms. Indeed, at any period of the disease there is a liability to general convulsions, and occasionally they occur at the onset. The temperature is somewhat raised, but is probably not above 101°. Very likely the pulse is a little accelerated, though it is sometimes slackened even thus early.

Constipation is an early symptom, and usually attends the whole course of the disease, excepting, it may be, the very last days. In a few instances there has been diarrhoea at the beginning, but of short duration, and followed by abating costiveness.

Another early and important symptom is vomiting. Often it is one of the first things noticed, and the child is thought to have a disordered stomach. It is repeated several times, in most cases during the first few days, and is sometimes so urgent as to interfere with nutrition. Raising the child from the recumbent posture frequently excites it. I would have you make note of the fact that vomiting is not present in every case, as has been asserted by some writers. I have known of several instances in which it was altogether absent. Barrier found it absent in about a fifth of the cases observed by him. It does not usually attend the latter part of the disease, and frequently disappears after two or three days.

Though the general temperature is somewhat raised, the face is commonly paler than natural, excepting now and then when a transient redness steals over it. Such are the ordinary phenomena of invasion. Not all of them are present in every case, and no one of them is specially characteristic. It is only through assiduous watching of the patient and weighing all the symptoms that you can arrive at an early diagnosis. The mistake is often made of pronouncing a commencing meningitis remittent or typhoid fever. Again and again I have committed this error, though resolving each time to be more wary in the future. The ophthalmoscope is sometimes employed for the early detection of the disease. When retinal congestion and miliary granulations within the eye can be demonstrated, all doubt is removed. But some cases of meningitis are unattended by retinal changes, and then this test is valueless.

But by the fifth or sixth day, if not sooner, the symptoms become so pronounced and characteristic as to compel a reluctant revision and correction of the diagnosis, if we have previously been mistaken. The inflammation, now fully developed, progresses rapidly. The headache increases. Children who are old enough often cry out, "My head, my head!" Why the pain should often be referred to the top of the head and the forehead, when the inflammation is mainly at the base, I do not know. In some instances the ear, the back of the neck, or, curiously enough, even the abdomen, is the seat of excruciating pain.

Characteristic symptoms of this middle period are found in the pulse and respiration. Slowness and variability distinguish the pulse. A decline of twenty or thirty or more beats is not unusual, but it does not remain constant to any figure, being slower at one time and faster at another. It is also irregular as to rhythm and strength. In many cases there is a lapse of every fourth, or sixth, or eighth beat. It is affected by slightest causes, and a trilling movement or excitement will surprisingly increase its rate. The slowing of the pulse is not, I believe, present in every case; but variability and more or less irregularity are, so far as I know, constant symptoms at this period.

Irregularity and inconstancy also mark the breathing during this middle stage of meningitis. One moment the inspirations may be equal and natural; at another they may cease altogether, and that for so long as to excite fears of a permanent suspension of the function. This will be followed, perhaps, by a hurried gasping, as if to store for time lost. Occasionally there is a deep and prolonged inspiration—a sigh. Yawning is likewise a frequent symptom. These peculiarities of pulse and respiration are doubtless due to the fact that the roots of the pneumogastric nerves are involved in the morbid processes.

The general surface of the body is pale—so pale frequently that it looks like white marble, while upon the cheeks and forehead, and perhaps the ears, appear, at irregular intervals, bright red and distinctly circumscribed spots of congestion. These spots upon the cheeks approach the circular in form, and are from an inch to an inch and a half across. They come and go in a wholly uncertain way.

Sometimes fugitive streaks of redness flit across the pale face as fleecy clouds move over the face of the clear moon.

These spots of congestion are in striking contrast to the general pallor of the features, and contribute to give to some infants, while lying quietly in a stupor, a look of health not only, but of great beauty.

When awake, the child is oblivious as to its surroundings. At one time there may be a steady, fixed gaze into vacancy, and a well-guarded silence, giving place, when disturbed, to a spiteful look and a petulant cry; at another time there may be an active, garrulous delirium.

By degrees the eyes assume appearances that signal the work of destruction going on within the skull. One of these is a permanent squint affecting one or both. When in a stupor, the balls, turned upward under the drooping lids, may be seen to move with feeble oscillations. From time to time the lids lift and quickly fall again. The pupils, contracted at first, are now dilated, probably unequally so.

In many cases the extremities are very cold, while the extreme heat of the head is made evident to the hand, but these are not constant symptoms.

There is a curious and unexplained symptom mentioned by most writers; that is, retraction of the abdomen. The bowels seem to retire toward the backbone, making a deep, tray-like excavation, above which the iliac and pubic bones and the cartilages of the ribs rise up like promontories. This condition is spoken of as the "boat-shaped abdomen." It is said to be present at some time in almost every case, and may appear early or late in the disease. If there is coexistent tubercular peritonitis, it will, of course, be absent.
PLANT: LECTURE ON ACUTE MENINGITIS.

During this middle period of the disease many children utter at frequent intervals a solitory, sudden cry, half scream and half squeal, so peculiar and characteristic as to have received long ago the name of “hydrocephalic cry.” Meningitic cry would be a better term.

Jerking of muscles, before alluded to as a frequent feature of the invisible stage, becomes more marked in this. Through it, counting of the pulse may be interfered with, and the face may be thrown into momentary grimaces. Tremors run through the frame, and tonic contractions cause rigidity of certain parts. Sometimes the head is drawn and held back, but to a moderate degree only, by stiffness of the unelastic muscles.

Gradually the increasing stupor merges into coma, paralyses of various parts supervene, and we pass, by insensible degrees, into the third and closing stage. General and special sensibility are now abolished, and the child can not be roused from its lethargy. The strabismus continues and the eye-balls become lazy, because no longer kept moist by winking. The pupils become more dilated, and entirely unresponsive to light.

Flakes of lymph collect on the margins of the lids and at the inner angle of the eye, requiring frequent removal.

The pulse, but lately so slow and halting, is now bounding along at a reckless, but more regular and equal pace, making often in the last days from 150 to 200 strokes a minute.

The breathing, too, like the pulse, but later, becomes rapid and more regular. Toward the end it is apt to become very noisy from tracheal and bronchial rales. Convulsive and automatic movements continue in parts that are not paralyzed. Chewing and sucking, and up and down movements of a leg or an arm, are common. The sphincters of the bladder and rectum becoming paralyzed, the urine dribbles away, and an offensive looseness follows the constipation of the earlier periods. Hemiplegia sometimes occurs; I have known one leg and arm to lie motionless for some days before death. General convulsions are imminent, and may bring the sad scene to a sudden close. But in most instances death lingers. The coma and insensibility become absolute; the pulse disappears; respiration becomes more labored and noisy; a copious sweat stands upon the surface; the lividity deepens, and, after several days of watching for the end, the child dies quietly. Authors assert that there is occasionally an unexpected waking from profound coma, when the little one recognizes its friends, and even handles its toys, but only to fall back, after a few hours at most, into a lethal sleep.

The ordinary duration of tubercular meningitis is between one and three weeks, but it may be so violent as to destroy life in two or three days, or so mild as to continue for many weeks.

The prognosis is the gravest possible. So few cases of recovery have been put on record that these have been considered by many as open to a suspicion of mistakes in diagnosis. It is true that trivial disorders of digestion do in some children create symptoms that simulate pretty closely those of meningitis, and that the cerebral and nervous phenomena of typhoid fever and pneumonia have often led practitioners into error. But the probability that attacks of real tubercular meningitis have been recovered from is strengthened by the fact that in quite a number of instances the children have subsequently succumbed to this disease or to phthisis pulmonalis. If we count all the reported recoveries as genuine, the showing, after all, is but a sorry one.

After the middle period, I think you will never be mistaken in prophesying a fatal ending.

A few words as to the simple or non-tubercular form. It is, as I before intimated, rare as compared with the other. It is as frequent in adults as in children, and, as it will be fully treated of from the chart of practice, I shall give but little space to it. It is less regular in its course than the tubercular form, and is frequently more rapid and violent. When it occurs from injury to the head, or from the extension of inflammation from other structures, as the ear, there may be almost at once convulsions and other symptoms of the fully developed disorder, and in three or four days, or even less, it may run its fatal course.

The inflammation is apt to be more diffused than in the other form, and after death the convexities of the hemispheres and their inner surfaces are usually found overlaid with pus and fibrinous membrane. Associated with spinal meningitis, it sometimes occurs epidemically, attacking large numbers of persons of all ages and conditions.

While the mortality of simple meningitis is very large, the prognosis is less certain than in the other form, since mild cases do occasionally end in recovery.

Treatment.—We now come to the discouraging matter of treatment. Everything has been tried with pretty uniform unsuccess. Up to a recent date the methods pursued with tubercular meningitis were not only heroic, they were torturing. Bleeding, local and general; large blisters or creton oil to the shaven scalp, and calomel, frequently in enormous doses—these were the agents employed to overcome and expel the demon. But they never did it, and most of the profession now advocate more humane if not more successful procedures. If you are so clever as to recognize the disease at its invasion, there is a little hope. The child should be kept quiet in a darkened room, and spared all occasion of annoyance and fretfulness. The diet should be as nutritious as the patient will take. Milk, cream, and meat broths are best. A hot foot-bath fortified with mustard lessens the cerebral congestion and soothes the child. I would use it as many as four or five times in the twenty-four hours. Keep the feet and legs warm by bottles of hot water, or other means.

Both reason and experience favor cold applications to the head. If there is a heavy growth of hair, it should be thinned, and cloths, not too thick, wrung from iced water and changed often so as to make constant impression of cold, may be laid upon the head. When there is intense heat of head, bladders of pounded ice may be applied. This is a powerfully depressing measure, and should not, I think, be used in infants or weakly children. When employed, some layers of cloth should come between the ice and the scalp.

Correct constipation by any agreeable laxative, but be chary of much physic, for the chance of success is not made better, but rather the worse, by hypercatharsis.
About the only drug that seems to have anything in its favor as making for recovery is iodide of potassium. Rooser suggested it in 1840. It has been extensively used since then with occasional benefit, or apparently so. Quite a number of cases of recovery under it, but discouragingly few as compared with the whole number of cases, have been reported from entirely trustworthy sources. It should be early and continuously given in doses of from 1/2 to 3 grammes—2 to 5 grains. To relieve the headache and ward off convulsions, bromide of potassium is our best remedy. When there are extreme restlessness and discomfort, you will find it of service to combine chloral and bromide. Ordinary doses will often fail of appreciable effect. Give them boldly until your purpose in giving them is effected. Valerian, in fluid extract or other form, tends to quiet the muscular twitching and the general restlessness. In most cases it is better to dispense with opiates, since they increase cerebral fullness, constipation, and the growing tendency to stupor. But in certain cases the agony is so great that they may, and should, be freely used, even hypodermically.

By the early and persistent employment of such means as these you may possibly save your patient, and then, in your surprise, you will ask yourself whether, after all, your diagnosis was not erroneous.

The prophylactic treatment of tuberculous meringitis promises more than the direct. To prevent so terrific a malady is better than to cure it, even if we could cure it. A child with inherited tuberculous or serofulous tendencies should be well looked after, especially if it begins to exhibit those vague but growing evidences of poorness that are so often precursory to this affection. Cod-liver oil should be given, a half-teaspoonful or more t.i.d. The diet should be nutritious—the best that can be digested. Stimulants are in order—bourbon or brandy with milk. Mild exercises out of doors, that interest and amuse without fatiguing, should be provided. Change of air and scene is often of signal service. If there are moist eruptions about the head and face, I would not attempt to dry them by local applications, but rather trust them to disappear with the improvement in the general condition.

REMARKS ON THE TREATMENT OF IRREDUCIBLE HERNIA BY OPERATION.

By WILLIAM T. BULL, M.D.,
SURGEON TO THE NEW YORK AND ST. LUKES HOSPITALS.

With the confidence inspired by success with antisepic wound-treatment many surgeons have been encouraged to revive operations which had been discarded, and to perform them with success. Among such none have attracted more notice than the operation for the radical cure of hernia.

Various methods of operation, involving the incision and subsequent suture of the structures concerned in ruptures, have been adopted, and have yielded a varying degree of success. Leaving out of consideration minor modifications, these methods, which have been termed "modern radical operations," may be reduced to three—viz.: 1. Closure of the abdominal aperture of the hernia (Steele and Marcy). 2. Closure of the neck of the sac by ligature or suture (Nussbaum). 3. A combination of the two procedures (Czerny).

Reports of operations and a number of papers have accumulated the experience of nine years, and we can form a good notion of the value of these operations by studying the elaborate statistics compiled by Dr. Leisirink, of Hamburg. It will be sufficient for my purpose to call attention to the results of the operation for all cases not strangulated—i.e., reducible and irreducible. Of these there have been operated on, by one or the other method, 202 cases (169 inguinal, 25 femoral, 8 umbilical and ventral), with 15 deaths, which gives a death-rate of only 7.4 per cent. Nine deaths were due to septic poisoning, which represented a death-rate of 4.4 per cent. from this cause. The percentage of relapses, or cases in which no cure was obtained, is large. Details are not given in all cases, but of those reported there are found 20.4 per cent. of relapses. Of thirty-two patients who experienced relapse, a decided improvement was claimed in 80 per cent. Of the patients operated on for inguinal hernia, in 60 per cent. it was irreducible.

These figures show that the operation is attended with danger (7 per cent. mortality, 4.4 per cent. deaths from sepsis), and that it fails to effect cure in 20 per cent. of the cases, while at the same time it holds out decided hope of improvement. It can therefore hardly be recommended to patients with hernia that can be controlled by a truss. These persons are comparatively comfortable with a truss, and their condition is free from danger, if they exercise proper care; and, if any operation is attempted for their cure, it should be one without risk, such as the cure by Heaton's method of injection. The subjects of irreducible hernia, on the other hand, or at least a large majority of them, suffer frequent inconvenience, and are in constant danger of serious accidents. If the hernia contains intestine they are generally unable to wear a truss, and have dragging pain on exertion, and frequent intestinal disturbances. They are liable to inflammation of the protruded viscera, or to the occurrence of strangulation of additional intestine. With an umbilical hernia some persons can wear a truss, especially if the pad be "concealed"; but they rarely do this with comfort. Without its support there is generally a feeling of weakness, inability to make more than moderate exertion without pain, and there is just the same liability to or danger of the accidents of strangulation or inflammation.

These are the cases for which I believe the modern operations are desirable, and should be recommended when the simpler measures—such as rest in bed, restricted diet, * Read before the New York Surgical Society, November 27, 1883.

* For the literature of the subject we should consult "Die moderne Radikal-Operation des Unterleibsrisses," by Leisirink. Hamburg: Leopold Voss, 1883.
repeated taxis and compression of the hernia—have failed. I have operated in all the cases which have come under my notice in the past three years, and with success. They are three in number.

Case I.—Irreducible Inguinal Ocental Hernia; Excision of Omentum, Ligature and Excision of the Sac; Recovery.—A housekeeper, aged forty-seven, in good general health, was sent to me by Dr. Gibney for an irreducible inguinal hernia of the left inguinal region of six weeks' duration. The rupture had existed for ten years in a reducible condition, and had never given any annoyance till it became fixed, when the presence of a truss became unbearable, and she had pain on making moderate exertions. Several ineffectual attempts to reduce it without anaesthesia had been made. The swelling was over the site of the external abdominal ring on the left side, of the size of a small egg, doughy in feel, dull on percussion, tender on pressure, and no fluid was found on puncture. Her general health was unaffected. After four days' rest in bed, with poultices applied at frequent intervals, the tenderness disappeared, and the swelling became softer. An attempt to reduce it under ether did not succeed, and an operation was recommended. On March 8, 1882, she entered St. Luke's Hospital in the same condition as before. Under ether and with the spray the sac was opened by an incision three inches in length and, found to contain a mass of omentum adherent to the sac at some places. At the neck of the sac it was as large as the little finger. It was drawn down, tied off with a carbolized-silk ligature, and the stump returned to the abdomen. The sac was then pulled down, its neck sewed up with fine catgut, and the rest excised; the wound was united by a few catgut sutures and one silver wire, with lead plates. A carbolized-peat dressing was applied. Recovery was interrupted by a retention of secretion in the wound, which gave rise to slight fever, local tenderness, and vomiting on the third day. These symptoms disappeared promptly on relieving tension by opening the skin wound, and the entire wound healed by granulation under carbolic-acid compresses, without further general or local disturbance, in four weeks. Six months afterward, though the woman had discarded the truss given her on leaving the hospital, there was no sign of return and no unpleasant symptoms.

Case II.—Irreducible Inguinal Ocental Hernia, extending into the Labium Majus; Excision of Omentum; Ligature and Excision of the Sac; Recovery.—A widow, thirty years of age, and a seamstress by occupation, had been prevented from going out of the house, and at times even from moving about the room, for six months before she was sent to me from the Hospital for the Ruptured and Crippled. The rupture appeared three years before in the left inguinal region as large as a pea, and had gradually increased to the size of a man's thumb without ever being reduced. It gave her little trouble till about six months before I saw her. At this time she consulted a truss-maker, who made repeated efforts to fix a truss over the swelling, which he called a "gland." She could bear no pressure, and was unable to move about freely without pain. The swelling was three inches in length, extending from the external abdominal ring into the labium of the left side, irregular in its outline, soft to the feel, dull on percussion, irreducible, but giving an impulse in coughing at the upper part, and tender on moderate manipulation. Her general health was good. An operation was recommended, which was performed at St. Luke's Hospital, April 6, 1882. This operation was without spray, but with other antiseptic measures. The incision, three inches in length, exposed the peritoneal sac, which was opened and found to contain a tongue-like process of omentum, which was atrophied opposite the neck of the sac. This was tied with carbolized silk just about its thinnest part, cut off, and the stump returned to the abdomen. The hernial sac was then isolated, drawn down, its neck ligated with catgut, and the wound in the subjacent tissues of the labium extended through the greater part of the labium majus. Six sutures were put in the upper part of the wound, which was now four inches in length, the lower part being placed in apposition by small peat-bags (with iodoform). A peat and iodoform dressing was applied. The wound healed under two dressings, except a narrow granulating strip, which was excised by the twelfth day. A truss with a light spring has been worn since, though there is no protrusion, and the patient feels perfectly well.

Case III.—Inflamed Irreducible Scrotal Hernia (Epiplocele); Drainage of the Sac; Antiseptic Treatment with Spray; Recovery.—A laborer, aged forty, came to the Chambers Street Hospital suffering from abdominal pain and vomiting, which had begun twenty-four hours before admission. He called attention to a large scrotal hernia of the right side which had been irreducible for five years. How long it had existed he could not tell. The hernia was of the size of a coconut, and covered the upper third of the thigh. There was no tension, and the finger could be passed into the abdominal aperture on its upper surface. The surface was smooth, and tympanitic over the lower part; it was dull and doughy above. It was not decidedly tender. There was no impulse, and no impression could be made on it by taxis, but "gurgling" was produced. The man could not tell whether it was any larger than it had been for years past, but thought it got larger while he was at work and before the vomiting began. He had slight abdominal pain, no tympanites, pulse 100, temperature 99° F., surface warm. He had been constipated for several days, but it was his habit, and he paid no attention to it. He stated, too, that he had had several attacks like this before, lasting two or three days. At the expiration of twelve hours morphia had been injected hypodermically three times, and ice applied to the tumor, and his condition was about the same. He had, however, omitted several times, but only the contents of the stomach. Fearing the approach of strangulation, I decided to attempt taxis under ether, and, this failing, to cut him. Taxis was tried for fifteen minutes without success. An incision three inches long was then made, and the tissues external to the sac divided. Taxis was again tried unsuccessfully. There seemed to be, however, no constriction about the neck of the sac, for the finger could be passed into the abdominal ring. The incision was extended, the sac opened, and found to contain some turbid serum, not offensive, a loop of large intestine slightly congested (it was barely changed in color) and distended with gas, and some small intestine not congested, forming a mass as large as a big fist, which was adherent to the bottom of the sac. It was held in a club-shaped mass by adhesion of the serous coats at its narrowest part. These bands and the adhesions to the sac were torn through, and about twenty carbolized-silk ligatures applied to bleeding points. Both loops of intestine were then replaced. The abdominal ring admitted all the fingers, and the tissues overlying the sac in its vicinity were adherent and thickened. I therefore did not ligate the sac, for fear of injuring the spermatic cord, nor attempt its extirpation, in order not to extend the wound into the cellular tissue of the scrotum. But a counter opening was made at the bottom of the sac and the wound sutured with silk, two drainage-tubes being inserted. Lister dressing was applied. There was but slight shock from the operation. The wound healed entirely in four weeks, with but moderate suppurition and slight fever (101.5° F.), but there was marked local peritonitis from the sixth to the tenth day. The bowels moved on the second and fourth days naturally, and there was no more vomiting. The man was discharged at the
end of two months, wearing a Heaton bandage, and has not been heard from since.

It will be noticed that I have followed only the one method, that of ligature and excision of the sac, and that is the only one, from what I have read of the operations of others, that I should be willing to recommend. The apertures cannot be first pared and then sewed up without increasing the risk of the operation, and, from what we know of the liability to ventral hernia after wounds of the muscular parietes, there is no reason to believe that we can effectively close up an orifice surrounded by aponeurotic structures. I see no objection to the attempt to diminish the size of the orifice in this way, but I believe it of doubtful efficiency. I should think it wisest to adopt the safest operation for an irreducible hernia, which will make it reducible. A truss will then control it, and at a later date I should endeavor to diminish or to close the abdominal aperture by the injection method.

While the statistics quoted above give one a general idea of the risks of the operation, it will be apparent to all that these will vary with the conditions of each individual case. A small small hernia in a woman is a safe thing to cut into, and a large intestinal hernia in a man a very dangerous one. In the same way the ligature or the excision of the sac in one case may add a trifling risk, in another a very great one. Drawing down the peritoneal pouch, cutting it across, and causing it to unite, is the chief object to be accomplished. The remainder can be left (and drained) if its removal would leave a wound with many chances of septic infection. If not, it should be excised.

I have spoken of this operation only in connection with irreducible hernia. It is proper, however, to state, before closing, my convictions as to its employment in strangulated cases. Leisirn's tables show the mortality after operations for strangulated hernia to be as follows: Of 186 cases, there were 33 deaths, giving a mortality of $17\frac{3}{4}$ per cent. This compares most favorably with the rate of mortality in the days before antisepctic surgery was adopted; for the statistics of Luke, Maligne, Textor, South, and Gosselin show a death-rate varying from 32 per cent. to 80 per cent. As to the duration of the strangulation, the modern operations with antisepctic treatment show:

Twenty-three cases operated on within 50 hours, 2 deaths, $8\frac{3}{4}$ per cent. mortality; 21 cases operated on after 50 hours, 7 deaths, 33\frac{3}{4} per cent.; while with the older methods we find (Gosselin's statistics) 25 cases operated on within 50 hours, 8 deaths, 32 per cent.; 41 cases operated on after 50 hours, 23 deaths, 65 per cent.

This, indeed, convinces me that it is safe enough to add to the ordinary operation for strangulated hernia the measure I have referred to above. In other words, I would urge ligation or suture of the peritoneum at or above the neck of the sac in every case of strangulated hernia, and excision of the sac besides, or its drainage, according to the circumstances of the case. In four operations performed within the last two years—three for inguinal and one for femoral hernia—I have both ligated and excised the sac; and the wounds have healed promptly and without constitutional disturbance.
got well spontaneously, and, one year later, the sac was
still dry.

In hydroceles of adults I have noticed, with few excep-
tions, what is not noticed in the text-books, that an
induration of the epididymis co-exists, either as a hardness of its
entire body, or of the globus major or minor alone, showing a
very subsutate, painless, inflammatory action. This can be
noticed only after tapping.

A word regarding encysted hydroceles.

These are developed in the cellular plane investing the epi-
didymis, and probably originate from an obstructed seminal
duct. The fluid is invariably as colorless as water (strongly
in contrast with the straw-colored fluid of the ordinary va-
riety), or slightly milky from the spermatozoa in suspension,
which soon form a sediment on standing. In some cases we
find, on microscopical examination, living spermatozoa.

The encysted hydrocele is said to be almost always small
—half an ounce to two ounces or so—though Curling says
he has seen one as large as twenty ounces.

Among quite a number of this variety I have seen two
much larger than that—one of thirty-eight ounces, and
another enormous one of forty-eight. The latter was in a
man of fifty years; had developed during five years; color-
less fluid; spermatozoa in action. Waited two months
after tapping, till it had filled to fifteen ounces. When, after
lapping, I injected half an ounce of tincture of iodine. One
year later no trace of fluid or thickened sac remained. It
was cured. In the patient sixty-three years old, with a
thirty-eight-ounce hydrocele of this form, of seven years’
standing, there was one of three ounces on the other testicle
also. Spermatozoa were abundant in the fluid. One drachm
of tincture of iodine was thrown into each sac after tapping,
and a little inflammatory fluid returned in a month or so, as
is usual, but was reabsorbed, and, one year later, both sacs
were dry.

Thus, as I have found in smaller encysted hydroceles too,
Curling’s statement, that this form is not cured by iodine, is
disproved. I think, in fact, that its cure is almost certain.

This variety I have found exclusively in old gentlemen
from fifty to seventy years. In one patient of seventy it
began fourteen years before, immediately after his wife’s
death, when he became continent. It grew to fifteen ounces;
fluid colorless, spermatozoa abundant.

A number of smaller encysted hydroceles have remained
as perfect cures by the iodine injection.

Dark fluid hydroceles are apt to contain either blood or
cholesterol, and I have thought the former sometimes de-
generated into the latter, as illustrated by a twenty-five-
ounce cyst in a patient of seventy years, giving a sediment of
blood and spermatozoa and sperm cells when tapped in
October, 1879, but when next seen and tapped, in June,
1883, yielding fluid containing cholesterin crystals in abun-
dance. Suppuration of the sac followed simple tapping, and
a small slough occurred at the puncture point.

I have seen two cases of thickened sac, with cholesterin
crystals in the fluid, suppurate freely after tapping, and be-
lieve the irritation of the crystals escaping in the course of
the puncture set up irritant action. This accident, however,
does not always follow evacuation of such fluid, as shown in
a ten-ounce hydrocele carried eight years by an old gentle-
man, the fluid of which deposited one fifth of its bulk of
crystals. No suppuration followed tapping.

Curative Treatment.—First. By internal administra-
tion of iodide of potassium in selected cases, cure may be
brought about after tapping, where there is well-marked
induration of the epididymis. The power of this drug to
produce absorption of plastic exudation or chronic indura-
tion is well recognized, even where (as is most often the
case) there is no syphilis suspected. Of course, if this dis-
case does exist, potash must be used. I have record of a
case of double hydrocele, ten ounces on each side, where
the testicles were both somewhat enlarged and hard. The
man proved syphilitic, and but one tapping, followed by
medicine, cured him.

Second. Injection with iodine will, if rightly used, be a
competent curative method in most cases. I have resorted
to it about forty times, and note the following points:

There is almost always some little shock after injection.
The pulse commonly falls from 80 to 60 or 50 beats for a
few minutes. Some pallor is usually shown, and a good
deal of pain experienced, following the course of the vas
derbers.

I have once seen very profound shock. The patient was
sixty-six years old, and had an old hydrocele of ten ounces,
which I evacuated, and had injected but half a drachm of
iodine when the patient showed prostration, pallor, and
collapse; became pulseless, and was restored only after half
an hour of stimulation by whisky, ammonia, and hot bottles.

I should prefer not to use the iodine injection in a pa-

tient with weak heart.

Occasionally, for some unaccountable reason, a case is
utterly rebellious to this method of cure, as in a man of
twenty-one years, whose hydrocele had been injected with
iodine, three times in seven years, by Dr. Fowler, of Albany,
and Dr. Otis, of New York, and no impression was made on
it. To test the matter, I did it with thoroughness the
fourth time, and also failed to cure it.

After iodine injection one expects first an accumulation
of some inflammatory fluid, rapid for a week or so, then
slow, and finally a reabsorption, leaving the sac dry.

Third. Injection with pure carbolic acid, as demon-
strated by Levis, of Philadelphia, has taken rank as probably
the best method of radical cure of hydrocele.

I have resorted to it in about a dozen cases, and find
that its two decided advantages are, that it gets up a grade
of plastic inflammation different from and better than that
by iodine, and that it is almost always painless and gives no
shock. The pulse never varies after the injection. I have
had but one man complain of pain, and he for three minutes
said his “testicle felt as if it was in a frying-pan.” After
operation the patient usually keeps at his work. There is
less reaccumulation of fluid, and more often a plastic lym-
ph that can be felt in the sac.

One drachm of deliquesced crystals should be thrown
through the cannula, distributed in the sac, and left.

The scrotum should be well greased, to prevent the causti-
c action of the acid on the skin if a drop or two of it es-
 capes from the cannula.
I once injected three drachms into a large sac and had acute suppuration follow, requiring incision, which, of course, cured the hydrocele effectually. I used too much. One drachm will always suffice. Carbolic-acid poisoning never follows this injection.

Finally, I regret to report one death following the simple operation of tapping without injection.

An old and feeble book-agent of temperate habits of life was tapped by me three times in 1879 for a hydrocele of twelve ounces. No reaction followed, but in the next year, after a simple tapping, there ensued acute inflammation of the sac, and phlegmonous cellulitis of the scrotum, with fatal exhaustion, due to his enfeebled condition.

It was the only serious result of over one hundred and fifty cases, representing, perhaps, five hundred tapping.

VULCANIZED PESSARIES FROM PLASTER-OF-PARIS CASTS.

By C. A. Lee Reed, M.D.

Professor of Obstetrics and Gynecology in the Cincinnati College of Medicine and Surgery.

In an issue of the "New York Medical Journal" some months ago there appeared the synopsis of a report by Dr. Dawson, of New York, on "Plaster-of-Paris Pessaries." The method employed by Dr. Dawson, according to my recollection, consisted in packing the upper portion of the vagina with absorbent cotton saturated with a mixture of plaster of Paris in water. This packing was permitted to harden in the vagina, when it constituted a firm, efficient pessary fitted to the parts it was intended to occupy. The procedure impressed me favorably as embodying the principle of adjusting a pessary with such nicety that it would not distort the vagina and interfere with nutrition by exerting undue pressure at any particular point. I accordingly adopted the suggestions of Dr. Dawson in my practice, but I soon discovered that the very principle for which he contended was defeated by the methods he employed—or, at least, that I employed in accordance with what I remembered to be his suggestions. The act of packing the vagina implies the application of a pressure which, if persistent, as in the case of a pessary, becomes, or is liable to become, the source of serious trouble in the cellular tissue. But other objections soon became manifest:

1. The method of application implied and effected undue distortion of the vagina and adjacent tissues.
2. As a consequence of the foregoing, nutrition was disturbed and cellulitis was sometimes developed.
3. The pessaries thus formed absorbed secretions to such an extent as to become fetid and septic in a remarkably short time.
4. In cases of dilated vagina, the amount of material required to form a pessary that would be self-retaining was so great that its weight became an objection to its use.

To overcome these objections, and yet take advantage of the principle of scientific adjustment, I was induced to apply the plaster in a different manner. A mixture of plaster of Paris in water was made of such consistence that it could be readily drawn into the barrel of a metallic syringe, the distal end of which had been cut off for the purpose. This instrument, loaded with the plaster, was passed into the vagina by the aid of a sinus's speculum and the plaster discharged, the syringe being gradually withdrawn as the plaster was projected into the vagina. The patient was kept in the recumbent posture until the plaster had had time to "set." In subsequent cases I avoided this detention in bed by packing in the bottom of the syringe some dry absorbent cotton, which was discharged with the plaster, and which formed an effectual plug, serving the threefold purpose of preventing the escape of the plaster from the vagina, forming a cushioned lower extremity to the plug, and preventing the formation of disagreeable sharp corners. After twenty-four hours the plaster was removed, the cotton torn away, and a hole drilled lengthwise to permit of cervical drainage.

The object in applying the plaster in this form was to have a mass that, when thrown into the vagina, would yield to the natural contractility of the walls of the canal and thus become adjusted strictly in situ natural. In this I succeeded, so that when the pessaries were returned, after being perforated as indicated above, they were invariably worn without the slightest difficulty.

They, however, became fetid, and in some cases were too heavy. To overcome the former objection I coated them with shellac, but that failed to prevent absorption. Then, to overcome both the absorption and the weight, I concluded to use the plaster pessary as a mere cast, which I took to a dentist and had reproduced in rubber just as he would vulcanize a plate for a set of teeth. The result was a pessary with which I was satisfied, and the development of a line of practice which I have since found of great value.

A few final observations may be of interest to those who may have a fancy to try this line of practice.

1. In cases of displacement the uterus should, of course, be replaced before the plaster is applied.
2. This treatment is utterly impracticable in those cases of version and flexion in which there is not sufficient cervix within the vagina to afford leverage.
3. As a rule, the attempt to take a plaster cast of the vagina should not be made in cases of cellulitis, although I have seen mild cases of this sort decidedly benefited by the procedure. The plaster is a powerful astringent and an efficient alterant.
4. Ordinary cases of vaginitis offer no obstacle to the use of the plaster. I sometimes treat cases of vaginitis with a vaginal plug of plaster of Paris.
5. The plaster should remain in the vagina until the secretions have overcome its astringency, when it can be removed without violence to the epithelium.
6. Care must be taken in applying the plaster that no rough corners or horns are formed, as they are embarrassing complications in effecting the removal of the cast. If the manipulations are properly made, there is no danger from this source.

The Pharmacopoeia as a Legal Standard.—A Boston firm of druggists has been fined for selling tincture of opium containing a smaller proportion of morphine than is prescribed by the pharmacopoeia. It is said that an appeal will be taken to a higher court.
TWO CASES OF
FATTY DEGENERATION OF THE HEART,
WITH REMARKS.

By CHARLES R. CRANDALL, M.D.,
PORTLAND, ME.

Case I.—John B., aged fifty-four, a farmer by occupation
and of temperate habits, had always enjoyed good average
health up to two years before coming under observation, when
he had an attack of kilipathetic erysipelas, which lasted for sev-
eral weeks. His recovery was slow and imperfect, and he felt
that his general health had been much impaired. Three months
previous to my seeing him he had what was called a "slow
fever," and from this his recovery was also tedious. After
these attacks he never recovered what it was to be well, and he
suffered more or less from the following symptoms:

He had headache much of the time, and occasionally attacks
of vertigo; his breath was short, and would seem to fail upon
the slightest exertion or excitement; he had a constant sense of
failure about his heart, and at times vague and irregular pains;
he complained, besides, that he had palpitation and a sense of
fluttering in the region of his heart.

He was a great sufferer from acidity, vomited occasion-
ally, and had a badly coated tongue. These later symptoms,
accompanied by constipation, led him to believe that he was
"bilious" all the time, and induced him to make frequent use
of purgatives. The general surface of the skin had a shriveled
look, as if nutrition and circulation were both defective. The
veins about the forehead were prominent, while those of the
lips were also full, giving a eumyosed appearance to those sur-
faces. There was a well-defined area senilis upon the corners
of either eye.

The action of the heart was slow, as indicated by a pulse of
sixty, and the first sound was feeble, while the second was well
marked. There were, however, no valvular murmurs or lesions
of any description. Upon percussion, it was found that the size
of the heart was rather above normal, which I attributed to
either the hard work he had done in the past or else an accu-
mulation of fat.

The percussion note at the base of both lungs was slightly
dull, which I explained on the theory of venous stasis due to
impaired circulation. There were some moist rales in the larger
bronchial tubes, but beyond this the lungs were in fair con-
tion. The kidneys were normal, and the quantity of urine ap-
proximately about what should be expected. There had never
been evidences of dropsy in any portion of the body.

The general condition of the patient was that of feebleness
and general decline. He returned to his country home, and the
termination of his case is not yet known.

Case II.—Mrs. L., a married woman, aged sixty-seven, hav-
ing a family grown, was large of stature, rather corpulent, and
of a good history of general health up to within a few years. I
was called to see her early one morning, and found that she had
had several attacks of vomiting during the night, chilly sensa-
tions, more or less cough, profuse expectoration of frothy mu-
cus, and a sense of fullness and pressure under the sternum and
in the right lung. Her breathing had been rapid and difficult,
and there had been a sensation in the region of the heart which
she characterized as "a strange feeling" and "a weakness." I
noticed that her cheeks were somewhat flushed and that her lips
were dejectedly blue. Looking into her eyes, I detected a well-
defined area senilis in the corners of each eye. Her pulse was
feeble and running at the rate of about sixty-five a minute.
The extremities were cool, and the flesh yielded a decided sense
of flabbiness to the touch.

On auscultation of the heart, I heard a soft, feeble first sound
and a fairly marked second sound. There were no cardiac mur-
murs or other evidences of valvular lesions. Macous rales were
abundant in the lower portion of the right lung, while the left
seemed to be in a nearly normal condition. The percussion
note at the base of the right lung was somewhat diminished.
The temperature was normal, and there were no symptoms of
inflammatory action.

I treated her for congestion of the lungs due to heart failure,
and she recovered to a considerable extent in three or four days.
Her convalescence, however, was slow, and she suffered very
much from general debility and shortness of breath. At times
her breathing would be very feeble and irregular, and at other
times would almost stop, and then become quite strong again.
She complained a great deal of strange sensations in the region
of the heart. At times there would be over-action, and again
the sensation would be that of failure, as if the organ were about
to stop. Moreover, she complained of coldness of her limbs,
"creepy sensations" down her back, and of "tingling and numbness"
in her left arm. One day she told me very confi-
dently that at three different times during the last two years
she had had "strange spells" which made her believe she was
losing her mind. Each "spell" had occurred when she was out
walking and had become rather tired. Upon each occasion her
vision became dim, her mind confused, her breath short, and
her limbs weak, and she would try to get somewhere to avert
what seemed to her was impending death. So soon as she could
sit down and get rested this alarming condition would pass
away, and she would find herself panting for breath and her
heart palpitating rapidly.

Under continuous treatment this patient has steadily im-
proved, and has had a year of very satisfactory health.

My diagnosis in each of these cases was fatty degeneration
of the heart, and it was based upon the signs and symp-
toms present as well as upon the general laws of the
disease. But, before going into the symptomatology of
this disease, let us note the meaning of fatty degeneration.
As the term implies, the structure of the heart degenerates,
and in time certain portions are transformed into an oily or
fatty material. The initial point of degeneration is along
the longitudinal fibers and within the substance of the
muscle. At first the deposits of fat are microscopic in size, and
appear as globules of oil or fat distributed along the fibers
of the muscle. "It is usually most noticeable in the inner
layers of the myocardiun, which are particularly prone to
fatty degeneration." With the advance of the disease the
globules of fat increase in size, followed by a diminution
and degeneration of the true muscular structure. In the
early stages the deposits of fat may be more or less local-
ized, but in advanced stages of the disease the entire organ
may be involved. With increase of the fat the color of the
organ undergoes change. Excess of fat in spots may give
it a sort of mottled appearance. In advanced cases, where
there is general involvement, there may be a paleness about
the organ, or a "yellowish-brown, or buff, or muddy-pink
color." When degeneration has gone on sufficiently far
the consistence of the organ is markedly changed; it be-
comes soft and yielding, and, in advanced cases, the tissue is
so utterly destroyed that it will break or mash down under
pressure. Such are some of the gross lesions found in a
well-marked case of fatty degeneration of the heart.

Returning now to a consideration of the causes and
symptoms of the disease, I will say that in both of my cases the age of the patient was sufficiently great to assign it as a predisposing cause. Fatty degeneration of the heart is most common between the ages of fifty and seventy. Watson teaches that it is most common at about the sixty-third year. Of eighty-eight cases collected and analyzed by Hayden, the larger number was between the ages of sixty and seventy.

Obesity is considered to be another predisposing cause. While it is not a cause upon which much stress can be laid, nevertheless, as my female patient was corpulent and flabby, I accepted that condition as a predisposition to the disease from which I believed she was suffering. Thus both patients had predisposing conditions which would naturally form powerful factors in diagnosticking fatty degeneration.

Both had indistinct first heart sounds, accompanied by a generally weak and irregular condition of the entire organ. Nearly all authorities lay much stress upon these physical signs when accompanied by the other general symptoms of fatty degeneration.

In regard to this point Da Costa has said: "We may, however, suspect it [fatty degeneration] if the signs of weak action of the heart—feeble impulse and ill-defined sounds—coexist with a pulse permanently slow or permanently frequent and irregular, and be met with in a person who is the subject of a wasting disease, or who has arrived at a time of life at which all the organs are prone to undergo decay. Something more than a suspicion is warranted if, in addition, there be proof of fatty degeneration elsewhere, such as an arcus senilis."

An important symptom at times in both cases was irregular, rapid, and difficult breathing, which was attributed to heart failure. This symptom would naturally enough be present with a feeble heart, because the circulation through the lungs must necessarily be slow, rendering the condition most favorable for venous stasis. In case second the irregular breathing was at times of the peculiar kind known as "Cheyne-Stokes dyspnea," or "the ascending and descending respiration." So common is this form of dyspnea in fatty degeneration of the heart that it was for a long time considered characteristic of the disease, but at present it is only admitted as corroborative evidence when found associated with other well-marked symptoms. As before intimated, the second patient had at times a tendency to syncope, which is a condition more or less associated with a fatty heart. The remarks of two eminent authorities on this symptom are especially worthy of citation, for they tend to explain in some degree why it is that elderly people often have "fainting spells," or have attacks which they dread as being precursors of apoplexy. Da Costa says that these patients may be "subject to seizures, during which their respiration seems to come to a standstill: and that they are liable to be stricken down with repeated attacks having the character of apoplexy save that they are not followed by paralysis." And Flint directs our attention to the fact by observing that "these patients are liable to seizures resembling apoplexy, characterized by temporary loss of consciousness, without paralysis, the surface being pallid and cool and the circulation feeble."

Both patients had well-marked arcus senilis. The presence of the senile arc is not given the diagnostic importance it formerly was, but, when found in elderly persons in connection with the other symptoms herein referred to, it is worthy of consideration. It usually points to degenerative changes, but modern investigation has thrown open the view that it has a pathognomonic relation to fatty degeneration of the heart. It is now believed that it may occur either with or without degeneration of the heart.

Again, both patients suffered from indigestion and what they characterized as "biliousness." This is another common symptom belonging to the group of those having a diagnostic importance. It is believed to be due to impaired circulation resulting in secondary congestion of the stomach and liver. After this state exists for a time it causes a catarrhal condition of the mucous surfaces of the organs of digestion, and there result acidity, pyrosis, flatulence, and other well-marked symptoms of indigestion.

Lastly, both patients complained of pain and other strange sensations occurring in the region of the heart. In many of the cases of fatty degeneration of the heart, patients will complain of a "peculiar feeling," of "some pain and fluttering," of "a queer feeling," of a "sense of weakness or failure," or a "sense of suffocation." Others will add also that they have a sense of fullness under the sternum, pain and numbness in the arms, and "cold and creepy feelings" down their backs. These symptoms are often encountered in elderly people, and they should always be taken as suggestive of dangerous disturbance in the heart and circulation. While it may be said that there are no one or two symptoms that are pathognomonic of a fatty heart, when one comes upon a group like the foregoing occurring in an old person, there seems but little room left for doubt.

But few words are required regarding the prognosis. In one sense it is always unfavorable, while in another it is often made favorable by regulated habits and medical treatment, which aid greatly in prolonging life. But the rule is, that, as years increase, patients thus afflicted become feeble and steadily fail. At times they sink from intercurrent disease or wear out from difficult breathing, dropsy, and debility. Again, they die suddenly from cardiac syncope or else from rupture of the heart.

"Of eighty-three cases of fatty disease of the heart, collected by Quinn, sixty-eight died suddenly."

The treatment indicated is worthy of consideration, for, if well carried out, a valuable life may be decidedly prolonged.

1. Treatment should be supporting. Everything should be done to preserve muscular integrity and maintain vitality. Proper exercise, good food, fresh air, plenty of sleep, tonics and stimulants, make up the daily requirements.

2. Moderation in all things is a law that must be enforced. The penalty of its violation is rapid decline, constant distress, perhaps sudden death. Whatever exertion taxes the strength, causes mental excitement, or wearies the nervous system, may cause failure or a rupture of the cardiac walls.

3. These patients must not be housed up, for they need
the vitalizing effects of pure air, sunshine, and gentle exercise. These can be best obtained by short, easy walks and daily rides in an easy carriage. When seeking out-of-door life, exposure to cold and damp or excessive heat must be guarded against, for whatever disturbs the circulation, or prostrates, will imperil the diseased heart.

4. The diet should be nutritious and easily digested. Of the articles most appropriate may be mentioned skimmed milk, tender fresh meats, fruits, Graham or gluten bread. These are wholesome blood- and muscle-making foods, and have no special tendency to make fat.

5. Stimulants under such conditions are to be given judiciously, but nearly all these patients need them more or less. General debility and a feeble heart make a permanent demand for a mild stimulant which will help promote digestion and sustain the vital powers. In case second I found that a small quantity of sherry wine taken four times daily seemed of the highest utility in maintaining the force and regularity of the heart's action.

6. In regard to general indications for treatment, there is much to be looked after, for these patients generally suffer from shortness of breath, poor appetite, indigestion, anaemia, attacks of syncope, and headache. Hence there is the constant demand for strychnine, digitalis, caffeine, opium, iron, and quinine. These, together with wine and a regulated diet, will do much toward prolonging life.

Clinical Reports.

NEW YORK HOSPITAL.

CLINICAL REMARKS BY ROBERT F. WEE, M. D.

Saturday, November 10, 1883.

Depressed Fracture of the Skull; Topraphying.—Cancer of the Breast; Amputation.—Necrosis of Both Tibia; Removal.

CASE I.—GENTLEMEN: Before presenting the case for operation, I will show you a patient illustrating one of the conditions demanding the operation of trepanning. A man struck him on the head with a hatchet, cutting a gash more than an inch long and an eighth of an inch wide into the right parietal bone, near the median line. Through this opening depressed bone could be felt. No cerebral symptoms developed, and the question arose whether it was worth while to submit a man feeling perfectly well in every respect, and able to walk into the hospital, to trepanning, an operation attended, as you know, by considerable risk. You are doubtless aware of the fact that, in many cases in which the blow is concentrated, as in the present instance, the injury to the external plate may be slight, while a considerable portion of the inner plate may be fractured and depressed. The experiments of Tewson go to show that a pistol-ball perforating the skull cuts the outer table cleanly, while the inner table is a good deal shattered; but that, if the ball emerges on the other side of the skull, the inner table will be cleanly cut, and the outer table more or less fractured or splintered off. In the present case, believing that such a condition existed, with the double gouge, or rongeur, I removed sufficient amount of bone at the seat of the injury to enable me to discover a depressed piece broken off from the internal plate, measuring one inch by three quarters, resting on the dura. This doubtless would have given rise to serious trouble within eight or ten days had it not been removed. It was necessary to enlarge the opening farther before the piece could be removed, and then only in the manner I would always advise you to adopt—namely, after seizing the edge of the fragment with a strong dressing-forceps, or, better still, with a duck-bill forceps, making traction directly upward and outward, avoiding all tiling and twisting of the fragment. Moreover, do not try to extract it through too small a hole. By taking such precautions, you will avoid damage to the dura mater and the brain. After smoothing off the ragged edges of the opening, the wound was washed out with the sublimate solution and closed, and an iodiform dressing was applied; the patient has presented no symptom whatever since the operation, which was done a week ago. The wound has healed entirely, save where the small drainage-tube was placed. Iodiform is a very good dressing for small wounds of this kind; it does not have to be changed often, and there is only one objection to it—the possibility of producing slight dermatitis, and this can be guarded against by a layer of sublimate gauze directly over the wound.

CASE II.—This case is one of a comparatively common affection, many examples of which you see at the college, the dispensary, and the hospital clinics. The disease is cancer of the female breast. There are no special points of interest in the history: the woman is about forty years of age, married, and has no family history of malignant disease. I have alluded to this point on a previous occasion, and have told you that I am growing more and more skeptical as to any great influence of heredity in the production of this disease. The venerable Dr. Parker, of this city, came to the same conclusion, he has told me, after an analysis of over five hundred breast amputations. The trouble in this woman's breast began two years ago, as a small lump, which she disregarded until recently, when she has submitted to a number of applications, with the hope that it would be dispersed, and she would avoid an operation. The tumor is not adherent to the subjacent tissue, although the skin is glistened to it and the nipple is slightly retracted. I have been unable to feel any enlarged glands in the axilla, but that is not positive evidence that the glands and lymphatics are not affected. In all these operations I open the axilla, and, if I find any of the glands increased in size, as I proceed with the operation I remove them, together with all the loose areolar and fatty tissue of this space. The disease has been shown not to recur so soon, and often not at all, in cases where the axilla has been thoroughly scooped out. Küster, of Berlin, has recently presented one hundred and thirty-two cases of removal of the breast, in the majority of which the axilla was cleaned out, and he has found that this precaution postpones the time of recurrence. In fact, in twenty-one and a half per cent. of his cases life was prolonged beyond three years, a time which by some is considered equivalent to a cure. Sir James Paget, however, maintains that ten years are necessary for the test.

The tumor here presents all the signs of hard, or scirrhouss, cancer. A natural question on the part of the patient generally is, how much of the breast it will be necessary to remove; and she always wishes the excision to be as limited as possible. It is a safe plan always to reply that you can not determine exactly the extent of the disease until the time of the operation, but that you will not remove more tissue than is found necessary. However, it is always well to remove the entire gland. While the thorough removal of the glands of the axilla sometimes increases the mortality as much as nine to fifteen percent, according to different reporters, yet this fact is more than compensated for by the longer interval before the disease again manifests itself. In many instances a permanent cure has taken place. I have extirpated a portion of the pectoral muscle along with
the gland, and all the areolar contents of the axilla, exposing the vessels. Those above the clavicle are not enlarged; had they been, the operation would not have been performed, as that condition would show an uncontrollable extension of the disease. The skin, although considerable has been removed, is sufficiently lax to be approximated, and has been united over the gap by means of continued catgut sutures, and two decaleified-bone drainage-tubes have been inserted, one at each end of the wound. Over all has been placed a free supply of disinfectant absorbent dressing, in the form of sublimate-jute cushions. Although, in order to guard as much as possible against recurrence, the glands and lymphatics are radically removed, do not forget that a wide portion of skin must also be taken away, even if the wound can not be closed, for return is most frequent in the skin.

Case III.—The next case is that of a boy, fourteen years of age, who has necrosis involving the lower end of both tibiae. He gives a history of sickness dating from last winter. From the symptoms, as he describes them, it would seem that he suffered from pleurisy, which was, it is said, followed by acute articular rheumatism affecting the knee joints and eventually settling in the ankle joints. Subsequently matter was discharged from each ankle, and the boy now presents himself with several openings over the lower portion of the tibia in each leg, through which dead bone can be felt. I doubt very much whether the boy had rheumatism; it was more likely osteo-myelitis, or inflammation of the marrow of the bone, of infectious origin. The history of pleurisy and the fact that both tibiae are affected are suggestive of an infectious origin. We have lately had here, you will remember, a patient who received an injury of the skull, and osteo-myelitis of the head of the tibia, of infectious origin, resulted therefrom. This disease is apt to center at the epiphyses, and has been called by English writers epiphysitis. Occurring so near the joint, it is apt to invade the latter and disable it. You have seen several such cases already in this place, and last winter a patient was presented to the class on whom an operation was performed for removal of the dead bone, which barely fell short of the ankle joint, and he made a prompt and good recovery. It may not always be easy to determine whether a separated piece of necrosed bone is present in a given case, and, consequently, whether or not an operation is indicated; if, however, the disease has continued for six months, you may feel quite certain that, on opening the cavity, you will find dead and probably loose bone. All the diseased structure should be scraped out with sharp spoons, the cavity thoroughly cleansed, drainage established, and an antiseptic dressing applied. We have found here that there is a mere shell of healthy bone between the abscess-cavity and the ankle joint. Nevertheless, it is hoped that the disease will be arrested, and that after a time the usefulness of the ankle will be restored. The left tibia was more extensively diseased and larger than the right one, and on this side numerous pieces of greyish necrosed bone were found. On the other side, only spongy, altered, pus-sodden bone was encountered. The usual permanent antiseptic dressing was applied.

Correspondence.

LETTER FROM VIENNA.

The Winter Course.—A Scarcity of Anatomical Material.—
Abdominal Surgery and its Results in Europe and in America.—The Manners of Vienna Students.

VIENNA, November 10, 1883.

The winter semester is now just a month old, and the medical department of the university has never been in a more flourishing condition. The number of students is unusually large (at least twelve hundred), and several of the lecture-rooms are daily packed to their utmost capacity. So many are the first-year students that the supply of anatomical material has been
entirely inadequate, an unheard-of thing for Vienna. Even the
erity American, in spite of diligent endeavors and frequent
resort to the generally effective Guides, has been greatly re-
stricted in his efforts to freshen up his anatomy. And this
leads me to say, in passing, that dissecting privileges in Vienna
are not all that they have been represented to be. Aside from
the fact that the subjects are never injected with preservative
fluid, and hence will keep but a short time, there is a curious,
unscientific custom which prevails here, of lopping off a number
of limbs and dealing them out separately for dissection. Add
to this the difficulty and annoyance which a foreigner experi-
ences in trying to obtain fresh material, and the necessity of
renting a private room in which to work (for the Vienna medi-
cal student has very crude ideas regarding the rights of his col-
leagues), and it remains a matter of considerable doubt whether
it pays for a graduate to spend much of his time here in prac-
tical anatomy. He may gain in quantity, but with a propor-
tionate loss in quality.

Surgically, there has been nothing of especial interest during
the past month. Billroth and Albert hold clinics in general
surgery daily. This week an ovariotomy was done by each of
these gentlemen, in the public amphitheatre, but with proper
antisepsic precautions. Albert operates under spray, and in a
room in which the heat is unbearable. Billroth relies more
upon absolute cleanliness, irrigation with carbolic acid, and the
use of iodoform dressings. The mortality in both clinics is
surprisingly small.

There have been a number of interesting cases in the lying-
in wards since my last letter, including two of rupture of the
uterus. In one instance delivery was effected by craniotomy,
the child (weighing five thousand grammes) being entirely
within the uterine cavity. The second case was one of extreme
malacosteon, in which delivery without Cesarean section would
have been impossible. The woman had borne three children
at full term and three prematurely. She was eight months
pregnant, and had been in labor over twenty-four hours. When
brought to the hospital she was moribund. Examination
showed that the breech was presenting, while the rest of the
(macerated) fetus lay among the intestines. The contracted
uterus was felt below and in front of the child. Professor
Braun discussed the advisability of performing laparotomy, but
rejected this extreme measure on account of the low condition
of the patient. At the Section Cesareae legida, performed after
death, the condition was as stated in the diagnosis. Strange
to say, the rupture involved the entire cut-de-sac and posterior
wall of the vagina, the cervix being only slightly torn. Hamnor-
riage had not been excessive.

Braun has recently performed several laparotomies, the last
two being for the removal of uterine fibroids. The operations
were rapidly and easily accomplished, with but slight loss of
blood, though in both instances the uterus was entirely removed.
The modus operandi was briefly as follows: Having exposed
the tumor by a long incision, extending one or two inches above
the umbilicus, the mass was raised and its base quickly enucleated
with an cerasco-chain (the instrument generally used here is
a modified Chasaignac), which was tightened, and re-enforced
by a loop of rubber tubing. A bold incision was then made
into the capusle of the tumor, and the growth was neatly shelled
out, leaving nothing but the uterus behind. The organ itself
could now be removed at leisure, the hemorrhage being per-
fecfly controlled, and the stump trimmed down, cauterized, and
included in the lower angle of the abdominal wound. The
ceraseen was removed on the sixth or eighth day. The opera-
tions were performed in the crowded lecture-room, with no
 Efforts at antisepsis aside from perfect cleanliness. The wounds
were dressed with iodoform powder and carbolized gauze, no

The various courses continue to be well attended, and some
of the regular university lectures are frequented by Americans,
least by such as can breathe for an hour and a half in an
atmosphere as stifling as that of a police court. The German's
hated of oxygen is astonishing. He seems to drink in carbonic
oxide with plant-like avility, and blooms in the air of a lecture-
room where even the fabled western medical student would
quickly droop. But bad air is one of the least of the obstacles
with which the fastidious foreigner has to contend in Vienna,
for here bad manners flourish to a degree almost incredible.
The Vienna medical student is a polyglot, nondescript being.
He may be a Russian, Hungarian, German, barbarian—almost
anything except a gentleman. This idea, which at first exists
only in the form of a suspicion, becomes an assured fact to a
man after he has spent two or three months in daily jostlings
with the aforesaid. So discourteous is the unruly student at
times, so persistent is he in his determination to place his broad
back between any object of interest and the rest of the spec-
tators, that patience ceases to be a virtue, and he receives a
forbidding hint which even he can not disregard. But, consider-
ing the great number of nationalities represented here, the students'
relations are generally pretty harmonious.

Few American physicians study abroad without spending
some time in Vienna. Some stay only two or three months,
others, interested in special studies, may spend as many years,
but probably every one remains a little longer than he had int-
tended. There is something in the busy atmosphere of the
great hospital, the society of one's countrymen and fellow-
students, and, above all, in the abundance of opportunities, that
is very attractive to the fresh comer, and that it is hard for one
to leave behind. In some respects Vienna will probably never
be equaled as a center of medical study, yet, in all departments
except obstetrics, who can tell how much our own clinical
advantages may be extended in a few years, so that a foreign
trip may become a luxury rather than a necessity?
M A D I C A L P R A C T I C E A N D S T A T E B O A R D S O F H E A L T H.

At various times we have expressed doubt as to the wisdom of charging a board of health with the delicate and exacting duty of administering laws regulating the practice of medicine. It can hardly be maintained that there is any obvious or natural connection between such administration and the proper functions of a sanitary board, the investigation of the causes of disease and the supervision and enforcement of measures intended to abolish or restrain their action. We have never entertained a doubt that those boards which have been charged with the additional duty referred to have regarded it as an unwelcome and distracting burden, however earnestly and conscientiously they may have labored to discharge it.

Some of the States have seen fit to charge their boards of health with the function in question, with a view, it is to be presumed, of avoiding a multiplicity of boards, and perhaps with an eye to economy. These motives, it must be allowed, are in harmony with the principles which should guide legislative bodies in providing for carrying out the policy of the State; the questions will come in, however, whether simplicity and economy of this sort are not after all illusory, and whether what is best is not in the end also the cheapest. It must be added, nevertheless, that excellent work has been done by the two boards that have been most prominent in this way—that of Illinois and that of West Virginia. No matter how we may look at the subject, on general principles, no right-minded man will question the duty of facilitating, rather than obstructing or even criticising, except on good and substantial grounds, the actual regulation of medical practice by a health board of which such action is required by law. The statutes under which the boards act have been framed in the interest of the whole people, rather than in that of the profession. From a scientific point of view, of course, this is not all that we could desire; but it should be borne in mind that the spirit of our institutions does not admit of class legislation further than what may be requisite for the common good. It is true, these laws do not vest the profession of medicine with all the dignity we should like to see hedge it about; they do not set legitimate medicine up on a pedestal and create a guard of honor to surround it. The dignity of the medical profession is best guarded within its own ranks. Therefore we should not expect any law to accomplish for the profession anything more than, with reasonable legal protection against its own vitiation, it can accomplish for itself.

There is reason to think that some of our number carry their devotion to medical science so far as to expect the law to do something special for its advancement. This, of course, the law is incompetent to do, except in so far as such action may be required for the benefit of the people as a whole. It is desirable that this view of the matter should be spread among the profession, and we are glad, therefore, to see that some pains are taken now and then to contribute to that end. An instance of the sort is the immediate occasion of this article. We refer to a letter published in a recent issue of an Illinois newspaper.

A Q U A R R E L A M O N G S A N I T A R I A N S.

The untutored imagination may picture to itself that, of all men, the sanitarians ought to love one another. In fact, there has been little in general to indicate that such was not the case, notwithstanding the occasional conflicts that have broken out between various boards of health and other sanitary bodies, official and non-official. As a rule, much zeal has been displayed by individual members of these organizations, not only in the performance of duties strictly official, but also in seeking to increase their efficiency by attendance at conferences, conventions, and the like. On such occasions there may have been an under-current of jealousy and a suppressed purpose to thwart each others' pet projects, although to all outward appearance the genuine student of hygiene and the covert promoter of this or that engineering scheme have been in perfect accord.

Smooth as the surface has been, however, a deep-seated contention has at length broken out. A difference of opinion as to the comparative merits of various systems of sewerage has, we are sorry to say, led to such a state of things that the secretary of the State Board of Health of Maryland, Dr. Chancellor, has felt called upon to resent certain imputations which he attributes to Colonel Waring, of Newport, and Dr. Billings, of the army. We gather from Dr. Chancellor's article, published in a recent issue of the "Maryland Medical Journal," that an engineering journal has taunted him with being an "amateur," and that between the lines he reads "Colonel Waring and his system." Furthermore, he supposes that Dr. Billings lately went out of his way to urge a particular system of sewerage upon the attention of the Mayor of Baltimore, on the occasion of his having given a lecture on hygiene under the auspices of an influential literary institution of that city, at the same time intimating that a system favored by Dr. Chancellor was condemned by sanitary engineers both in this country and in Europe.

These, to be sure, are but side issues in Dr. Chancellor's article, which is the main is a very able defense of the Liehrm pneumatic system of sewerage now in operation in Amsterdam. They are the features, however, that will most attract attention. There seems to us to be no occasion for surprise that a man of Dr. Chancellor's position should show some warmth in resenting such imputations as those which he attributes to his fellow-sanitarians, but we still entertain the hope that they were not intended as reflections on his knowledge of the subject, but were rather the outgrowth of legitimate advocacy of firm convictions. It is quite possible for such convictions to lead to enthusiasm in behalf of particular methods, and even of special mechanical devices, without the slightest room for suspicion of
any prejudiced or interested bias. A sort of metonymy is apt to come into play when men suffer themselves to become thoroughly imbued with the importance of a principle, and, really striving for the principle, they seem to be intent on magnifying some particular one of its methods of application.

It is hardly to be supposed that all the apparent zeal in the pursuit of sanitation witnessed of late years has been genuine. In this sphere, as well as in so many others, doubtless the livery of the Court of Heaven has been stolen to serve the devil in. We can easily imagine the secret agent of somebody's patent trap masquerading at sanitary conventions as a hygienist. All these things may be taken for granted, and they may serve as a ready explanation of much of the minor wrangling that makes itself heard at times; but that men of such standing as Dr. Chancellor, Dr. Billings, and Colonel Waring are to be judged in the light of any such considerations, we are not ready to believe until further evidence is forthcoming. We feel confident, on the contrary, that it will be found that these three gentlemen have not in reality suffered the foundation to be laid of any breach in their concord of labor.

**MODIFIED SMALL-POX INOCULATION.**

During the late civil war, as many of our readers are doubtless aware, a medical officer of the Confederate army found himself face to face with an outbreak of small-pox, and without any supply of vaccine or the possibility of obtaining it. Under these circumstances the idea occurred to him that he might, so to speak, make it—and this was how he undertook to do it, and how, as he imagined, he did it: He mingled small-pox virus with cow's milk, apparently with the notion that the mechanical mixture of the contagion of small-pox with a product of the animal whose system was commonly credited with the power of converting the one disease into the other would answer every purpose. With this mixture of milk and variolous matter he inoculated his men, and the result was in every way satisfactory. Not only did he shield his force from a murderous spread of the unmitigated disease, but he also confirmed his theory—in his own estimation. As a consequence of the latter circumstance, the experiment has lately been brought into notice again, and its repetition has been suggested as a legitimate and trustworthy method of obtaining a good quality of vaccinal material for ordinary use. This is why the matter seems worthy of further notice than it met with at the time.

Let us look at the consequences that might follow a general resort to this practice. We must admit that the deduction drawn by the experimenter may have been erroneous. Over and over again, in the history of the old practice of variolation, inoculated small-pox proved so benign, for long periods together, that it did no more harm than ordinary vaccination generally does. That benignity, however, never proved to be a lasting feature—it was found that it could not be depended upon. But it took time to show that—a length of time that has never been devoted to testing the conclusions of our experimenter, or even those of Thiele, Ceely, and Badcock. The question now is, shall such a course of investigation be entered upon? Were any great practical benefit likely to be reached by it, it might be justifiable to look upon its possible dangers as proper to be encountered for the sake of the ultimate gain.

When we consider, however, that the benefit must be limited to the establishment of a means of obtaining vaccine under circumstances quite unusual, and that under such circumstances a resort to variation pure and simple is perfectly justifiable, the possibility of danger must be regarded as actual danger.

We have already said that the theory of the transmutability of small-pox into cow-pox by passing it through the cow's system, to say nothing of the superadded notion of reaching the same result by the crude expedient of a mere mechanical mixture of variolous virus with milk, has never been proved. Until it is shown beyond peradventure that variation of the cow gives rise to cow-pox, and nothing but cow-pox, we can be safe only by assuming that the resulting disease is small-pox, with all its infectiousness preserved, however mild its actual manifestations may be even in a long series of inoculations. We should feel bound to look at the matter in this way, even if nothing more than theoretical objections could be opposed to the transmutation doctrine; but, when we are enabled to add that an experimental investigation carried out in Lyons some years ago, by a commission of which so capable an experimenter as M. Chauveau was a member, resulted in satisfying the commission that the doctrine was utterly unfounded, and that a recent study of the whole question anew by a well-known English veterinarian has tended toward the same conclusion, we must say that the probability is vastly strengthened that he who inoculates with small-pox virus, "modified" or unmodified, really spreads small-pox and nothing else. With this conviction, we must urge the utmost caution as to experiments in "modified inoculation."

**MINOR PARAGRAPHS.**

**NEPHRECTOMY BY LAPAROTOMY.**

We learn from the London journals that Mr. Knowlesy Thornton lately performed nephrectomy at the Samaritan Hospital by the abdominal incision, and that he had recourse to a procedure which he considers important as a means of avoiding septic infection—stitching the vesical end of the divided ureter into the lower end of the wound. The case was that of a young woman with a history of seven years' renal trouble. The kidney was much enlarged and encapsulated, and contained a quantity of pus and putty-like material. Mr. Thornton is credited with having been the first to suggest this method of dealing with the ureter.

**MEDICAL TRAMPS IN BOSTON.**

At a recent meeting of a section of the Suffolk District Medical Society, of Boston, reported in the "Boston Medical and Surgical Journal," Dr. H. I. Bowditch warned his fellow-members against the wiles of a band of medical tramps at present infesting Boston and its suburbs. One of them, wearing an artificial leg, professes to be a graduate of Harvard and the son of a physician, and presents plausible testimonials. The latter have been found to be forgeries, and the man himself is a swindler. Another is a young man, elaborately dressed and of
a favorable appearance, who makes it a practice to call at a physician's house when the latter is not at home, representing himself as the son of a noted New York physician, an intimate friend of the doctor at whose door he finds himself, and stating that he has been robbed of all his money and wishes to borrow a small sum, from three to five dollars, to enable him to get home. Failing, in spite of a display of tears, to obtain the money from the person who answers the bell, he asks when the doctor will return, but is very careful not to come back at that time. Still another is a man of swarthy complexion, who pretends to be from India, but is probably an aunat cheat.

PHYSICIANS AND SANITATION.

Some weeks ago, in an article with this title, we deprecated what seemed to be the spirit in which the "Sanitary News," of Chicago, had commented on the undue importance sometimes attached by members of the medical profession to measures for the regulation of medical practice as a part of the duties of sanitary boards. We are, therefore, very glad to be able to say now, on the authority of the excellent journal in question, that its remarks were not intended to apply with the sweeping force that we supposed. The "News" handsomely expresses its admiration for physicians who are also sanitarians—a restriction to which, taking the word "sanitarian" in its full sense, the better part of the profession will certainly agree.

HIGH APARTMENT-HOUSES.

A certain sentimental satisfaction is to be drawn from the fact that the Committee on Hygiene of the Medical Society of the County of New York has recorded its conviction of the detrimental effect of the hagé and hideous apartment-houses that are springing up in such numbers. Unfortunately, neither the committee nor the society has any jurisdiction in the matter, and perhaps it is too much to expect that both the power and the inclination to abate these nuisances will be found to reside with any one of our city departments, but we must take the temper of the community if its disgust is not yet turned into some effective channel.

A NEW MEDICAL BIOGRAPHY.

The first part, eighty pages, of a somewhat pretentious dictionary of medical biography has just been published in Vienna and Leipzig. It is edited by Dr. Wernich and Dr. Hirsch, of Berlin. Some idea of the size of the work may be formed from the fact that the first Lieferung carries it no farther than the name Albers. Among the numerous contributors we notice but one American, Dr. Billings, of the army. In view of the well-known accuracy of Dr. Billings's literary work, we can hardly suppose that he actually wrote the few notices that appear of American physicians, for they are by no means carefully done. For example, Dr. D. Hayes Agnew is entered as "Agnew, Hayes A.," and the latest work credited to him is recorded as having appeared in 1868.

AN UNOCCUPIED CHAIR.

In the figurative language of the "Progrès médical," the chair of diseases of children of the Paris Faculty of Medicine has been "put to sleep," the faculty having allowed six months to elapse since the death of its late incumbent, M. Parrot, without formally declaring it vacant. It seems that no one has yet been found who is thought worthy to fill it. At one time a number of surgeons aspired to the chair, and there was some talk to the effect that an alternation of physicians and surgeons was not by any means an unwise arrangement. This gave rise to a good deal of opposition on the part of the physicians, however, and the faculty, which seems to have rather favored the idea at first, found itself compelled to yield. The prospect is now that the chair will remain unoccupied until some unknown candidate shows himself obviously the best man for the place, the functions devolving meantime upon several "agreis."
is to patrol the poorhouse grounds. In this asylum, also, the bathing is done in the coal cellar—six patients in the same water, which is then saved to wash the dirty clothes. The woman's wards here, however, show the good effect of cheerful industry on the insane. On the day of the secretary's visit all the women were sewing and knitting and interested in their work. But, as a general custom, the insane in county poorhouses are kept in attics and basements and out-buildings. They are filthy and squalid, they lounge about in idleness in shabby courtyards, and little effort is made to keep the sexes separate.

"In Chenung County cells still exist long used for insane quarters, and in one of them a man lay seventeen years unclothed, except for a ragged quilt, in a dry-goods box, on a bed of straw. Similar cells exist in the Niagara County poorhouse. In Tioga County the secretary found the insane shodless, bareheaded, compelled to sit on the floor, and both men and women patients under charge of a male pauper. The removal of such patients to Willard Asylum proves that they can be humanized and made and made.

"The association recommends that poorhouse insane wards and county asylums should be abolished, and all classes of insane cared for by the State in cottages of moderate cost on the vacant lands of the six present State institutions. The association also urges the opening of training schools for nurses in insane hospitals."

A NEW MEDICAL SOCIETY IN ORANGE, N. J.—A preliminary meeting for the formation of a new medical society in Orange was held on Friday evening, December 14th, at the house of Dr. William Pierson, and another meeting will be held January 3, 1884, at the house of Dr. George Bayles, when, it is expected, the organization will be completed. It is thought that the new society will be styled the Orange Mountain Medical Society. The membership will include gentlemen from Summit, Millburn, Montclair, Bloomfield, and Roseville.

THE SOCIETY OF MEDICAL JURISPRUDENCE AND STATE MEDICINE.—The following-named gentlemen have been elected officers for the ensuing year: President, Mr. William Barnes; Vice-President, Dr. E. J. Bermingham; Secretary, Dr. W. E. Brill; Corresponding Secretary, Dr. J. F. Chauveau; Treasurer, Dr. E. C. Harwood; Financial Secretary, Mr. M. F. Eller; Trustees, Dr. E. C. Spitzka, Dr. C. A. Leale, Dr. J. J. Henna, Dr. J. H. Fruitnight, Dr. A. M. Jacobus, Mr. S. B. Livingston, Mr. H. W. Sackett, Mr. E. H. Bann, and Mr. D. M. Shaw.

The Northwestern Medical and Surgical Society.—At the meeting held on Wednesday evening of this week, Dr. E. C. Harwood read an interesting and important paper on "The Relation of a Physician to the Commonwealth."

THE FRENCH ACADEMY OF MEDICINE has elected M. de Quartrefages a membre associé libre, subject to the approval of the President of the Republic.

The University of Berlin.—The "Medical Times and Gazette," states that the chair of comparative anatomy has been transferred from the medical to the philosophical department, being merged in the chair of zoology, to which Professor Schulze, of Gratz, has been appointed.

"The Surgical News" is the title of a new eight-page octavo quarterly journal published in Richmond by Dr. C. A. Bryce, who is also the editor. The first number, dated January, 1884, contains two original communications and a number of selections.

AMERICAN PORK.—One of the commissioners lately appointed to inquire into the matter of the alleged prevalence of trichinosis among American hogs is reported to have said, after an examination of hogs in some of the Western States, that he had found much less of the disease than he had expected to meet with.

OBITUARY NOTES.

Calvin Ellis, M. D., of Boston.—Dr. Ellis, the professor of clinical medicine, and until quite recently the dean of the faculty, in the Medical Department of Harvard University, died last Sunday, after a long illness, which he himself diagnosed as ulcer of the duodenum—correctly, as the post-mortem examination showed. The immediate cause of death was peritonitis, due to perforation. Dr. Ellis was born in Boston in 1826, and received his education wholly in that city, taking his medical degree from Harvard in 1849. He was a diligent student, a conscientious and painstaking practitioner, and a most effective clinical teacher.

Thomas S. Kirkbride, M. D., of Philadelphia.—Dr. Kirkbride, the distinguished alienist, died last Sunday, at the age of seventy-four years, at the Pennsylvania Hospital for the Insane, of which he had been the physician-in-chief for forty-three years. Dr. Kirkbride was a native of the State of Pennsylvania, and received his medical degree from the Medical Department of the University of Pennsylvania in 1822. For several years in succession he was the president of the Association of Medical Superintendents of American Institutions for the Insane, and he was so closely identified with the institution over which he presided that it was familiarly known among the profession as "Kirkbride's Asylum." His career was long, laborious, and in the highest degree honorable.

Professor Ercolani.—Professor G. B. Ercolani, one of the most distinguished of the modern scientific men of Italy, died at Bologna, November 16, 1883.

Count Giambattista Ercolani was born in Bologna, in 1819, of an ancient and noble family. He was the favorite pupil of the famous Antonio Azzopardini, and devoted himself early to comparative anatomy and pathology. The revolution which swept over Europe in 1849 found him in an earnest defender of the liberties of Italy, and, as a result, like Carl Schurz and Virchow, an exile. He sought refuge in Turin, and there was appointed professor, and afterward director of the veterinary school connected with the university. He remained there until 1865, when he returned to Bologna, where he accepted a similar position in the old university. By his energy and influence new buildings were erected, the school was reorganized and greatly enlarged, and a valuable pathological museum was established. He held the position of rector of the university for a number of years, and was permanent secretary of the Academy of Sciences of the Institute.

Like his friend Virchow, of Berlin, his reputation was not alone for scholastic and scientific attainments, but his early career as a defender of popular rights made him a favorite with the citizens, and he was three times elected to and served in the Roman Parliament.

His publications have been numerous, and are characterized by a careful scholarship and scientific accuracy truly exceptional. Most of his contributions appeared originally, with illustrations of the highest order, in the "Memoirs of the Academy of Bologna."

The work by which he is best known, and that promises immortality to his name, is the "Histology and Physiology of the Placenta of Mammals," in which he deduces a single law of anatomical and physiological modality of embryonic nutrition in all vertebrates. To his first publication upon this subject was awarded the prize of the French Academy. These publications were gathered into a completed treatise (a part of which was

written by the author expressly for the purpose), by Dr. Henry O. Marcy, of Boston, and published in two volumes, in London and Boston, in 1880.

Professor Erholan's researches upon the pathology of the placenta are of a value and importance scarcely second to any of the most brilliant demonstrations made in the entire field of pathological science. To the anatomist, the physiologist, and the biologist, as well as to the physician, the work of Erholan will ever stand as a monument to "science which is pure and simple truth."

Dr. Hilton Fagge, of London.—Charles Hilton Fagge, M. D., of London, the well-known physician of Guy’s Hospital, died on the 19th of November, of an aneurysm of the aorta. For several months past he had been aware of the existence of the disease, but, although he avoided the hardships of practice in consequence, he continued his professional work in other respects up to the last, and the final attack of syncope, supposed to have been owing to rupture of the aorta, followed close upon his active participation in a public examination. Dr. Fagge will be remembered as the author of many notable contributions to the literature of medicine, chiefly in the volumes of "Guy’s Hospital Reports," and of the "Transactions of the Pathological Society of London," and as a most successful student and teacher of medicine.

Letters to the Editor.

DR. POMEROY ON DISEASES OF THE EAR.

New York, December 17, 1883.

To the Editor of the New York Medical Journal:

Sir: In the "Cincinnati Lancet and Clinic" for December 8, 1883, p. 321, I notice a review of my book on "The Diagnosis and Treatment of Diseases of the Ear," in which my faunal Eustachian catheter is criticised somewhat unfavorably, although otherwise the book is very kindly noticed. I would beg to state that the author of the critique is in error in supposing that the danger of injecting the tympanum with this instrument is greater than when using the Eustachian catheter. For a moment, look at the facts: When the Eustachian catheter is properly introduced, its beak enters the faucal mouth of the Eustachian tube a little way, and, when fluids are injected, it is perfectly feasible to throw them into the tympanum, although this is not ordinarily intended, the object being to act only on the orifice of the tube, and perhaps a little way up toward the tympanum. With my faunal catheter the instrument is so placed in its introduction that the orifice of the instrument comes in contact with, or very near to, the orifice of the Eustachian tube, and does not in any event pass into it. With the best possible adjustment of this instrument, the fluid is thrown against the mouth of the tube and in the direction of its long axis.

It then obviously follows that the tympanum can not be injected by this means, except in a very fortunate and quite exceptional adjustment to the orifice of the tube. I mentioned the single case in the practice of Dr. Weir out of, perhaps, an excess of honesty, being careful not to be guilty of anything looking like special pleading.

With the immense number of times I have used this instrument in injecting fluids against the mouth of the Eustachian tube, I have never seen an oitis to result, nor have I heard of a case in the practice of another where this accident has happened, with the one exception above alluded to. I may justly infer that, practically, there is only the remotest possible chance of such an accident happening. In regard to the difficulty of using the instrument, I would state here that I had purposely presented all the objections to its use, among which was the comparative difficulty of properly introducing it. I am quite sure that I can make an application to the mouth of the Eustachian tube several times, while the Eustachian catheter is introduced a single time. Where the velum is quiescent there is absolutely no difficulty in its introduction. Where the velum falls spasmodically against the posterior wall of the pharynx, there is difficulty in passing any instrument into the upper pharyngeal space from the throat; but, shall we refuse to pass probang, brush, porte-carsteinque, spray instrument, etc., into this region because it is difficult? I use my faunal catheter as much to-day as I did years since. If I often make a general application to the upper pharyngeal space, it is because I think, with many others, that such an application is indicated, rather than the specific application to the mouths of the tubes. I make this explanation, feeling that the author of the review in question would, had he all the facts presented to his mind, side most heartily with my own view of the subject. Very sincerely yours,

Oren D. Pomeroy, M. D.

A POSSIBLE RESULT OF HOT VAGINAL INJECTIONS.

To the Editor of the New York Medical Journal:

Sir: If it is not too late, I should like to call attention to an article on the above subject, by Dr. Bradford, in your issue of October 13th.

The first thing that occurred to me, as I read the symptoms following the injections, was that they were more likely due to the use of carbolic acid than of mere hot water. I should wish to ask Dr. Bradford, Were there any other of the recognized symptoms of carbolism, greenish urine, etc.?

Yours faithfully,

Kenneth W. Millican.

Proceedings of Societies.

NEW YORK CLINICAL SOCIETY.

A regular meeting was held October 26, 1883, Dr. L. B. Bangs Chairman for the evening.

CARCINOMA OF THE LARYNX.—Dr. D. Bryson Delavan related the further history of a case which he had presented at one of the meetings held last spring, prior to the performance of tracheotomy. The patient was first seen in October, 1882, and tracheotomy was performed in February, for the relief of dysphonia, which had become extreme. The disease involved only one half of the larynx, and the question of extirpation came up at the operation, but was decided in the negative. The larynx was opened low down, and it was sought to establish adhesions, to prevent infiltration if subsequent extirpation should be deemed necessary. Very great relief was afforded by the operation, and the progress of the growth seemed to be arrested for a time. Since July, however, the patient had run down quite rapidly; he was still alive, and was able to swallow liquids slowly, although he was much enfeebled and very feeble. Dr. Delavan was convinced that the man had lived much longer and been more comfortable than if extirpation had been performed. He thought division of the isthmus of the thyroid, which was not done in this case, would facilitate subsequent extirpation, and he would do it in another case.
Dr. Beverley Robinson asked whether the intra-laryngeal appearance had been changed by the operation. He had noticed this in some cases.

Dr. Delavan said that the growth seemed arrested for the time, in consequence, he thought, of the parts having been put at rest.

Dr. George L. Peabody asked if the operation of extirpation was done as often now as formerly.

Dr. Delavan thought it was now generally regarded as useless in carcinoma, but as capable of succeeding in sarcoma. It had now been done in about sixty cases of all sorts.

The Chairman asked what results had been obtained with tracheotomy in laryngeal phthisis.

Dr. Robinson said that the laryngeal symptoms often improved very much, and in some cases even disappeared entirely, but without any apparent effect on the condition of the lungs as shown by physical signs.

Pernicious Remittent Fever (?).—Dr. Robinson related a case that had come under his observation at Charity Hospital, and read notes prepared by Dr. G. C. Neiss, of the house staff. A painter, thirty-three years old, was admitted October 15th. He had been a hard drinker for a number of years, but not of late, except that he had been on a spree about a week before. He came in, as he expressed it, for "chills and fever," which he had had about six weeks. He gave the history of regular paroxysms—chill, fever, and sweating—and was suffering with a chill at the time of his admission. This was stopped by a teaspoonful of chloroform. He was given a cathartic, and was ordered an iron mixture, also ten grains of cinchonidine night and morning. At 11 p.m., while walking to the bath-room, he fell, apparently from muscular weakness. His pulse was then found to be incommensurable, there was a little rise of temperature, but no chill, and he was rational. On the 17th he was delirious, vomited a greenish fluid, and complained of pain in the head, which, however, did not seem to be severe. His expression was anxious and distressed, his pupils were slightly irregular and moderately contracted, his pulse was 140, and his respiration 34. In the afternoon he was semi-comatose. The liver was found rather small, and the spleen somewhat enlarged. A movement from the bowels was said by the orderly to have been bloody. Pulse 140, full; temperature 105° on; respiration 38. Ordered, at 3.30 p.m., a sponge-bath and ten grains of quinine, to be repeated at 5 and 7 p.m. At five o'clock the pupils were moderately contracted, and responded but little to light; the respiration was sighing, with a full breath at times, resembling the Cheyne-Stokes respiration; pulse 134; respiration 34; temperature 105.6°. At seven o'clock the patient was in a profuse perspiration. On passing a catheter, the bladder was found empty, but the bed was wet. Pulse 132; respiration 52; temperature 104.25°. Ordered: two drops of creton oil, to be followed by ten grains of iodide of potassium, and two fluidrachms, each, of spiritus Minidereri, infusion of tricitum repent, and infusion of digitalis, every two hours and a half; also, ten grains of quinine and a tablespoonful of whiskey every two hours; in addition, to have two sponge-baths during the night. The patient died the next morning without there having been any special change in the symptoms.

Post-mortem Examination at 3.30 P.M.—Rigor mortis pretty well marked. Lungs somewhat reddened, particularly at the lower part, and emphysematous. Heart somewhat enlarged, soft, and flabby; mitral valve a little enlarged. Liver, weighing four pounds, anaemic and of a dark-brown color, with pigmentation. Spleen twice as large as normal, gelatinous in consistency, and very dark in color. Kidneys: capsules somewhat adherent; light in color; anaemic; cortical striations lost in places. Intestines normal. Brain edematous.

Dr. F. Ferguson had made a microscopic examination of the heart and kidneys, and had reported: "The muscular fiber of the heart contains much fat. There are pigment granules in the kidneys, seen in section and in teased preparations, which is characteristic of the pigmentation found in pernicious remittent fever."

Dr. Robinson remarked that he had seen the patient only shortly before his death, and that at that time there seemed to be signs of congestion of many of the internal organs. Three different diagnoses had suggested themselves to him: 1. Pernicious remittent or intermittent fever. 2. Uremia, with congestions due to malaria. 3. Cerebral hemorrhage, possibly into the pons, and small. From the autopsy, he thought it pretty clearly established that the case was one of pernicious fever.

Dr. Peabody had made autopsies in two such cases, and had found marked pigmentation in the brain, liver, kidney, and spleen. The pigment was free in the vessels, and was not always found in the cells of the organs. It was very plain to the naked-eye examination. In the gray matter of the brain the vessels looked as if they had been injected. He thought pigment was found uniformly in the liver, but not so constantly in the brain. It was not usually found in the blood unless the patient had died during a paroxysm of fever. During life it might be absent in blood taken from the finger-ple; it was more likely to be found in that taken from the back, where the circulation was more sluggish.

Dr. A. A. Smith asked whether pigment found in small quantity would necessarily show malarial poisoning.

Dr. Peabody said he would like to add one more possibility to the three mentioned by Dr. Robinson, namely: diabetic coma. The urine had not been examined for sugar.

Dr. J. H. Emerson raised the question whether pigment was not found in cases of malarial poisoning that could not be called pernicious.

Dr. Peabody thought it was occasionally.

Dr. Smith thought it was frequently.

Fractures of the Lower Jaw.—Dr. Robert Abbe reported three cases of fracture of the lower jaw now under his care, illustrating points of interest in treatment.

The first case was that of a man, thirty years of age, who was struck by a broken cog-wheel, which made a considerable external wound, and fractured the lower jaw between the left canine and bicuspids teeth. A simple silver wire held the teeth together so well that no other appliance was needed to procure perfect union in good position. The result could not have been better.

In the second case, that of a large man of forty-five years, who was struck a violent blow on the right side of the jaw, at its angle, a vertical fracture occurred between the left median and lateral incisors. It was found impossible to retain the fractured surfaces in apposition with silver wire or with external dressings, although the man had a good set of teeth. The case exemplified a trouble Dr. Abbe had often found in such fractures, and he obtained the aid of his friend, Dr. Gunning, whose interdental splints, as well as his distinguished services in the case of the late Secretary Seward, had given him a wide reputation. Dr. Gunning applied a vulcanite cap, nicely adjusted to the crowns of all the lower teeth, back to the last molars, which, by its accurate molding (being modeled on a plaster cast of the
teeth taken from a wax impression), held the parts admirably without any fastening to the teeth, or any external dressing. This splint was undoubtedly the most accurate and beautiful of all surgical appliances for fracture of the jaw. Dr. Abbe here showed several double interdental splints, as well as the splint that had been used in the case of Mr. Seward. With the single splint, the patient masticated and ate comfortably; with the double one, an opening in the vulcanite was left in front for eating purposes, large enough to admit two fingers side by side, the upper and lower splint being united at the sides into one solid piece.

The third case reported had been seen ten days before. The man had been kicked on the head one year before, lacerating the cheek and fracturing the lower jaw between the left first and second molars. He was treated in a Boston hospital. Small pieces of bone had come away from time to time through a large fistula, which still remained at the site of the fracture. Union had failed to follow, and a most palpable cause was discovered in the intrusion of the greater part of the second molar tooth into the space between the fragments. It was found adhering, by its smaller fang in the gum, on the edge of the back fragment. It was readily removed, and already, in ten days, considerable solidity had ensued in the false joint. Such a case of non-union was mentioned by some authors as very infrequent.

I. Emmett Holt, M. D., Secretary.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A stated meeting was held November 24, 1888, Dr. B. W. McClellan, Chairman for the evening.

FATTY TUMOR OF THE FOREHEAD, WITH APPARENT FLUCTUATION.—Dr. A. C. Post presented a small tumor which he had removed from the frontal region, in a man, where it had been growing for two years past. It presented distinct signs of fluctuation, and, before its removal, was supposed to be a hygroma. It proved, however, to be a soft fatty tumor. Dr. Post believed it impossible to distinguish by the sense of touch the fluctuation of a sac containing fluid from the apparent fluctuation of a solid.

KAIRINE.—Dr. A. B. Ball made some remarks with regard to certain experiments with kairine in the reduction of fever, which he was not yet prepared to have published.

In the discussion which followed, the Chairman expressed the opinion that physicians often did more harm than good in administering remedies to control special symptoms of disease. In scarlet and other fevers, quinine, for example, had been given to reduce the temperature, and it not infrequently did more harm by its depressing effects than good by its influence upon the temperature.

TYPHOID AND REMITTENT FEVERS.—Dr. Ball remarked that most of the cases sent to St. Luke's Hospital with a diagnosis of remittent fever turned out to be cases of true typhoid fever. He did not believe that remittent fever was so common in New York as it had been represented to be. He asked Dr. Francis Delahfield whether cases of the disease appeared at Bellevue Hospital.

Dr. Delahfield replied that there was a fair number of cases of remittent fever at Bellevue Hospital, coming from the city and the neighborhood. He knew not what else to call the affection; there was continuous fever with moderate remission in the morning, the fever being affected by quinine, not merely transitorily, but permanently, and breaking up sometimes into remittent fever.

Dr. T. F. Cock said that many parts of the city of New York, before having undergone improvements, were strongly malarious, while at present the same regions were free from malarial affections.

Dr. Ball mentioned an instance which went to show that under special conditions malaria might develop in places usually free from it. At a certain improved part of the city the ground was dug up on the lot near a family who had occupied the house for years without a symptom of malarial disease. Shortly after these improvements had been begun two of the members of the family, who had not been from home in the mean time, developed typical ague. He believed, however, that the medical mind had been taken up too much with the idea that everything febrile in New York was malarial.

The Chairman said that he was informed by a gentleman, who was in Spain during the war of 1811, that in some of the most malarious districts the soil was dry and sandy, and the atmosphere wanting in moisture.

NEW YORK SURGICAL SOCIETY.

A stated meeting was held November 27, 1888, the President, Dr. Robert F. Weir, in the chair.

THE TREATMENT OF IRREDUCIBLE HERNIA BY OPERATION.—Dr. William T. Bell read a paper on this subject. [See page 680.]

Dr. Charles K. Brincon said that several years ago, during his term of service in the New York Dispensary, a colored child was brought there, eleven or twelve years of age, with an inguinal hernia on the right side as large as the child's head. It was irreducible, and had been so for a long time; perhaps had existed from birth. Only a portion of the contents of the sac could be reduced, and, when so reduced, there remained a band apparently passing from the upper portion of the sac to its fundus, which was supposed, both by himself and by Dr. Gordon Buck, to be a long band of adhesion. Dr. Bridgton operated, exposed the sac, and found that it was a hernia of the cecum. There was no meso-cecum. The cecum had simply slipped down behind the utricle vaginalis, and into that sac a portion of the small intestine had descended, which could be reduced, but the irreducible portion was composed of cecum. That portion which was thought to be a band of adhesion was the verumoin appendix. With considerable difficulty this was dissected free, the entire contents of the hernial sac were reduced into the abdominal cavity, and a pad was applied. On the following day the hernia was in the same position as before the operation, having been rendered so by a fit of coughing. There was so much tenderness that he hesitated about reducing it, and allowed it to remain. An abscess formed in the seromum which gave discharge to a small quantity of the fluid portion of the fecal matter, but nothing solid, and it continued to discharge for years afterward. The child was not at all benefited by the operation.
He had performed the operation referred to by Dr. Bull, that of tying the neck of the sac, and always resorted to it in strangulated hernia, but had his doubts as to whether it had been of service. In the cases in which he had tied it high up there had always been a necessity for the use of a truss afterward. He had also several times tried to approximate the columns forming the external ring, but without any benefit. On one occasion he excised the sac, but should never make that attempt again. It was a serious operation in a case of irreducible inguinal hernia, which was followed by a great amount of constitutional and local reaction. He thought the operation proposed by Dr. Bull, that of tying the sac and leaving the rest open to heal by granulation, was the best method to be adopted.

The President said he had an unfortunate experience in this direction about eighteen months ago. He attempted to perform this operation in a large irreducible inguinal hernia, as large as a child's head, which had so inconvenienced the man that he was incapacitated for any work. After the tissues had been divided and the sac opened it was found that the hernia consisted mainly of intestine, which was reduced and the sac divided, drawn together, and also the edges of the abdominal opening approximated, so as to only permit the exit of the spermatic cord, and antiseptic dressing applied. About forty-eight hours afterward symptoms supposed to be due to peritonitis developed, and the man in a short time thereafter died. The autopsy showed that the columns of the ring had been so approximated that a small portion of intestine had been forced down and nipped so as to cause intense strangulation and death of the gut. Dr. Weyr, therefore, thought the point well taken that in similar cases the edges of the abdominal opening should not be approximated, and also that the sac should be divided or tied high up.

**Un克莱e Fracture of Left Thigh a Hand's Breath Above the Patella; Resection; Fragments Cut by Wire Sutures.**—Dr. A. C. Post presented a specimen, and said: "On the 2d of July, 1883, I was on a visit to Charlotte, N. C., and saw a man, fifty-one years of age, who had been injured by the explosion of a boiler on the 24th of June, 1882. He had a compound fracture of the left thigh a hand's breath above the patella; also a compound fracture of the left arm near its middle, and sandys contusions of different parts of his body. He had recovered from all his other injuries, but the fracture of the thigh remained ununited. His general health was good.

"**Condition July 2, 1883.**—The limb is shortened about five centimetres. The upper fragment overlaps the lower on the outer side, and there is very free motion between the fragments.

"**Operation July 2d.**—The patient being etherized, I made a free incision over the anterior and outer surface of the upper fragment, divided the periosteum, and worked carefully on the surface of the bone with a blunt instrument, and, after a long and persevering effort, succeeded in turning out the end of the bone and removing it with a saw. The portion removed was a little more than three centimetres in length. The lower fragment was very deep and difficult of access, but I succeeded at last in exposing it sufficiently to pass a chain saw around it, and to remove its extremity, which terminated in a rounded point. The portion removed was a little less than three centimetres in length. It required much effort to bring the saw surfaces of the fragments into contact. I drilled two holes in each segment, and wired the segments together with annealed iron wire. A plaster-of-Paris splint, previously prepared, was applied to the dorsal and lateral surfaces of the limb. Carbolized compresses were placed between the lips of the wound, which were simply drawn toward each other, and secured by a roller bandage. Over this a plaster-of-Paris bandage was applied.

"**July 3d.**—The patient had been somewhat restless and uncomfortable during the night, but I found him in a very fair condition. Pulse 84, and of good volume. Tongue clean. I did not disturb the wound.

"**5th.**—Pulse 108, temperature 101°.5. Dressed the wound. Made a large fenestra in the plaster bandage. Removed the compresses. Washed the wound with carbolic acid, 1 to 40. Dustted the surface with iodiform. Applied lint wet with the carbolized lotion to the surface of the wound, which was in a good condition. Interposed, between the skin and the edges of the fenestra, lint moistened with carbolized oil two or three times to one ounce.

"**5th.**—Condition improved. Pulse 96, temperature 100°.5. Wound in good condition. Very little discharge. No odor. Dressed as before.

"**6th.**—Still improving. Pulse 102, temperature 99°.5. Same dressing.

"**7th.**—Pulse 95, temperature 100°. All symptoms continue favorable.

"A few days after the last report I came on to the North, and I have not seen the patient since that time. Last month I received a letter from his physician, Dr. J. P. McCombs, of Charlotte, giving me an account of the further progress of the ease. This letter is dated October 16th. He writes: 'The bone has united, and the wound is almost healed. He can not bend his knee much, but it is improving. He is walking on crutches. The limb is shortened about three inches. There is a large calculus all around the limb. He is very grateful for his prospects of a good leg.'"

**Adeno-Osteo-chondroma of the Submaxillary Gland.** Dr. F. Lane presented portions of a tumor removed from the neck of a man, twenty-three years of age, which had developed within about five years to the size of a hen's egg. In histological composition it was adeno-chondroma, with formation of true bone in small places. The operation was performed about three months ago, presented no difficulty, and will probably not be followed by recurrence of the disease, the tumor belonging to a rather benign species.

**Acute Pyelium of Urethral Origin.** The President presented kidneys and heart, illustrating acute pyelium of urethral origin. They were removed from the body of an apparently healthy man, twenty-five years of age, who had been subject to gravelly discharges traceable to stricture. He had had instruments passed from time to time during the summer and in the autumn. Last Sunday his attending physician introduced a sound, No. 25 French, which passed into the bladder without violence, and with no more difficulty than had been produced on all the other occasions. A few drops of blood escaped. On Monday the man was seized with a severe chill. When Dr. Weir saw the patient he had a temperature of 103° F., and he supposed it to be due to malaria, as he had known that the patient had suffered formerly from such chills, which had invariably yielded to quinine. The temperature, however, remained high, and within forty-eight hours afterward he began to develop joint pains and effusions. He complained of no distress in the bladder, but said that once or twice he had noticed that the urine was very slightly tinged with blood. The man became so delirious that he was removed to the hospital, where he died twenty-four hours afterward. Before death, evidence of periarteritis and endocarditis was detected, and the opinion was formed that it was pyelium. At the autopsy, multiple incursions, with grayish centers, were found in the cortex of the left kidney, the right being comparatively unaffected. Pericarditis
and recent valvar disease, with excava-tion at base of one of the cusps (ulcerative endocarditis), were found, and infarctions in the center of the substance of the heart. The rapidity of the course of the case was especially interesting. Dr. Weir had not seen in acute pyeemia heart lesions so distinctly marked as in the present instance. There were no lacerations of the aorta, but evidences of eromons cystitis were present.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

A STATED MEETING was held December 6, 1883, the President, R. A. Cleeman, M.D., in the chair.

Cysts of the Parovarium.—Dr. William Goodell showed two specimens, and remarked that both patients had recovered—indeed, he had never lost a patient from whom he had removed a parovarian cyst. In both cases a correct diagnosis had been made before the operation. An interesting diagnostic point was the complete absence of the fisces ovaricae. The color of the checks was good, and the countenance was free from the anxious expression present in cases of ovarian tumor. One tumor had existed for ten years, the other for a year. Another important point in the differential diagnosis was, not only the fluidity of the tumor, but its variable degrees of fluidity. On inspection, it was seen to reach to the sternum, and seemed to occupy a large portion of the abdominal cavity, but, when the hands were placed upon its sternal edge, it could be compressed to the level of the umbilicus. An ovarian cyst, on the contrary, was hard and incompressible. Exceptions to this rule were very rare—either a tense parovarian cyst or a fluid ovarian one. A third important distinguishing point was the long time—ten years in one of the cases—that the tumor had existed, and, furthermore, without marked deterioration of the health. After being tapped, these tumors usually filled again, but occasionally they did not, and a cure was brought about. In every case the fluid withdrawn had been liquid and generally colorless, but sometimes, in his experience, it had an emerald tint. These tumors were generally free from serious adhesions; but, if, in an operation for removing one, adhesions were found of which the foreible separation was for any reason unadvisable, or the cyst were intra-iliac-tentous, he would not hesitate to leave the adherent portion of the cyst-wall, or the whole cyst itself, after making a big hole in it, as the fluid it contained was bland and not irritating to the peritoneum.

Any one examining one of these cysts for the first time would consider it to be of ovarian origin, for it was only by patient research that the ovary could be found spread out over the cyst-wall. But the microscope would decide in any doublet case. The tumor was covered with a beautiful network of veins. When a cyst of the parovarium existed on one side, the ovary of the other side was usually found diseased, and should be removed. In these cases the remaining ovary was seen to be enlarged, and the site of a small ruptured cyst was pointed out. The Fallopian tube was enlarged, and its terminal vesicle, the hydatid of Morgagni, was likewise enlarged and cystic. This hydatid sometimes attained the size of an orange, and often ruptured spontaneously without any bad effects. A few years ago one of these small cysts ruptured while he was making an examination of the patient to ascertain its character.

Vaginal Hysterectomy.—Dr. Goodell also showed a cancerous uterus that had been removed per vaginum. In view of the very fatal results of hysterecetomy for cancer, he had been very unwilling to operate. In most of the cases that he had seen early enough for the operation to offer a chance of success, the patients had been unwilling to take the risk. On one occasion, when every preparation had been made to operate, the patient had a convulsion, and an examination of the urine showed a high proportion of albumin, in consequence of which he declined to operate. About a month ago Dr. Charles W. Dullea had called him in consultation to see a patient in whom the carcinomatous condition was limited to the anterior lip, and the uterus was movable. The case having been frankly put before the patient, and all the dangers pointed out, she decided to take the risk of the radical operation. The procedure proved not to be so difficult as he had anticipated. The first step was to scrape away all cancerous tissue, and to rear the remaining surface with Paquelin's cautery. The vagina was then thoroughly cleansed. A stout thread was passed through the cervix to draw the womb down, instead of using a volutina, the handles of which would have been in the way. A circular incision was made around the cervix, and the tissues were stripped up anteriorly and posteriorly to the reflection of the peri- toneum, and laterally to the insertion of the broad ligaments. Finally, the peritoneum was opened, and the womb was retroverted down into the vagina by means of an obstetric crotchet passed over its fundus. A strong thread was now passed through the body of the uterus, by means of which to manipulate it more easily. The right broad ligament was then ligated en masse, and a second (double) ligature was passed through it and tied on the opposite sides. This broad ligament was then divided, the uterus was drawn down, and the ligament of the left side was secured and divided in the same manner. The vaginal wound was closed and dressed with iodiform and cotton. A frank peritoneal nictis set in on the third day, and proved fatal on the fourth. The result had made him doubt whether the operation was ever justifiable; indeed, he felt disposed to avoid it whenever possible.

Dr. E. E. Montgomery inquired as to the feasibility of using the galvanic-wire écraseur to divide the broad ligaments, keeping the wire at a low red heat and dividing the tissues slowly, thus avoiding the necessity of a drainage-tube. Another method which he had been revolving in his mind was, to dissect the uterus out with a galvanic knife, leaving the peritoneum intact, thus to a certain extent imitating Dr. Marion Sims's operation of scraping and the use of chloride of zinc.

Dr. Goodell thought that the galvamic wire would get too hot as the loop grew small, and would then divide rapidly like a knife, involving the danger of secondary hemorrhage. He feared, too, that the steam generated by the hot wire would penetrate the peritoneal cavity and have an irritating effect. He had a cautery battery, but he had not used it since the introduction of Paquelin's benzoline cautery, as he found the latter far more handy and manageable. He thought Dr. Montgomery's suggestion of shaving out the uterus a very good one.

Ovariectomy.—By the courtesy of Dr. W. W. Warner, Dr. Montgomery showed the ovarie appendages which had been removed from a young lady for the relief of dysmenorrhea that had resulted in physical and mental failure. Menstruation had begun at the age of fourteen years, had always been painful, and had given rise to hysterical manifestations. Bathing at the seaside had at one time stopped the periods for three months; after this her health failed, her mind had been seriously affected for the last three years, and she would run away or do herself some violence at the menstrual periods if not closely watched. Examination showed the uterus enlarged and tender, and there was profuse leucorrhoea. The os uteri was dilated, the uterine cavity was scraped and cauterized with carbolic acid, and bromides, etc., were used internally, but no improvement resulted. The ovaries were removed, the day of the meeting, by abdominal section, catgut ligatures being used. The organs were very much enlarged, and contained small cysts. The abdominal wound was closed with silk sutures and covered with an impervious dressing of collodion, cotton, etc.
Hystero-epilepsy as a Complication of Pregnancy.—Dr. William H. Shipps, of Bordentown, N. J., sent the following communication:

"Briefly defined, hystero-epilepsy is a term applied to an abnormal neurotic condition in which are manifested certain phenomena characteristic both of hysteria and of epilepsy. Out of 276 patients confined at La Salpêtrière, Paris, under treatment for various nervous affections, 32 were diagnosed by Beau, a careful observer, as suffering from this disease. Among this number the malady assumed either a distinct or a combined form; hence he very wisely groups the cases into two classes. In the first, the hysterical seizures and epileptic fits remain distinct one from the other; to this form he adapts the term given by Landouzy, and designates it as hystero-epilepsy with distinct crises.

"In the second class, and the one of which this article furnishes an illustration, the hysterical and epileptic seizures are coeval, both developing at the same time; to this form the name of hystero-epilepsy with combined crises has been given. The object of this paper is not to enter into a consideration of the disease as it is met with in general practice, but simply to examine it as a complication of pregnancy, a standpoint from which, fortunately, we are rarely called to view it.

"During the early part of March, 1883, I was called to attend a woman said to be in a fit. Arriving at the house, I found, lying on a bed, a young woman, apparently seventeen or eighteen years of age, of fairly vigorous physique, who was struggling against the united efforts of two or three neighbors who sought to prevent her doing herself bodily harm in the violence of her struggles. Examination showed entire loss of consciousness; her eyes were open and staring, the pupils were widely dilated, she was frothing at the mouth, which was then tightly closed, and her pulse was full and bounding. It was ascertained that during the day she had been visiting a friend, herself the subject of some spasmodic affection, and, while in her company, became greatly exercised over some trivial occurrence, and in this state of excitement returned home, where she no sooner arrived than she was seized with a convolution. Her husband informed me that she was in the third month of pregnancy, and that prior to this morning she had on one or two occasions had attacks somewhat similar, though of less severity. I at once injected one third of a grain of morphia hypodermically, which in a short time was followed by a total disappearance of all spasmodic action, a state of stupor supervening, from which in the course of three or four hours she emerged apparently as well as ever. On the day following I was called to see her, and found her in a state of high nervous excitement, sobbing and deploving the presence of some impending danger which she, in her imagination, insisted was threatening her. In a short time the stage of muscular contraction, loss of consciousness, stupor, etc., took the place of the hysterical symptoms, finally terminating, as before, in a return to her normal condition.

"Without attempting to follow the case step by step, taking in all its details, and noting the many and peculiar phases through which it passed, it is interesting to note that prior to September 23, 1883, covering a period of two hundred days, not a day passed without the occurrence of one or more paroxysms. At times the hysterical phenomena would be most marked, and usher in the attack; then, again, the epileptic fit would take the precedence, always, however, accompanied by the undeniable imprints of the dual disease, hystero-epilepsy. In the interparoxysmal period she enjoyed, for the most part, average good health.

"On the morning of September 23d I was asked to see her in an attack of more than usual severity. When I reached the house she was profoundly unconscious, and had been so for several hours. The time for her approaching labor being near, I made a vaginal examination, but found no evidence of commencing uterine action. I ordered a hot mustard bath, mustard to the extremities, and bronchiates the moment she should be able to swallow. In the evening, when I again called, her condition was apparently unchanged. I then ordered a blister to the nape of the neck, and left the patient, to return early in the morning. At 7 A.M. a messenger called, saying that the woman was now perfectly rational, and, to all appearance, in labor. I at once responded, and found that she was having bearing-down pains of moderate intensity at intervals of five or ten minutes, the mouth of the womb dilating, and the vertex presenting. I remained by the woman’s side until 8.45 P.M., when the child, a healthy female weighing nine or ten pounds, was born. The labor did not differ from ordinary labors, except that it was only by the utmost vigilance that the woman was prevented falling into one of her acetunent attacks. After the birth of the child I gave it to the mother, at the same time remarking to her that, as she valued the life of the child, under no circumstances should she allow herself to have another convolution. She promised faithful obedience, and up to the present time has shown the slightest indication of her old trouble. It should be mentioned that, during the entire period the patient was under observation, she had daily taken large doses of the bromides and other nervines, without any effect, save perhaps in ameliorating the number and violence of the paroxysms.

"The case is interesting on account of the rarity of the disease as a complication of pregnancy, its persistence throughout the entire period, its resistance to all remedial measures, and the final disappearance of all symptoms after the termination of labor. Two queries very naturally present themselves: What was the exciting cause of the attacks? Would the induction of premature labor be justifiable in such cases? In answer to the first query, I attribute the attacks to a condition upon the brain and spinal cord, reflex in its nature, and developed or excited by the factors in utero. The happy termination of the case would seemingly offer a negative to the second query; but better judgment will, I think, suggest the wisdom of the operation and the danger of refusing to employ what, theoretically at least, offers the only chance of relief. At all events, in a similar case I would most certainly have recourse to the operation, and should expect from it the best results."

Reports on the Progress of Medicine.

Surgery.

By Charles S. Kelsey, M. D.

The Action of Heat on the Contagium of Septicaemia.—Dr. Dowdeswell ("Proc. of the Royal Soc," No. 221, 1883) has been making a study of the action of heat upon the contagium in the two forms of septicaemia known, respectively, as Da- vaine’s and Pasteur’s. Professor Rosenberger has recently published the results of his experiments in the same direction, by which he professes to have effectually sterilized by heat the blood and exudation fluids of the rabbit; and states that these fluids, so sterilized, upon injection into other animals, were found to be infective, reproducing the disease with the recurrence of the specific organisms which characterize it; he therefore regards these organisms as having no causal connection with the affections in which they are found, but as merely secondary or epiphenomenal. This would be the necessary deduction were it proved that the fluids had been effectually sterilized, and it was to test this point that Dr. Dowdeswell’s experiments were made with the co-operation of Burdon Sanderson. The results arrived at are exactly opposed to those reached by Dr. Rosenberger; and, from the experiments, the author concludes that the active virus of infection, both in the case of Pasteur’s septicaemia—the malignant sarcoma of Koche—in guinea-pigs, and in Davaine’s septicaemia in rabbits, is destroyed by the prolonged action of a sufficiently high temperature; that blood or exudation fluid so treated is not infective, nor in any appreciable man-
ney toxical, when injected in moderate quantities (up to 1 cub. centim.) into other healthy animals, while the same fluids unheated are invariably and fatally infective in infinitely smaller quantities.

In Davaine's septicaemia in the rabbit the author has found throughout his experiments that the period of incubation is remarkably constant, death, after the first generation of infection by putrid blood, almost invariably occurring in from twenty to twenty-four hours, and, consequently, that if it does not occur within about that period, it may be concluded that infection has failed: the animal may die subsequently, as rabbits in confinement constantly do, more especially under the conditions in which they are kept in laboratories; but, unless within about the period specified, they do not die infected with specific septicaemia, the characteristic organisms are not found in the blood, nor is that blood infective; hence it is not necessary to observe such animals for more than a few days after inoculation.

Displacement of the Heart by Violence.—The following case, by Mr. W. H. T. Winter ("Dublin Jour. of Med. Science," May, 1883), is a surgical curiosity, the author having been able to find but one similar—that by Dr. Stokes in the thirty-sixth volume of the "Edinburgh Medical and Surgical Journal." The patient, a lad, aged nineteen, was injured by the fall of a wall. The sternal end of the left clavicle was displaced upward, forward, and inward. The third, fourth, and fifth left ribs were separated from their cartilages, and on the front of the chest their extremities formed prominences. The heart was displaced downward and to the left, and there was a diffused impulse in the fifth and sixth intercostal spaces external to the nipple. The action of the heart was tumultuous, there was dyspnoea and the expression was anxious, the countenance was of leaden hue, the extremities cold, and the urine contained a trace of albumin.

Under general treatment the heart became after a time reconciled in a measure to its changed position, and the patient was comfortable unless he exerted himself. Six months after the accident the heart was still displaced, and exertion caused palpitation and dyspnoea.

In the similar case by Dr. Stokes the dislocation also remained permanent. In one case by Tibbitts ("Lancet," 1876, vol. i, p. 598) the heart suddenly replaced itself.

The Operation for Harelip.—Mr. H. G. Rawdon ("Brit. Med. Jour.," Oct. 13, 1883) lays a good deal of stress upon the following considerations: The first is as to the advisability of operating early—that is, within a few days of birth. His own experience has been entirely in favor of so operating, and has amply confirmed the validity of the main reason adduced for so doing—viz., that new-born infants are, for the most part, healthy and well nourished, and far better able to bear an operation within twenty-four hours of birth than possibly they may be for weeks or months afterward. These children deteriorate rapidly after the third week from improper feeding and mismanagement, and, unless the mothers obtain proper instruction as to feeding before it is too late, death is inevitable. The health and vigor of the child are of more consideration to the surgeon in determining whether to operate or not than the actual age.

As affecting this question of early operation the cases may be divided into two classes: those in which, with proper management, operation gives the capacity to suck as soon as the sutures are removed, which may generally be done on the sixth or seventh day. This class includes cases complicated with incomplete cleft palate; that is to say, cases in which the fissure is limited to the alveolar portion of the bone. Secondly, those in which, owing to the co-existence of complete cleft palate, the power of suction can not be given. In the first class the duty is to operate early, and in the latter also the surgeon is justified in operating immediately after birth. The alveolar cleft closes more symmetrically, quickly, and thoroughly, the difficulty of feeding is manifestly lessened, and the disposition to catarrh and bronchitis is also decreased.

As regards feeding, the author constantly finds ulceration produced on the end of the vomer from improper use of the spoon. The tendency of fluids to escape from the nostrils may be obviated by raising the child up. The mother's milk should be saved when possible, and the child should be fed with it from an old-fashioned, flat feeding bottle, provided with a large teat with a good-sized hole in it. The bottle should be slowly raised to pour out a little milk after each act of swallowing.

Regarding the operation itself, the author lays stress upon the great importance of freely separating the lip on each side from its bony attachments, the object being to allow the lip to move freely over the bones, so that the margins may be brought into apposition. He believes that the importance of this point has not been fully brought out or realized, and that its inadequate accomplishment has been a more frequent cause of non-union—in cases which otherwise promised well—than all other causes of failure put together. In complicated cases the thoroughness of the separation is the guarantee of success. In such cases the lip and ala nasi, and the contiguous cheek, require a free but careful separation from the bone for a considerable distance outward. A modification of this practice, which he has found of considerable advantage, consists in carrying the knife round the base of the ala nasi and continuing the incision in a curved direction upward, following the natural groove between the ala and the cheek. This upward incision does not need sutures, for, when the lip is brought together, the ala falls readily into position, and the resulting cicatrix is scarcely discernible. In following this practice the ala should not be detached from their bony connection, lest they manifest a tendency to evert and show more of their inner aspect than is natural.

The next point is the appropriate treatment of the prominent alveolar process. Where the alveolar ridge on one side is much in advance of that on the other, the general practice is to divide the process partially some little distance from the cleft and forcibly press it into position. He strongly advises that, when the two portions of the lip can be brought over the projecting process and secured without undue tension, the prominent bone should not be divided or bent into position.

In the greater number of these cases, even when the gap in the palate is wide, and the projection of the alveolus not inconsiderable, a successful result may be assuredly expected without any such interference. The curing of the harelip alone is sufficient to depress the alveolus and diminish the gap to a remarkable extent, even in one week, while in a month or two the gap will be found closed, and the alveolus reduced to its proper level. Such is the powerful action upon the bony process of the comparatively slight pressure of the restored lip. Moreover, interference with the bone is not inintensely followed by a mild degree of septicaemia.

When, to accomplish the operation, it is absolutely necessary to reduce the level of the projecting alveolus, a pair of fine-bladed bone nippers, or a strong pair of surgical scissors, should be used in preference to the ordinary bone forceps, which crushes the structures too much. They should be applied in front of the lateral incisor, and in such a way as to divide the bone partially, and enable it to be pressed backward into the position desired. Lately, to effect this object, the author has employed a small and very fine osteotomy saw. It is only necessary to cut through the anterior plate of the alveolus partially, as high as the nostril, after which he has found that the bone could be easily bent back into position. By this method no tooth-sac
The Exposition of Goitre.—Dr. Julliard ("Rev. de chir.," No. 8, 1883), after an analysis of thirty-one cases of extirpation of goitre, arrives at the following results: He asks, Is it necessary to extirpate goitre? Should one operate on all cases indiscriminately? If not, What are the cases in which extirpation should be performed? The answer to these questions involves the consideration of the following points:

1. Is or is not the goitre a disease dangerous in itself and capable of causing death? To this he unhesitatingly answers in the affirmative. The growth may compress the trachea, may change its position and profusely alter it, so as to cause respiratory troubles and pulmonary affections which eventually carry off the patient. The author has known of six fatal cases in the last five years. It is a mistake to consider goitre (he does not include benign goitres or malignant tumours of the thyroid) as a harmless affection, which has no other inconvenience than the deformity it may cause. On the contrary, goitre kills its man, and more often than is supposed—at least in Geneva.

2. Though goitre often causes death, it more often is an entirely benign affection. Every day we see patients reaching an advanced age in spite of a goitre, sometimes very voluminous, which has never troubled them except by the deformity it has produced. In a word, there are goitres and goitres.

3. We have in medication with iodine a precious means of curing goitre. On this point the author does not agree with those who hold that goitre is never cured, and that extirpation is the only radical treatment to oppose to it. He has seen too many cured completely, or at least reduced to a size that rendered them entirely inoffensive, to hold any such view.

4. Extirpation is not at present an operation to be looked at too seriously. It gives results as satisfactory as many other of the large operations at which nobody hesitates; but it exposes to secondary accidents which must be taken into account.

Every goitre, whether suffocating or not, should first be treated with iodine. If the medication succeeds, if the goitre is cured, or if the accidents which it causes disappear, all is well, and there should be no surgical interference But, if the goitre, insensible to iodine, troubles the respiration of the patient, and especially if it causes attacks of suffocation even light and at long intervals; if it is deep and only slightly movable, no matter what may otherwise be its volume—it is necessary to remove it, because these goitres always end, at one time or another, badly for the patient. The extirpation should be partial if possible. Otherwise it should be complete; for it is better to live by running the chance of the accidents which may follow total extirpation than to die choked by a goitre. Action should not be delayed. The more one waits, the more complicated and dangerous will the operation become. It is in consequence of temporizing that goitres are allowed to develop and produce such changes that extirpation has scarcely a chance of success. The greater number of unsuccessful extirpations are due to the fact that the operation is done too late. Among the author's five patients he counts four which might as well have been saved as the others had the operation been done earlier.

On the question as to whether an operation should be done in cases where the goitre causes no accidents, where the operation is simply a matter of aesthetics, two opinions are found. According to some, an operation should always be done without hesitation; according to others, they should never be touched under any pretext. The author holds to neither extreme, and decides each case for itself. If the goitre is small, causes little trouble and disability, there should be no hesitation in refusing to operate. If it be large, and at the same time patulous on the surface, and limits itself to enlarging the neck, one should abstain also, for here the deformity may easily be concealed by the toil, and because, again, extirpation in these cases is always a serious matter. Large goitres, not prominent, are always deep, and in these cases the inconvenience of the tumor is not in proportion to the danger of the operation. But, if the goitre is at the same time large and prominent, one need not fear to interfere; for here the deformity can not be concealed, because the extirpation of a salient goitre is much less dangerous and more simple than that of a deep one, and because one may limit himself to removing the salient part of the tumor without entirely removing the gland. The dangers of such an operation as this are not such as to justify one in systematically refusing a patient to relieve him of a deformity which is often a veritable calamity.

In the author's statistics it will be seen that of his thirty-one operations six have been of cysts of the thyroid. Up to the present time extirpation has been confined almost entirely to paragranulomatous tumors. Cysts of the thyroid have been treated by other methods: the chief of which are drainage, seton, cauterization, injections of iodine, non-antiseptic incisions in which the sac suppurates and is obliterated by granulations, and antiseptic incisions in which obliteration of the sac is obtained without suppuration by approximation of the walls. Let us examine a little the value of these operations as compared with extirpation. The author rejects all proceedings which are based on the suppuration of the sac, such as drainage, the seton, cauterization, and non-antiseptic incision. They are all apt to be followed by suppuration which may last for months, and they expose the patient to the risks of gangrene, purulent infection of the cellular tissue of the neck, and hence to purulent infection, without speaking of fistula and returns. All these methods should be abandoned by surgery, for there are better ones at her disposal. Injections of iodine and antiseptic incision are alone worthy to be preserved, and to both of these the author prefers extirpation.

The injection of iodine is the method generally adopted, and it meets with numerous successes; nevertheless, there are serious objections to it. In the first place, it is often ineffectual. A return of the disease is a common occurrence, and, if the cavity is not spherical, if the cyst presents anzlectostomies, if the walls are thickened, or if the fluid is not serous, they are the rule. In the
second place, injections of iodine are inapplicable to those cysts which are hemorrhagic, and to those which are divided into compartments. But these are minor faults. The great objection in the author's mind is that the treatment is liable to be followed by serious accidents, the most important of which are:

1. The inflammatory swelling which always follows the operation. This is said generally to be moderate. Nevertheless, it does occasionally happen, and this without its being possible to foresee it, that the swelling passes the proper limits. If the excessive swelling in a case of hydrocele is not a serious matter, in a case of thyroid cyst it is very different. Here, if the tumor be a little large, and if it already interfere a little with respiration, the surgeon is in danger of seeing his patient die in an attack of suffocation. The author has had this experience once, in a cyst of moderate size which interfered a little with the respiration, and has never been induced to repeat the performance.

2. Suppuration is a frequent result of injection, and one equally impossible to foresee. Suppuration is a very serious matter, because the pus in the cysts has a great tendency to become putrid. The number of patients who have died of purulent infection following the suppuration of a cyst is much larger than is generally supposed, and to the reported cases many unreported ones may be added.

The operation by antiseptic incision consists in incising the whole length of the cyst, perhaps excising a part of the sac, and closing the walls and the skin with sutures after placing a drainage-tube in the most dependent portion. The walls thus approximated become adherent, and the wound closes by primary intention. This procedure the author prefers to any irritating injection, because there is no danger either of swelling or infection: but to it also there are serious objections. Thus, like iodine injections, it is inapplicable to cysts called hemorrhagic and to those which are multilocular. Moreover, it is not free from relapses and fistula. The operation is based upon immediate union of the walls of the sac. In order for this to happen, the walls must be exactly approximated through their entire extent. But if there are anfractuosities in the cavity of the cyst, if there are diverticula in its deeper parts, if, again, the walls of the cyst are thickened and rigid, the exact approximation of the walls becomes exceedingly problematical; and if there remains a single point, no matter how small, at which the walls are not approximated, it will suffice to cause a relapse or a fistula.

If the cavity of the cyst is regular, if there are neither anfractuosities nor diverticula, if the walls are thin and supple, the author recognizes that an exact approximation may be obtained without much difficulty. But even in cases such as these the conditions for adherence of the walls leave much to be desired. It must not be supposed that, even in such cases, things will go on as easily in an incision into a hydrocele, for example. When the operation of incision into a hydrocele is performed, we have to do with a serous membrane, and we know that when serous surfaces are approximated the spontaneous tendency is to adhere. But it is not by any means the same with the surface of a thyroid cyst. Not only is the internal wall of the cyst not covered by a serous membrane, but it is covered by epithelium. Now, in approximating two epithelial surfaces, the function of which is to secrete a colloid material, we are very far from realizing the same conditions for immediate union which exists when two serous surfaces are brought together; indeed, the conditions are much less favorable than when two bleeding surfaces are brought together, as in extirpation. And, if we have already met with relapses following incisions into hydroceles, how much more may they be expected, as also incurable fistula, as a result of incision into thyroid cysts?

For these reasons the author prefers extirpation to injections or to incision. To iodine injections, because it does not expose to swelling, to suppuration, or to infection. To incision, because it does not expose to relapse or to fistula. To better understand his thought, the author divides these cysts into three categories. The first comprises those called hemorrhagic and the multilocular. There is no discussion, he thinks, as to the rule that these should be treated by extirpation. In the second category he ranges the unilocular cysts—those in which the cavity is irregular and has prolongations more or less deep, those in which the walls are more or less thickened and rigid, those in which the walls are rigid, which interfere, if only slightly, with the respiration, and of which the contents are not serous. For such as these the swelling following injection may have serious consequences, as may also the suppuration—consequences equally impossible to predict or prevent. As for relapse, it almost always happens, and is the least of the inconveniences which may be expected. As for the antiseptic incision applied to this form of disease, the author predicts more relapses and fistula than successes. The third category comprises the unilocular cysts, in which the cavity is irregularly spherical, without either prolongations or anfractuosities, in which the walls are thin and supple, the liquid of which is serous, and which are small, prominent, and superficial. These are the triumph of antiseptic incision and of iodine injection, but they are equally the triumph of those in which extirpation is simple and easy. To inject one of these cysts is to expose it to relapse, to inflammatory accidents, and to suppuration; and this is not the case if it be extirpated.

Extermination is as easy and sure as incision. The author can understand how one may prefer injection to extirpation, because the former is not usually considered as a surgical operation. It causes no loss of blood, and when it succeeds it leaves no scar. But when the history is once in hand he can not see why one should prefer incision to extirpation. Extermination is a little longer than incision, and that is all; but it is not more painful, it is not more dangerous, for there is no occasion for interference with the carotid or jugularis, with the recurrences or pneumogastrics, and there is no retrosternal pouch. It heals as quickly and as well as an incision, if not better, as the reader may convince himself by reading the author's cases; the cleft left is the same as in incision; and with it one is at least certain not to have either relapse or fistula, which is more than can be said for incision.

(To be concluded.)

Miscellany.

THERAPEUTICAL NOTES.—The Treatment of Sebaceous Cysts by Injection of Ether.—In the "Bulletin général de thérapeutique," for November 30, 1883, M. Lermoyez, intern at l'Hôpital Saint-Louis, Paris, describes M. Vidal's method of treating sebaceous cysts by means of injections of ether. Using a Prazor's syringe, and inserting the point into the largest of the apertures that come into view when the tumor is made tense by pressure, from five to ten drops of ether are injected into the sac, the quantity to be varied according to the size of the tumor. This causes no pain beyond the slight discomfort due to the distension of the sac, and it is to be repeated every second day until signs of inflammation make their appearance. Then a puncture is to be made at the base of the tumor, and a small amount of pus will escape. This is followed by the sebaceous matter, broken down into a vermicelli-like mass, together with shreds of membrane, the remains of the cyst-wall. The tumor is then found to have disappeared, leaving in its place nothing but a slight and transient thickening of the subcutaneous connective tissue covered by perfectly sound
The process of cure usually takes no longer than from ten to twenty days, and never causes any fever, or even headache. Mr. Vidal has employed the method in the cases of several patients who occupied beds in a ward where there were erysipelas patients, but in no instance did infection take place. It is considered desirable to move the point of the syringe about somewhat after it has entered the tumor, and before the ether is injected, in order to break up the seraceous mass and irritate the lining membrane of the cyst. The ether should be injected gradually, and injection should be stopped so soon as the patient feels a sense of distension. There is no occasion for the patient to give up his usual course of life during the cure.

Choreic Cough.—Dr. J. Mortimer Granville writes as follows to the "Medical Times and Gazette":

"Attention has recently been directed to what is called 'laryngeal chorea.' The laryngeal muscles are commonly implicated in the disorderly movements of chorea which has attained any degree of development; and there is a well-known form of cough which is analogous in its nature and causation with the cough of this new, or rather newly described, disease—laryngeal chorea."

"It is, however, with regard to another form of the same nervous trouble that I wish to call attention to offer a few remarks and suggestions. Young persons of either sex, but particularly the female, are very commonly affected between the ages of fifteen and twenty with a cough which is laryngeal, and characterized by a peculiar metallic ring, either 'cracked' or 'whistling,' during the inspirations, and often producing in the intervals of the paroxysm 'hoarseness,' 'squeaking,' or 'loss' of voice. The fault is irritation of the recurrent laryngeal nerve, and it very often happens that the pharyngometer is also irritated to such an extent as to give rise sometimes to gastric disturbance, at others to faintness from slowing of the heart-beat, or 'palpitation' from temporary suspension of the inhibitory control of the vagus. If the trouble ended with this it would be of minor importance; but the gastric or cardiac irritation set up, and the cough, together, besides giving rise to mistakes as to the general condition of health, actually, as I believe, favor the occurrence of nutritive changes in the bronchial membrane and submucous tissue, which induce a low inflammatory action, and issue in the exudation and deposit of tuberculous lymph. Hence we get the class of cases which are thought to have 'nothing wrong with the lung' except bronchial irritation, but which too often end in rapid tuberculous phthisis, and death. They are, in truth, cases of 'bronchial irritation'; but the irritated structure is the nerve, and, consequently, there is no natural limit to the disorder which may ensue. Practitioners who have much to do with the younger members of families will recognize the affection of which I speak.

"Now, I believe there is only one method of treatment which is quick and completely successful in putting an end to the morbid state of irritability whence arise all the phenomena that go to make up the misleading and mischievous affection of 'pulmonary weakness' or 'throat cough' as it occurs in the adolescent. It is not a pleasant remedy, nor, on the other hand, is it a very formidable one. It is briefly this: to paint over the course of the pharyngometer nerve, or (which is sufficiently near for the purpose) along the anterior margin of the sterno-cleido-mastoid muscle, a space extending from the level of the lowest margin of the lobe of the ear to the sterno-clavicular articulation, and about one sixth of an inch in breadth, with liquor vesicatorius or glacial acetic acid. This should be done first on one side, and, when the blister has healed, on the other side, commencing with the side on which there may possibly be found some indications of what is fashionably called 'hang weakness.' If the first application does not put an end to the cough, another should be made about a fortnight afterwards—the sides being blistered alternately—and the treatment continued until the symptoms entirely disappear, which will generally be within two, or at most three months. No medicine need be given, except, perhaps, small doses of cod-liver oil, if there be any loss of flesh. In this case the dose ought not to exceed one teaspoonful twice or thrice daily, being taken about two hours after a meal. I would strongly urge those who have to treat cases of the class to which I refer—namely, of choreic or 'nervous' cough—to try the method described, which I believe to be in a signal degree effective."

Operative Procedures in Cases of Intestinal Obstruction.—Mr. J. H. Morgan, in a paper read before the British Medical Association ("Br. Med. Jour.," October 9, 1883), makes the following suggestions:

Given a case of intestinal obstruction in which, by auscultation and other methods, the integrity of the colon may be presumed, the median line seems to offer the most favorable situation for the incision, since from it every region of the abdomen can be explored, the risk of hemorrhage is diminished, it is not ill-suited for the formation of an artificial anus, and it can be extended, if necessary, in a vertical or lateral direction.

Exceptions to this rule may occur:
1. In the case of hernia reduced en masse.
2. In the case of foreign bodies, gall-stones, etc., which can be felt from without to be impacted in the intestines.
3. In the case of tumors external to and pressing upon the gut.

Under any of these circumstances it may be advisable that the incision should be made directly over the region in which strangulation may be presumed to exist; but the middle line may still be preferable in the third case when the tumor is ovarian, or where, notwithstanding the pressure of a tumor, the compression is caused by a band which passes from it to some other portion of the abdomen.

It has, moreover, been shown that, if the obstruction be found after all to be situated in the colon, a median incision does not forbid the subsequent operation of colotomy, or the removal of a cancerous growth. It is to the mode of finding the seat of the obstruction after the abdomen has been opened, a valuable hint has lately been given by Dr. Kingston Fowler, who points out that the collapsed portion of the bowel, which it is so important to secure, will, in these cases, be found in the pelvis, and may be most easily reached toward the right side.

Bands are most frequently situated in the right lateral region of the abdomen, and, when found, may be divided at the center or at each extremity; but it should be noted that many cases are recorded in which, one band having been released, the symptoms have persisted, and post-mortem examination has shown the existence of a second band causing constriction. Its absence should therefore, if possible, be determined before closing the abdomen.

Or it may be advisable to remove the cause of construction altogether, as where intestine is already in a state of gangrene. In this case the desirability of re-establishing the continuity of the tube by union of the sound portions of intestine is greater in proportion to the distance of the constriction from the stomach. In one of Kocher's cases, forty-two centimetres of gangrenous gut were removed, and recovery followed. Billroth's cases of pyloric incision show how large a part even of the upper portion of the tract may be removed without destroying the digestive function.

The argument against excision, that it is frequently followed by stricture, requires further demonstration before it should be permitted to tell against the operation.

All present observations indicate the desirability of earlier diagnosis and of earlier surgical interference in proper cases.

Hysterical Fever.—Dr. Briand ("Gaz. h.

Oct., 1883) maintains, in opposition to H. Pinard ("De la pseudo-

hystérie," Thèse de Paris, 1883), that this complaint is not a mere counterfeit, since, in several cases carefully observed by himself and others, the bodily temperature has exceeded 100° Fahr. He still adheres to the conclusions put forth five years ago in his own gradua-

tion thesis on the same subject. These are as follows:
1. Febrile symptoms undoubtedly arising from hysteria are of fre-

quent occurrence.
2. The slow hysterical fever first noticed by Briquet is not the only form which the fully developed affection may assume.
3. There is another, generally primary, and of brief duration, which resembles typhoid. It is in this form that the bodily temperature is highest.

An intermittent variety of hysterical fever is also met with—es-

pecially under the last of the above-mentioned types—and in this the temperature is comparatively low.

Retention of the Placenta as a Safeguard against Secondary Hemorrhage from Atony of the Uterus.—Dr. E. Thorburn ("Critical-
MISCELLANY.

The Mutability of Bacteria.—The question whether the same germs under different conditions give rise to various diseases has been raised, but not settled. Dr. Carpenter, at the meeting of the British Association, treated the subject from a point of view of natural history. He referred to the facility which the lower forms of life possess of adapting themselves to changed conditions of existence. He believes that the same germs may under altered circumstances produce various diseases, and these opinions he supported by various arguments. The decrease of the virulence of the small-pox which ravaged Europe in the fifteenth century he attributed to the cultivation of the mildest cases which occurred. A severe attack of any particular disease may so affect the system that a disease arises which cannot be recognized as related to that from which it proceeded. Under favorable conditions an ordinary intermittent fever may develop into a virulent form, which is highly contagious. There is, in his opinion, very strong ground for the belief that even the innocent hay bacillus may undergo such an alteration in its type as to become the germ of severe disease.—\textit{Lancet}.

Mediterranean Fever.—In the report on the health of the troops serving in the Mediterranean in 1881, the officer in charge of the station-hospital at Gibraltar, Brigade-Surgeon Fuller, thus describes his experience of Mediterranean fever: "It is characterized in mild cases by ordinary febrile symptoms, with lassitude, debility, and slow convolution. In severe cases there is great prostration, with profound perspiration. In some the lungs posteriorly become rapidly consolidated by engorgement; in some there is brain-congestion and low nutriment delirium; in others there is bowel-complication closely resembling enteric fever. Death may occur from any of these complications. The fever sometimes runs a very protracted course, unattended by any complication, culminating in an altered or morbid state of the blood, and a condition of profound prostration complicated with purpura. After defervescence, in a very large number of cases, a rheumatic affection of the fibrous tissues around the joints and other parts supervenes. The duration of this stage of the disease may extend over an indefinite period; in some it may be counted in months. The cause and nature of this fever are still unknown, but it is proved beyond doubt that it is neither enteric, malarial, nor relapsing. My own idea is that the cause is to be found in climatic peculiarities. When there has been bowel-complication, there is leuken-colored congestion of the duodenum and upper part of the jejunum. The albumen is generally healthy; Feyer's patches unaltered. In one case the patches were observed to be very slightly swollen, but not sufficiently to be pronounced diseased; large intestines healthy."—\textit{Med. Times and Gazette}.

A New Theory of Asphyxia.—In traumatic shock, stator, collapse, apoplexy, syncope, etc., there is, according to Brown-Sequard, an increase of the blood circulation; inhibition of the normal gaseous interchange of the tissues, so that venous blood becomes like arterial—deep red, rich in oxygen, and poor in carbonic acid. Any kind of injury to the nervous system, stimulation of the skin and mucous membranes, poisons (especially if sudden in their action), etc., produce this nervous inhibition. Asphyxia differs from this not only in the condition of the blood, but in the absence of convolution, the blood-filling of the left heart, and the greater duration of the irritability of the nervous and muscular systems.—\textit{Med. Times and Gazette}.

Antiseptics and House-Surgeons.—While an increased faith in the efficacy of strict antiseptic precautions must of necessity follow the brilliant results obtained by Professor Lister in his treatment of fractured patella, the remarks made by him at the last meeting of the Clinical Society on the subject of attention to the details of dressing should be seriously taken to heart when dangerous operations are undertaken. The suggestions thrown out—by one surgeon, that the septic condition of a wound might have been due to the absence of the regular house-surgeon upon his holiday; and by another, that similar want of success might have been the result of a little assistance rendered during the operation by a colleague with unwashed hands—are instructive. Much of the opprobrium of failure of antiseptic precautions in hospital cases must of necessity fall upon the house-surgeon or dresser, if, as in some large hospitals, the latter is placed in responsible charge of his cases. If a house-surgeon is to be thoroughly versed in all the details of antiseptic dressing, so as to be equal to the emergency-practise of a large hospital, he must have been brought up, as it were, in an antiseptic or Listerian atmosphere, and his mind must be imbued with a persistent enmity toward all sorts and conditions of germs, and accustomed to regard the honest patient as a barbaric contrivance of a bygone age. But house-surgeons and dressers must in their turn enter upon the general practice of surgery and be prepared to treat cases and to operate under circumstances where antiseptics can not be applied. Here their knowledge of the manners and customs of disease-germs and their contempt for the efficacy of the poultice will avail them but little, and patients may suffer in order that their medical attendants may theorize. Until the day, predicted by Professor Lister, arrives when rigid antiseptic rules shall be universally applied, the custom of restricting the student to the practice of one surgeon only will be followed, as it frequently is at present, by the unsatisfactory consequence that the \textit{general} experience of surgical practice has to be learned at last instead of at first. But Mr. Lister insists that the success of antiseptic treatment depends largely upon the antiseptic training of those who have to carry it out. Perhaps the best way out of the difficulty is that suggested by himself, viz.: that surgeons should attend daily and see to their dressings themselves.—\textit{Med. Times and Gazette}.

Natal Intelligence.—Official List of Changes in the Medical Corps of the Navy during the week ending December 15, 1883.—\textit{Surgical F. M. Dearbon} placed on the retired list from December 10th.

Passed Assistant Surgeon A. C. Heffinger, in addition to his duties at the Navy-Yard, ordered to attend officers at Portsmouth, N. H.

Society Meetings for the Coming Week. —\textit{Tuesday, December 25th: New York Dermatological Society (private); New York Surgical Society (private); Medical Society of the County of Lewis, N. Y.; Jersey City Pathological Society. Wednesday, December 26th: New York Pathological Society; American Microscopical Society of the City of New York; Autumn City (N. Y.) Medical Association. Thursday, December 27th: New York Academy of Medicine (Section in Obstetrics); Harlem Medical Association (private); Brooklyn Pathological Society. Lectures and Addresses.

A CLINICAL LECTURE
ON SOME
NERVOUS AFFECTIONS IN CHILDREN,
DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

By Horatio C. Wood, M.D.,
PROFESSOR OF MATHEMA MEDICA AND PHARMACY, AND CLINICAL PROFESSOR OF NERVOUS DISEASES.

Infantile Paralysis.—Diphtheritic Paralysis.—Chronic Inflammation of the Cortex of the Brain, following Meningitis.

Case I.—Gentlemen: The first patient I shall show you was at the hospital six years ago. The history which I find in the books is as follows: "August 19, 1876, A. B., aged nineteen months, living in Pittsburgh. About last Christmas the child fell out of bed, a distance of twelve or eighteen inches. It had always been healthy, and for a week or two after the fall nothing wrong was observed. The child then began to have high fever, vomiting, and convulsive jerking during sleep; these symptoms continued for several days. After they had passed away it was noticed that the left arm was paralyzed. At first it could not be used at all, but later some improvement occurred. There was much atrophy of the arm, but no decided lowering of temperature. The treatment consisted in the administration of phosphorated-oil mixture and the use of electricity. The child improved considerably and returned to Pittsburgh."

We have, then, a history of a fall which may, or may not, have had something to do with the attack which followed. About a week afterward the child was seized with high fever, jerking of the muscle, and some delirium which lasted for one or two weeks. It was then discovered that one arm was paralyzed. He was brought to the dispensary, and the left arm was found to be distinctly atrophied, with great loss of power.

This was, then, a case of monoplegia. As you know, monoplegia is paralysis of one extremity, while hemiplegia is paralysis of a lateral half of the body, practically palsy of the leg and arm, and paraplegia is paralysis of the lower extremities.

In monoplegia the lesion is always located in one of three places—either in the cortex of the brain, or in the large cells in the anterior cornu of the spinal cord, or in the nerve-trunks.

Let us decide to what the monoplegia in this case was due. It may have been cerebral. The fibers of the spinal cord as they enter the brain spread out like a fan, so that, if you have a lesion where the fibers begin to diverge, there will probably be paralysis of several groups of muscles—a hemiplegia. But, if the lesion involves the cortex of the brain, only those muscles supplied by the individual bundle of fibers upon whose origin the clot impinges will be affected; monoplegia will result. Was the monoplegia in the child before you due to cortical lesion? The history of a fall on the head, the fever and the delirium, would seem to indicate that this might have been a case of meningitis, and that there was a clot or some other lesion affecting the cortex of the brain. If, however, the paralysis had been due to a clot following the injury, the palsy would have developed immediately more than this; the record says that the muscles of the arm were atrophied. The nutrition of every muscular fiber, and probably of every gland-cell, is under the influence of certain nerve-centers, and, when such a nerve-center is diseased, the part overseen, so to speak, by that nerve fails. The cortical nerve-cells are not the trophic nerve-centers of the muscles; and, therefore, whenever monoplegia is followed by rapid wasting, you know that the monoplegia is not of cerebral origin. Let me repeat this.

There is nothing in the history of the present case to denote a peripheral lesion. If the child had broken its arm, or torn the nerve, or pressed upon it, or if the paralysis had been preceded by intense pain, eruption of herpes and other indications of nerve lesion, we might think that this monoplegia was due to a peripheral lesion; for, as you can easily understand, when there is any lesion of the nerve separating the muscles from the trophic centers, there is wasting of the muscles, although the trophic centers themselves remain normal. From the absence of any history of nerve lesion, from the absence of pain in the arm, and the presence of very marked constitutional disturbance, we come to the conclusion that this child did not have a peripheral lesion.

If the monoplegia is not due to a cerebral or to peripheral lesion, it must be due to some disturbance of the large cells in the anterior cornu of the cord. You will remember that infantile or essential paralysis of childhood often begins with high fever, headache, and delirium, and may readily be mistaken for typhoid or malarial fever. In this child the attack came on like an attack of essential paralysis, and the results are those of that disease; consequently, we come to the conclusion that the child is suffering from the results of essential paralysis. As the record says, the child was treated with phosphorus and the application of electricity to the arm, but, after being under treatment for a short time, it was taken to Pittsburgh.

We now have an opportunity of examining it, after the lapse of five years. You see that the left arm is very much atrophied, but there is no complete paralysis of any one muscle, for the child is able to execute all the ordinary movements of the arm. The arm is not cold.

Essential paralysis in its acute form is rarely met with in adults, but very commonly in children, while, on the other hand, the chronic form, although rare in adults, is still more rare in children. The reason for this is, I think, found in the fact that in the child these cells are in a state of extreme activity. They are engaged not only in maintaining the strength of the muscle, but they are also building up that muscle; but in the adult, after full development has been reached and growth ceases, these cells pass into a comparatively inert condition. You know that it requires a stronger force to build a house than to keep it up after it is built. Whenever a tissue is in a state of high functional activity it is on the verge of over-action, and any attack
which it suffers almost of necessity takes an acute form. If a child has a congestion of the spinal cord, these cells are very liable to become acutely affected, and the simple congestion passes into polio-myelitis, while, if an adult has congestion of the cord, these cells do not respond, and when the congestion subsides all may be well.

In regard to the prognosis in this case, the child was first attacked six years ago. During the past five years there has been considerable improvement. We know that there is at present no disease going on in that child's spinal cord. We have only the results of the acute attack to deal with. We first want to measure, if we can, the amount of damage that has been done. When a muscle is separated from its trophic center there is a deterioration of that muscle, which can be measured by the electric current. The muscles first lose the power of responding to the faradie current, and later the power of responding to the galvanic current.

The muscles in this case respond to the galvanic current. If in a case like this the muscles fail to respond to any form of current, you can not expect to do much good by treatment. In this case the child may be much improved by persistent treatment, but it is not at all probable that the muscles can be restored to their full power. Very little can be done to restore the cells of the spinal cord, but we can bring up the nutrition of the muscles, and, as the existence of voluntary power and the electrical condition of the muscle here show that the spinal cells have so far recovered themselves as to be able to prevent a continued degeneration of the muscles, there is every reason to suppose that, if we can improve the nutrition of the muscles, the cells will be able to maintain the improvement.

In applying electricity to these muscles, the guiding rule is to employ that current which gives the greatest contraction with the least pain. The applications should be made every other day, and the treatment kept up for several months. Massage, careful gymnastics, and the hypodermic injection of strychnia will be found useful adjuvants, and, when you can command the use of the Gounod's boot with mechanical, very rapid vibrations of the limb, are, I am convinced, of service.

Cases II. and III.—Here are two patients who, although suffering from entirely different affections, have some curious symptoms in common. They both have an affection of the speech.

This boy (about nine years of age) was well until six weeks ago, when he had some sort of attack lasting three weeks. At the end of this time the speech became affected, and within a few days he had almost lost the power of talking. He seems as bright as ever, but wants to keep quiet all the time. He knows everything that is said to him. He staggers when walking. When hungry, he asks for food.

In the other patient, a girl of six years, the loss of the power of talking came on gradually, beginning about six months ago. Previous to this the child was very smart, but since then its mind has failed. She has become restless, worries, and cries a great deal. If left alone she does not ask for anything to eat, and does not play with her toys.

There you have a clear case of brain deterioration along with the loss of speech.

I ask the boy his name, and you observe the peculiar character of the voice. Whenever you hear that nasal voice acutely developed after a severe illness, you can be almost positive that the child is suffering from diphtheritic paralysis. The mother tells me that when the child was sick he had sore throat, high fever, his nose bled a great deal, and he was very sick. The voice which you heard is indicative of paralysis of the palate, and this paralysis is excessively rare from any other affection than diphtheria.

I do not remember ever seeing acute paralysis of the palate unconnected with marked cerebral symptoms from any other cause. The boy can swallow solids quite well, but not fluids. The girl seems to have some difficulty in getting the food to the back of the mouth, but when she gets it there it is readily swallowed.

There may be a partial paralysis of the lips and tongue, causing a difficulty in taking food, but when the food reaches the gullet it is readily swallowed. This is not a real but a seeming difficulty in swallowing. A real difficulty in swallowing may be due to a muscular affection, spasmodic, paralytic, or rheumatic, or it may be due to an obstruction from post-pharyngeal abscess, etc. In order to diagnose between paralytic and organic difficulty of swallowing, we inquire whether solids or liquids can be taken best. If there is an organic difficulty, as, for instance, when a child has a post-pharyngeal abscess, or an adult has a stricture high up in the esophagus, the patient can swallow liquids better than solids, while with a paralytic difficulty he can swallow solids better than liquids.

In the girl we know that there is no affection of the palate muscles, that there is slight palsy of the lips and tongue, and that the trouble is due to some disease of the brain, for there is loss of mental power, complete change in the disposition of the child, which has been going on for months, associated with either a paralysis of the parts concerned in speech or else with aphasia. I said that this was associated with paralysis. I may be wrong. It may be due to a loss of the power of thinking words. But, on inquiry, the mother tells me that the child slobbers a great deal, and you can see that there evidently is lack of power of the labial muscles to keep in the saliva. There must be somewhere in that child's brain a progressive lesion, probably at the base of the brain. The probability is that this child has had an attack of meningitis, and this meningitis has led to inflammation of the cortex of the brain.

In the other case the diagnosis rests upon the history of the palsy having followed sore throat, and upon the character of the paralysis. The true nature of diphtheritic palsy is not thoroughly made out, but it is almost certain that it is the result of a peripheral lesion—that is, an involvement of the motor nerves. It especially affects the parts about the throat, because it is here that the original lesion is most marked. Although the paralysis nearly always affects the throat primarily, yet, in many cases, it involves other parts of the body. This child is weak all over. His mother says that his sight is affected. This is probably due to loss of
the power of accommodation from palsy of the intraocular muscles.

Diphtheritic paralysis usually terminates in recovery, and, unless the case is exceedingly severe, you can give a favorable prognosis. I have known of one or two cases in which death resulted, but this is rare. In regard to the treatment, rest is of the first importance. Many cases of diphtheria have terminated fatally in which result could have been avoided if the physician or parents had realized the importance of rest during convalescence. There can be no doubt that the cardiac nerves, or the cardiac muscle itself, shares in this paralytic condition. In all severe cases directly after the attack, especially if there is marked palsy, the child should be kept perfectly quiet. Later in the attack you permit some exercise, always avoiding over-exertion. Passive exercise, massage, rubbing, and especially the application of electricity, are of value. Strychnia is also of service. It should be given to the point of producing distinct evidences of its action.

The treatment immediately after the attack should, then, consist in absolute rest, the careful administration of strychnia, and the application of electricity to the affected muscles.

Original Communications.

CRITICISMS ON THE SPECIFIC THEORY OF HYDROPHOBIA.*

By CHARLES W. DULLES, M.D.,
Surgical Registrar to the Hospital of the University of Pennsylvania.

Nearly two years ago I had the painful experience of being summoned one day to take charge of a boy who was suffering with what is called hydrophobia. The unfortunate patient was under my care and observation less than twelve hours, when he died. The horrors of that day can only be understood by those who have had a similar experience. To stand in the presence of such distressing psychical disturbances, to see death advancing relentlessly, to feel that science furnishes no satisfactory explanation of the nature of the disorder and offers no trustworthy remedy for its treatment—this was a trial of mind which intensified the weariness of body which the circumstances necessarily entailed. The details of the case were read before the West Philadelphia Medical Society, and are recorded in the "Medical News," May 27, 1882. There can be found all the points which at the time most impressed me. There, too, are recorded the theoretical and practical notions in regard to hydrophobia which I had at that time. Later, on May 23, 1883, I read before the Philadelphia County Medical Society a paper entitled "Remarks on Hydrophobia," which was published in the "Philadelphia Medical Times," August 11, 1883. In this are set down some of the conclusions which I had reached after more than a year's study of the literature of the subject. The point aimed at in that communication was to attract the attention of those who heard me to the extremely unsatisfactory condition of our knowledge in regard to this disorder, and to lodge in their minds the suspicion that the views so ordinarily held, and so positively stated, in most of the text-books, are not as clearly established as most people believe. In concluding the discussion which followed in the society, I stated all I wished to at that time, of my own convictions, in the expression that "but little of the evidence upon which it (the commonly-accepted theory of hydrophobia) rests can be regarded as having an accuracy and reliability commensurate with the delicateness and gravity of the questions at issue."

Since then I have continued my investigations, and, the wider their extent has grown, the firmer has become my belief that this statement was the very mildest that could have been used without sacrificing the truth. But I have learned, by reading and by experience, that those who differ from the majority are in danger of being treated to a certain amount of disdain for their inability to accept as evidence what to others seems acceptable enough. For example, Dr. Parry, in his interesting work on "Cases of Tetanus and Rabies Contagiosa," published in London, 1814, indicates his sentiments as follows: "It was formerly doubted whether any such disease as canine hydrophobia existed; and I have heard that the question was once solemnly debated in a society which, after a long discussion, determined it in the negative by a majority of voices. The existence of the giraffe, or camelopardalis, was long denied by the moderns, not only notwithstanding the accounts given of it by the ancients, and its delineation on the Prenestine pavement, but after its skin was actually to be seen dried and stuffed in a Dutch museum. We are told of a king of Siam, who, after he had heard with patient attention certain wonders from a European ambassador, and was at last informed by him that in his country, at certain seasons of the year, water became solid and was capable not only of being cut or broken, but of admitting his Majesty and his whole court to walk over it without wetting their feet, flew into a violent passion, exclaiming: 'For a long while, notwithstanding the prodigies you have related to me, I thought you were an honest man, but now I am sure that you are an impudent liar.' In this story the intention that our knowledge about hydrophobia has reached the "dried-and-stuffed" stage goes well with the other intention: that the skeptics in regard to it are in the state of ignorance comparable to that of the king of Siam.

Later than Dr. Parry, but still in this century, Dr. Copland set the stamp of his learning on the doubters thus: "The supposition lately published that there is no such specific disease as rabies, and that it is merely the result of mental anxiety, etc., is only one of the absurdities thrown up on the surface of medical doctrine, and hardly deserves mention, much less serious refutation."

But scientific questions are not settled in this summary way, nor has the fear of being thought singular ever long deterred men from asserting what they had come to hold as convictions. That which has been branded as an absurdity has, over and over again in the history of the world,
come to be established as a fact, and the same may yet be accomplished for the opinion of those who deny the specific nature of rabies or hydrophobia. One thing is sure, viz.: that the attitude of severe criticism seems to offer the only hope for the solution of the riddle of hydrophobia, since, in more than two thousand years, the acceptance and repetition of authoritative opinions have failed to furnish a theory which does not fly in the face of all analogy, or a practice which holds out a reasonable hope of saving a single life. Such is the real state of knowledge in regard to hydrophobia. The theories as to its nature are contradictory and illogical, the teachings as to its treatment are without the slightest hope of success. In regard to both, the ablest men who have discussed it occasionally or systematically are in irreconcilable opposition. While some hold to certain modes of communication, others sternly deny them. While some admit its spontaneous origin, others will not admit it for a moment. While some think the virus is to be found in the saliva, the blood, the bronchial mucus, the milk, the flesh of rabid animals, others limit it to the first of these alone. In regard to the period of incubation, the widest divergence of opinion exists. The range is from one day to forty years, and no one seems to have been able to fix a limit to either its shortness or its length. Equal contradiction meets the gaze when one turns to the matter of treatment. From the throwing into a fish-pond, as practiced by Celsius, to the inhalation of oxygen, as recently practised by Drs. Schmidt and Zebeden, there is a variety of methods which demonstrate how utterly every attempt to find a specific has lacked the guidance of any accurate idea as to the nature of the disorder. To almost any statement of men whose names are highly respected in medicine may be opposed the most positive and contradictory statements of others equally respected. Virchow admits ("Handb. d. spec. Path. und Therap.," "Wathkrankheit und Wasserschcn") that hydrophobia may be communicated by means of weapons used to kill mad dogs with, and by blood-letting and scarifying instruments—a belief which, but for Virchow's adherence to it, would be correctly designated as obsolete, and which is entirely unworthy of acceptance. Bollinger, a distinguished veterinarian, admits (von Ziemssen's "Cyclop.," art. "Hydrophobia") the possibility of infection by the migrations of animal parasites, such as fleas and lice.

The late Dr. George B. Wood admitted the possibility of hydrophobia being caused by the bite of birds, and explains why this does not often occur, as owing to the fact that these animals, like horses, asses, and oxen, do not usually bite ("Practice of Medicine," vol. ii, art. "Hydrophobin"). In view of these facts, it will not seem so remarkable that Sauvages believed the eyes of hydrophobic patients shone at night, like those of cats, or that he should explain this on "meaque de hydrophobiae theoriam, qua admissit in hoc morbo fluidum illud in phosphoricam activam et excitam" ("Nosologia Methodica, Vesaniae," vol. ii, p. 232). Nor can one wonder that Mead, about a hundred years ago, should have said: "The influence of the moon in these cases, I am convinced, is of some weight" ("Medical Works," art. "Hydrophobia," p. 62).

But, to return to modern times, what shall one think of the attempt of Doleris, the author of the, in many respects, admirable article on this subject in the "Nouveau dictionnaire de médecine et de chirurgie" (1881), to explain the assertion of the occurrence of spontaneous cases by saying that the disorder may be acquired from germs distributed in the air and earth, like "charbon"? Or, how shall we consider the willingness of Sir Thomas Watson ("Nineteenth Century Review," December, 1877) to accept the occurrence of hydrophobia by the infection of sucklings through the medium of the mother's milk? or his statement that the disorder does not occur in Constantinople or Africa, in both of which places it does occur?

But I do not wish to make too much of this aspect of the literature of hydrophobia. I wish to call your attention to the cause of the uncertainties which prevail in regard to it. This is, in my opinion, easy to point out. It is the too great readiness to accept any sort of testimony which may be offered as bearing upon the subject. This fault is to be found in almost all the works treating of hydrophobia, from the earliest ages to the present time. This led Pliny to father such absurdities as the following: "There is a small worm in a dog's tongue, known as "lytta" to the Greeks; if this is removed from the animal while a pup, it will never become mad or lose its appetite. This worm, after being carried thrice round a fire, is given to persons who have been bitten by a mad dog to prevent them from becoming mad. This madness, too, is prevented by eating a cock's brains; but the virtue of these brains lasts for one year only, and no more." And, again: "So virulent is the poison of the mad dog that its very urine, even if trod upon, is injurious, more particularly if the person has any ulcerous sores about him. The proper remedy in such a case is to apply horse-dung, sprinkled with vinegar and warmed in a fig" (Pliny, "Natural History," Book XXIX, Chapter 32, translated by Bostock and Riley). This same too easy acceptance of testimony led such a writer as Dr. Samuel Bardsley, in 1807, to accept the statement that hydrophobia could be communicated by the mere application of the saliva to the unbroken skin, and to cite with apparent approval a story of a man who had hydrophobia from kissing a mad dog previous to its being hanged (Samuel Argent Bardsley, "Med. Reports," London, 1807). And, most recently, it has led Bollinger, already referred to, to attribute the disorder to drinking the milk of an affected animal, and to the act of coitus (von Ziemssen's "Cyclopædia," 1875), while Mr. Williams, in his valuable work on "Veterinary Medicine," third edition, 1882, says rabies can be communicated through a "thin epidermis, without wound or abrasion."

These citations illustrate the most remarkable feature of the literature of hydrophobia. It would seem as if, when

* This curious idea is founded upon a reference which, when I hunted it up, I found to be a pure assumption of a Dr. Mcnca ("Lan-
cet," March 23, 1872, p. 429), that the occurrence of small-pox, thirteen miles northeast from Melbourne, where it was also present, was to be accounted for only on the supposition that it was conveyed by flies. It has been interesting to observe, in my investigations, how this sup-
position of Dr. Mcnca's has grown to a statement of an established 
fact, as it has been quoted by foreign writers.
once the mind has accepted a theory which contradicts all experience in other and fairly well understood diseases, it loses the ability to distinguish good evidence from bad. A striking illustration of this is furnished by Dr. Dolan, in his otherwise capital book on hydrophobia or rabies. In his second chapter this writer calls attention in detail to the rules laid down by Dr. Abercrombie, in his inquiries concerning the intellectual powers and the investigation of truth. These warn against the following fallacies: 1. Receiving as facts statements which are not facts, but opinions. 2. Receiving as facts statements which only assume the relation of facts. 3. Receiving as facts general statements, or the generalization of facts. Dr. Dolan then says: "Some writers, for instance, have maintained with much confidence that a particular state of rigidity of some of the limbs is distinctly characteristic of ramollissement of the brain. But further observation has shown that the disease may exist without this symptom, and that this condition of the limbs may appear in connection with other diseases. This observation of facts was in so far correct that this state of limbs does very often accompany ramollissement of the brain; the error consisted in giving it as a general fact, or a fact applicable to all cases of ramollissement, which is without foundation. Yet such statements, when brought forward with confidence, are often received as facts and rested upon as established principles, and then the facts by which their fallacy might be detected are apt to be overlooked or forgotten." To this reference the commonest sources of fallacy Dr. Dolan adds: "We are arming our readers against ourselves." And yet he goes on, apparently with his eyes wide open, to reproduce the fault he has just pointed out in speaking of ramollissement, accepting statements which ought not to be entertained for a moment in the discussion of so grave and delicate a subject, and admitting as genuine cases which are transparently spurious. I will give an example of this latter mistake which illustrates several points at once. Dr. Dolan gives in his collection of cases, and, after sifting his material, stamps as genuine, the following, from Romberg's "Diseases of the Nervous System":

"Case LXXIV.—Frederick L., male, aged six, bitten on the second finger of the left hand by a dog which had already bitten several other children. Result and time of attack, three months. Fatal, third day. Treatment: A few of the dog's hairs had been cut off to place upon the wound, which in eight days was completely healed. The treatment consisted in taking twelve ounces of blood from the arm, scarifying, and applying cantharides ointment to the eczema, rubbing in a sample of mercurial ointment into the inner surface of the left arm. Dr. Horn also visited the boy, and described his features as expressive of extreme anxiety, while his eyes told a tale of inexpressible misery. He implored that he might not be touched or bled again, as he desired nothing more than to be allowed perfect rest." The post-mortem was made on the 4th of September, 1829, twenty-five hours after death. The smell of putrefaction was already developed. The muscles were dark red. The lungs were charged with blood. The larynx, the trachea, and oesophagus were not abnormal in appearance. But the record says: "The redness of the heart was remarkable, the arteries and veins on its surface looking as if they had been injected. The mitral and aortic valves presented a scarlet hue, the trabeculae carneae were darker than usual, the internal surface of the aorta was of a bright red hue as far as the arch; the blood contained in the vessels was dark and fluid; the inner surface of the stomach was as pale as that of the oesophagus. No morbid change was found in any other abdominal organ. At the urgent request of the parents, the head was not examined."

The history of this case, as originally described in Romberg's book ("Nervous Diseases," translation, London, 1832), taken together with the post-mortem appearances, seems to me to show it to have been one of acute endocarditis, probably septicaemic. But no such idea seems to have entered the heads of the physicians who attended it. As a case of hydrophobia they went most heroically to work to treat it. Picture to yourselves the scene. Think of that little child, only six years old, tested with the useless and dangerous tests of hand-washing and mirror, and with urine sprinkled on his skin—the former showing nothing, the latter causing a paroxysm. Think of his being bled, the eczema being scarified and blistered with cantharides, and mercurial ointment being rubbed into his arm. Then fancy him, when the doctors came at him after an interval, imploring only to be left in peace, while they, with grim determination, bled him again and doses him with calomel, after which, to quote Romberg literally, "death came to his relief."

In reporting this as a case of hydrophobia, Dr. Dolan has followed the opinion of Romberg, who, when he recorded it, had never before seen a case. But it strikes me as a very piteous illustration of the truth of what White said ("Doubts of Hydrophobia," London, 1828) of the course of many cases. He described the usual alarm, the fear of the patient, the suspicion of the doctor, the test with water, the melancholy conviction of doctor and patient, adding: "The patient and himself, therefore, will soon make out a case—the one dies, and the other publishes an account of his end." Does it seem unfair to apply such an expression to such a case as has just been cited? On the contrary, does not the history of the case indicate that general eminence in medical science gives no guarantee of infallibility when this vexed subject is approached?

I have selected an illustration of the point I wished to make which should include two names well known and justly distinguished, because their very excellences add force to the proof they furnish that the possession of a theory which at the outset demands a certain surrender of the judgment will impair the freedom of the judgment at every subsequent step. Such it seems to me is the condition in which every believer in the specific nature of hydrophobia stands. The assumption of a specific virus, and which alone, is the originator of the disease in any individual compels its adherents to bend their judgment to accept the belief that there is a virus which behaves in a way contradictory to that of every other virus about which we have any positive knowledge. As Lorinser has said ("Wien. med. Wochenschrift," 1874): "We know very well the appearances produced, for example, by the bite of poisonous serpents, or by the poisoning of wounds with the poison of glanders, anthrax, syphilis, or cadaveric poison. There are, in general, always the manifestations of more or less rapidly developed inflammation, and of further distribution of the
poison through the lymphatics, veins, and lymphatic glands, which organs then, in like manner, manifest similar inflammatory symptoms. Nothing of the kind do we see in wounds made by the bites of mad dogs," etc. And, again: "We know, in all pathology, not a single infective disease which, in regard to the time and symptoms of development, bears the slightest resemblance to hydrophobia."

One might suppose that such a contradiction would lead observers to be constantly on the lookout to find some other way of explaining the phenomena of hydrophobia, and that everything that was presented as evidence in support of it would be subjected to the most rigid scrutiny. But the literature of the subject shows that the very opposite is the case. The post hoc propter hoc argument is the one which rules here. A careful perusal of a large number of recorded cases leaves the impression that they have not been studied with any idea that they might be something else than what they appeared to be. Though it is no secret that the dread of water is a symptom of a great variety of affections, one finds, over and over again, the ablest men resting a diagnosis on this, which is acknowledged by most systematic writers to be the least reliable of its signs. Another thing which has struck me in examining the records of cases is the readiness with which reporters, aware of the objection so often raised of the effect of mental influence, accept the statements of friends or the silence of patients in regard to it as evidence that it does not exist. I will give an example of this. In the "Berliner klin. Woche-enschift," September 15, 1879, Dr. Findelisen reports a case of a man who died of hydrophobia, and who is positively stated not to have known that the dog that bit him was mad, or to suspect that he had hydrophobia, or connect his disease with the bite. Yet the record states that, on the second day of his disorder, he cried out that he had been bitten by the "poisonous (gif tiger) dog," and was not crazy.

Another curious thing to be observed in the literature of hydrophobia is the way in which the madness of the dog is often—one might say usually—deduced from the diagnosis of hydrophobia in the man, instead of the diagnosis of hydrophobia being made to rest upon reliable evidence that the dog was really mad. It is, however, to find any proof whatever that a dog to which hydrophobia is attributed was rabid, this being, with rare exceptions, a pure assumption. The one phenomenon of a dread of water usually determines the conviction of the physician that he has a case of hydrophobia before him, and settles his opinion of any dog that may ever have bitten the patient, and can not now be accounted for. Nay, more: this mode of reasoning has led certain writers to the assertion that there may be a passing state in dogs in which they may communicate to a human being hydrophobia, but themselves recover. Thus is the struggle to support the specific theory kept up when circumstances seem to be most adverse to it.

Once more, and I am done for this occasion with objections to the anomalies which one meets in examining the basis upon which the general belief in regard to hydrophobia rests. I find in the recorded cases, with very rare exceptions, that, when once hydrophobia is suspected, every phenomenon that occurs during life, every lesion that is found post mortem, is unsatisfyingly set down as a feature of this disorder; and the idea does not seem to be entertained that many of them are grounds of suspicion that some other disorder is present. In this way all lines of distinction between hydrophobia and disorders which simulate it are erased; and it remains for every medical man who is called to a patient who has a dread of water, accompanied with exaltation of reflex excitability, to inquire for a bite or scratch of a dog or cat; if one can not be drawn out, to assume that it has been received and forgotten; then to make a diagnosis of hydrophobia; after which it is only necessary for the patient to die to make a complete record. If to this be added a careful microscopic examination of the state of the brain and spinal cord, the observer will have an exact counterpart of the process by which the famous conclusions of certain investigators—often quoted by those who have not taken the pains to go to the evidence upon which they are founded—were arrived at.

This suggests a brief consideration of the pathological lesions of hydrophobia. Notwithstanding all the diligent endeavors made to learn something from the post-mortem examination of the bodies of dogs and men that have died of rabies or hydrophobia, one might to-day adopt the language of Dr. Hart, who declares (Cooper's "Surgical Dictionary," art. "Hydrophobia") that these examinations afford "little else than a varied mass of symptoms, common to other nervous and blood disorders," and fail to "throw any clear light on the pathology of the disease."

I will not trouble you with the disappointed anticipations of the ancients in this connection; those of modern times are more instructive. The announcement by Hallier, in 1872, of the discovery of a micrococcos which was the germ of hydrophobia, and to which he gave the positive name of "lysophyton," and the belief of Klebs in the parasitic nature of the granular elements found around the blood-vessels near the sea, have appeared and disappeared within the last decade. The hasty statement of Pasteur that he had obtained from the saliva of a patient dying of rabies a peculiar germ, which, when he had cultivated it and inoculated the product, gave rise to a hitherto unknown disease, he was compelled to withdraw almost as soon as he had made it.*

The investigations of Benedikt, Coats, and Gowers are of the greatest interest in connection with this part of our subject. They are often spoken of as if their results were identical and conclusive, although, in fact, they are neither. Dr. Benedikt published his investigations in 1873, in Virchow's "Archiv." The text is accompanied with a plate, which leaves little room for misunderstanding the author's meaning. The lesions described and figured consist of a peri-vascular exudation or extravasation (or both) of red blood

* Nothing daunted by the experience of others, I observe that Dr. Paul Gütler reported to the Acad. des Sciences, of Paris, on the 11th of June, 1883, that he had found a special organism in the rhachial field of animals that had died of rables, and that the virus could be attenuated by means of cold. Another of the conclusions he announced at that time was that the disease is communicable from mother to fetus!
corpuscles, miliary spots of finely granular degeneration of the brain substance, "miliary abscesses," and melting down of effusions so as to make hyaline bodies alongside of the blood-vessels, often closing their lumen, while the vessels had a pigmented encasement (Pigmentthülle), made up of red blood corpuscles. These lesions were found in both dogs and men. Dr. Coats published his discoveries in the "Medico-Chirurgical Transactions" in 1878, accompanied also with plates. His investigations referred to tetanus and hydrophobia. He makes a point of the analogies between these two disorders, and, assuming a virus in hydrophobia, he argues backward that there is a poison circulating in the blood in tetanus. The lesions he describes in hydrophobia consist of a perivascular infiltration with white blood corpuscles.

In comparing these investigations it is to be noted that the lesions Coats found in tetanus correspond much more closely with those of Benedikt, found in hydrophobia, than do those the former found in his investigation of this latter disorder. Further, it is to be noted that he describes the perivascular infiltrate as consisting of white corpuscles, while Benedikt is clear in describing it as made up of red corpuscles. Finally, Coats does not consider (though most persons who refer to him speak as if he did) the lesions he found to be distinctive of hydrophobia, but simply evidence of irritation in the blood. Thus we see that these two investigators can not be regarded as confirming each other.

Now, the association of the name of Dr. Gowers (whose investigations are described and illustrated in the "Trans. of the Path. Soc. of London," vol. xxvii. 1877) with those of Benedikt and Coats, as having found lesions pathognomonic of hydrophobia, is equally unwarranted, for he distinctly stated, in answer to a question at the meeting where he demonstrated his specimens ("Launet," June 9, 1877, p. 840), that his investigation did not lead him to believe there was any special lesion in hydrophobia.

But, inconclusive and conflicting as the results of all these careful investigations have been, it might be easy to see how they might be taken for more than they are worth if it were not for the fact that they have been formally and categorically vitiated by the subsequent investigations of others. Thus, Middleton ("Journal of Anatomy and Physiology," 1881) has published the results of microscopic examinations in which he found perivascular aggregations of round cells in two cases of hydrophobia, corroborating some of the appearances described by Benedikt, but disagreeing with Coats and Kolesnikoff in essential points. But the most striking point of his publication lies in the fact that he found the same morbid appearances which were present in the cases of hydrophobia, in cases of puerperal hemorrhages, diabetes, fracture of the skull, erysipelas, head injury with hematomata, concussion of the brain with fracture of the spine, delirium tremens, peritonitis, tubercular meningitis, mental deficiency and excitement, hematomata, tetanus, and uraemia! His paper concludes with the distinct avowal that, "as regards the pathology of hydrophobia, it still remains true that nothing characteristic has been observed."

Another investigator, who has "gone over this ground and come to conclusions as destructive as those of Middle-ton, is Ivanoff, who says ("London Med. Record," March 15, 1883, from "Vratch," 1882, No. 15) that similar appearances to those observed by Benedikt, Gowers, and others are found in typhoid fever. One of the supposed characteristics, the transparent spaces, he says, was found by Popoff and Stephanoff in uraemia, and by Vinogradoff in intermittent fever, by Danillo in phosphorus poisoning, and, by himself and Dr. Czorkov in the brains of healthy dogs. They have no pathological character whatever.

But I need not detain you with further references to more or less famous investigations. I will only add that they all tend to confirm the opinion that as yet no gross or microscopical lesion has been discovered which can be regarded as pathognomonic of rabies or hydrophobia.

And now I must close. I have not said so much because it is any pleasanter or is likely to be any easier for me than for others to differ from the majority in the branch of science to which my life is given. It is with shrinking that I take a position which, if it is deemed worthy of notice, will be apt to excite opposition, perhaps condemnation. But I have now been engaged for nearly two years in a laborious study of the evidences upon which the general belief in regard to hydrophobia rests, and I have been gradually led to certain convictions different from those with which I started, and which I feel it my duty to make public.

One of these is that hydrophobia is not a specific, incalculable disease, derived from the bite of a similarly affected animal. Another is that, if we wish to have an accurate, scientific knowledge of what too often actually takes place, and is usually called hydrophobia, we must begin the study of it unprejudiced by the views heretofore generally entertained in regard to it, and with canons of criticism very different from those heretofore deemed sufficient.

I know that these convictions are not novel, and that they have been stated and defended with arguments before. I know, too, that they have heretofore failed to secure the assent of the greatest men who in every generation have adorned the profession of medicine. None the less, however, do I believe them to be true, and that the time will come when they will not be—as they have been in the past—characterized as too absurd to be discussed, or decrying as too dangerous to be tolerated.

But, however that may be, a sense of duty compels me to join myself to the small minority, whom I think to be on the right side of the question, for truth's sake. Further, in this matter the interests of science are, in an urgent sense, the interests of humanity. For this reason one who feels strongly must speak boldly. This, then, is my apology to those who may think I have erred in opposing the opinions of so many men deservedly honored and respected in our profession.

The "British Medical Journal" states that its weekly issue amounts to eleven thousand six hundred and fifty copies—a circulation, it asserts, about equal to the combined circulation of all the other weekly medical journals published in England. As the journal gives the number of members of the British Medical Association as ten thousand and fifty, to each of whom a copy is furnished, it follows that its circulation among non-members, including the exchange-list, amounts to only sixteen hundred.
BRAIN EXHAUSTION,*
AND ITS TREATMENT.
BY J. LEONARD CORNING, M.D.,
NEW YORK.

Mr. President and Gentlemen: The subject which I have selected for the discussion of your honorable body this evening is one which, by reason of its vast influence upon human affairs, is eminently worthy of scientific attention. Side by side with the progressive intellection of the century there have accumulated a host of clinical data, which point to a progressive decrepitude in the effectiveness of the thought mechanism itself. With the various advances in the mechanical facilities which place the individual in more complete harmony with extraneous conditions, it is a melancholy fact that a concomitant dissonance in the mental economy of the individual himself has become quite as characteristic a symptom of the progress of civilization as the advances in the mechanical arts or the exact sciences.

Therefore, in spite of the conquests over external nature, there is very much still to be learned concerning that thought mechanism the progressive manifestations of which have given us the astonishing control over the external world which is so characteristic a feature of the age.

Whereas the great question among individuals and nations has been, and must of necessity always continue to be, how to make surrounding nature subservient to the ends of organic life, there is yet another problem, which would appear to be the direct outgrowth of the heated competition of modern life, and which demands that, in the struggle for existence, the individual shall not only harmonize with his environment, but shall also be in accord with himself—shall preserve his physiological integrity in spite of the storm without. Among muscle-workers the question is one involving the normal assimilation and the conversion of forces into heat and mechanical labor. To the brain-worker the problem involves, in a modified degree, not only all that is contained in the foregoing, but, in addition, the whole question of mental economics.

We know of an inadequacy of the functional capacity of the motor apparatus dependent upon malnutrition of the muscle itself. We are also cognizant of a similar state of things affecting the organ of thought. It is of this impairment—this exhaustion of the functional capacity of the thought mechanism—that I would speak this evening.

Under the designation cerebral exhaustion I propose to consider a group of clinical phenomena, the chief feature of which is a morbid limitation of the ratiocinatory capacity of the individual consequent upon functional brain disease.

The manifestations of cerebral exhaustion are chiefly comprised under the following headings:

**Psychical Symptoms.**

3. Derangements of Memory.

5. Evanescent Mental Confusion.
7. Lack of Mental Concentrative.

**Physical Symptoms.**

8. Ocular Symptoms.
11. Local Head Pains.

**Secondary Symptoms, sometimes consecutive to or accompanying the Primary Exhaustion.**

14. Lachrymose Condition in the Male (wrongly designated Hysterical).
15. Morbid Sexual Manifestations.

It will be more expedient to discuss these symptoms, as far as possible, in the clinical order of their occurrence rather than to follow the purely mechanical subdivision just indicated.

First, as to the more prominent characteristics of the disorder. The first symptom often noted in cases of cerebral exhaustion is great restlessness during the day and more or less wakefulness at night. During the early morning hours there is often present a marked degree of drowsiness, and the persons thus afflicted frequently complain that they do not awake till midday. Soon the disturbance becomes greater; pains are felt in the regions of the vertex or above the supraciliary arches. These pains are frequently produced by the most trivial mental exertion. I am at present attending a gentleman who, after reading the newspaper for only five or six minutes, is attacked by a most intolerable vertical pain. Sometimes the pains are occipital, and then the application of the faradical current will often suffice to dissipate the symptoms.

In cases of unilateral or vertical headache, however, the problem is not so simple, the disagreeable symptoms often requiring more or less protracted treatment for their dissipation. The head pains are soon followed by mental phenomena of considerable intensity. The afflicted person complains of great mental lassitude, often bordering on absolute prostration. Even the slightest mental exertion is painful, and soon difficulty is experienced in performing even those semi-automatic mental operations which are incident to every-day life. Disorders of memory are among the most frequent symptoms. Sometimes the memory for both past and recent events is impaired; but I have remarked in very many instances that, while early occurrences are recalled with sufficient facility and accuracy, recent events make but slight impression, the individual being sometimes unable to tell chronologically what has occupied his attention even during the past few days. Familiar names and numbers are forgotten with particular readiness. When the disorder has continued for a considerable length of time, the will is seen to be impaired—so much so, in fact, that even the most trivial voluntary actions are a source of discomfort. To
CORNING: BRAIN EXHAUSTION AND ITS TREATMENT.

Dec. 29, 1888.

this condition of volition impairment is added a high degree of morbid irritability. Small disappointments are magnified a thousandfold, and those occurrences which under normal conditions would be deemed trivial assume overwhelming proportions. Frequent outbursts of uncontrollable anger, upon the slightest provocation, are among the most characteristic phenomena observed at this time, and are followed by more or less depression.

Among the most striking physical symptoms which point to the derangements in the cerebral economy are the disorders of the vaso-motor system.

When even slightly irritated or excited, the face becomes livid, whereas feet and hands are at the same time often cool to the touch. If now the radial pulse be examined, it will frequently be found to be quick and thready, whereas when the finger is placed upon the carotid or temporal artery the pulsation is found to be unusually strong. There is often present in these cases a tendency to abnormal cardiac action, palpitations being among the very frequent accidents. Hyperemia is, however, by no means always a constant factor. On the contrary, the condition of mental exhaustion is in a very large number of instances found in conjunction with very considerable general or local anaemia, or both. Under these circumstances the two conditions of cerebral hyperemia and anaemia very frequently alternate with each other; and it is perfectly clear that, according to whether the subject is seen during a period of cerebral plenorrh or anaemia, will be the diagnosis of the vascular condition. This circumstance has given rise, it would seem, to erroneous interpretations in many instances. These vascular derangements, though of secondary origin, being the direct outgrowth of an irritation of the protoplasm of the cells concerned in the evolution of mind and transmitted thence to the vaso-motor apparatus in the medulla by channels, which anatomy and physiology have not as yet satisfactorily demonstrated, are of the utmost importance on account of the irritation which they in their turn exercise upon the already irritated cortical area. Consequently they deserve especial attention in any consistent plan of therapy, and it will, therefore, not be a matter of surprise that a certain degree of prominence has been assigned to their treatment. In a recent monograph I have detailed at some length the experimental researches of myself and others concerning the relation of the cerebral circulation to brain function. Viewed in the light of those inductive researches which I have only time to briefly refer to on the present occasion, the importance ascribed to these circulatory anomalies will be perfectly comprehensible. Very noteworthy are the ocular appearances in the early as well as in the more advanced periods of the disease. Particularly characteristic is a dead and "bottomless" aspect, which, though hard to describe, when once seen is never forgotten.

Where the vascular derangements were more or less unilateral, I have sometimes remarked an unevenness of the pupil, as well as local spasms in the adductor pollicis and other small muscles of the hand. These latter symptoms, however, are comparatively infrequent. Tinnitus is not seldom met with, especially at night. When the disease has continued for a considerable length of time the condition of depression, alternating with outbursts of anger, becomes more and more pronounced until the subject is reduced to a deplorable state—often bordering on suicide. Friends, society, and even solitude become subjects of aversion and apprehension, the morbid dread often assuming fantastic and unexpected forms. For my own part, I have found these manifestations of morbid fear so manifold that specific designations have appeared to me superfluous, though others have made attempts in this direction. During the hours of morbid wakefulness hallucinations may occur, and, when this is the case, the mental condition of the patient may be considered more or less critical, unless energetic treatment should cause an abatement of the grave symptoms.

Before entering upon the discussion of what has appeared to me to be the most effective method of treatment to be pursued under the clinical circumstances, which I have just sought to describe chronologically, as far as possible, one word in regard to the causation of the above state of mental insufficiency. As predisposing factors may be mentioned: 1. That form of diathesis known as nervous, in which, although the temporary effectiveness of both the motor and physical apparatus is great, there is at the same time very little capacity for husbanding reserve energy. 2. Certain geographical peculiarities, and atmospheric conditions associated with diminished pressure and other factors of which we are still ignorant. 3. Occupations necessitating an abnormal amount of mental exertion. 4. The extreme subdivisions of labor, both mental and physical, incident to modern specialization, necessitating morbid concentration and excluding the rest formerly derived from employments requiring more general acquisition and a greater field of activity. Exciting causes are: 1. Extreme mental worry, accompanied by excessive mental exertion. 2. Constitutional drain through excesses—particularly sexual. 3. Malnutrition, general anaemia, and, 4, menstrual derangements. 5. Derangements of sleep, involving insufficient repair of the cortical cells concerned in intellution, and eventually resulting in the predominance of the processes of disintegration over those of integration in the central nervous system. 6. Certain organic diseases involving excessive waste, more particularly renal troubles, when accompanied by any considerable output of mental energy, may result in cerebral exhaustion. 7. Spasmodie, unsystematic, desultory methods of intellution. 8. Mental shock: Disappointment, profound grief, pecuniary losses; in a word, all those accidents which, acting with more than ordi-
comprising not only very considerable secondary vaso-motor anomalies, but, what is of the very first importance, insufficiency in the nutrition of the cell itself.

Admitting the foregoing to be the proper pathological interpretation of the morbid symptomatic phenomena, I know of but one rational system of therapeutics to be adopted in these cases; in a word, the problem presented for solution is how to again replenish the exhausted brain resources, and at the same time to improve the deteriorated mechanism of supply. In other words, the treatment must be addressed not only to the regulation of the morbid circulatory phenomena, but also to the stimulation and eventual restoration of the energy of the cell itself. The great factor in the successful treatment of this class of cases is rest—perfect, undisturbed tranquillity of the thinking apparatus—not the limited amount of rest suited to the healthy brain, but a quantity greater in proportion to the degree of morbid deterioration. By prolonged sleep it is possible for the ganglia to hoard up an amount of energy proportionate to the duration and profundity of the sleep itself, or, in other words, in the ratio of the reduction of the daily output of brain energy. Thus by slow degrees the proper correlation between integration and disintegration may be re-established. It is useless, however, to hope for any permanent results at once, for, when the perverted nutritive conditions have once become established, nothing short of prolonged rest can by any possibility result in the re-establishment of the normal nutritive processes of the cell economy.

The practical problem of cerebral rest I have sought to systematize as far as possible; but in communications on this subject have not forgotten to exhibit the many-sided aspect of the question. Indeed, it is sufficiently clear that the solution of this question is not to be compassed by one idea; there are no specifics here. What is required, however, is a comprehensive, practical, consistent plan of treatment—one based on the physiological and clinical exigencies. Where the function of sleep is affected, as it is in the majority of cases, it is impossible to increase at once the amount of rest to a sufficient extent to meet the demands of the morbid cerebral condition. Nevertheless, by gradually increasing the duration of the sleeping period, it eventually becomes possible to afford the patient an amount of rest sufficient to neutralize by slow degrees the condition of irritation and exhaustion. The bromides should be given during the day in cumulative doses, in order to allay the condition of irritability, and to cause a progressive decline in the mental manifestations as the hour for complete repose approaches. There should be no hesitation in employing sedatives, but always with the understanding that their use is only a measure of temporary expediency. Although I have found that in such cases permanent good is only to be obtained through the agency of protracted rest, a persistent course of tonic treatment should be undertaken as well. Thus, the fluid extract of cocca, taken with claret or Burgundy, has an immediately stimulating effect in those cases. In cases of general anemia, strychnine, iron, and the phosphates may be given. The most difficult class of cases to manage is that in which there is present some stomatogenic weakness precluding the possibility of any considerable medication, and necessitating a more or less protracted discontinuance of treatment from time to time. Phosphorus is a remedy which, in these derangements, often yields most excellent results; and although opinion differs as to whether the amount of phosphorus exerted is increased or not by an exercise of the intellectual faculties, the fact still remains that excellent therapeutic results are obtained from the employment of this remedy.

A systematic feeding is another factor of paramount importance in the treatment of these cases; without it the good results obtainable by absolute rest are greatly lessened.

In closing these very general remarks, I can not refrain from adding a word respecting the method by which I seek to practically carry out the above principles of treatment, namely: 1, Cerebral rest; 2, increased general and cerebral nutrition; 3, elimination of psychical irritation.

The subject is secluded in a darkened room from ten to fifteen hours at a time, according to the amount of sleep which it is desired shall be had during the twenty-four hours. The amount of sleep is progressively increased by habit, moderate medication, and hydro-therapy, and no attempt is made to produce a sudden state of stupor by the reckless use of sedatives. When the patient awakes, as is usually the case, two or even three times during the hours set apart for rest, nourishment is administered, but always in a fluid and easily digested form. Where difficulty is experienced in again falling asleep, resort is had in the beginning to limited medication. The few hours of wakefulness are devoted exclusively to some form of amusement—reading, writing, and even the mildest forms of mental concentration being absolutely prohibited. This, in brief, is the method from which I have already seen most happy results, and from the employment of which I hope and believe much good will in future be derived. It is hardly necessary to say that the problem of cerebral rest is essentially different and presents many more difficulties than spinal rest. To give repose to the motor cells of the cord is comparatively an easy problem, and one which only exacts a permanent fixation of the motor apparatus for its solution, the consciousness or unconsciousness of the individual being only a matter of secondary importance. Rest, however, for those cells, the function of which is the evolution of mind, can only be obtained by a prolonged period of absolute unconsciousness; and this, as a matter of course, will often tax the patience and resources of the physician to the utmost. Perseverance and the utilization of the principle of habit will usually, however, render essential assistance.

A CASE OF BILATERAL SEPARATION OF THE EXTENSOR TENDONS.
FROM THE PATELLAR INSERTION.

By V. P. Gibney, M. D.

A man, fifty-eight years of age, came under observation in the Out-door Department of the Hospital for the Ruptured and Crippled, October 18, 1883. Ten years before, he fell, detaching the quadriceps extensor, on the right side, from the patella. Six years later the same accident occurred on the left side.
During the past winter the right knee became the seat of arthritis, was treated in a hospital, and, from the account he gives, there was profuse suppuration.

It seems the knee was opened and washed out several times and the wound then healed.

The peculiarities of his gait on the date of his first appearance at the dispensary was interesting, and, on examination, the quadrieps extensors on either side seemed to be entirely gone, so that the finger could be thrust behind the superior border of the patellae and rest well in the inter-condyloid notches.

While on a level surface he walked, fairly well, and, curiously enough, he has very few falls.

If the legs are flexed, he can not extend them at all. The right one can be extended to 170°, and flexed to 70°, passively. There is much grating on passive motion, and the patella is quite immovable. There are several clicks about the knee.

The left knee can be flexed and extended passively over normal arcs.

The case presents no further points of interest, and is presented more as a curiosity and an illustration of how well the man can walk without these tendons. The result of the arthritis on the right side is excellent, and another question might arise as to the benefit derived from the absence of the tendons, thus relieving the joint from the patellar pressure.

A CASE OF FOREIGN BODY IN THE RECTUM.

By W. T. OPPENHEIMER, M.D.,
HOUSE SURGEON, BELLEVUE HOSPITAL.

On October 29, 1883, J. C., aged eighteen, was admitted to Bellevue Hospital on account of great pain in his rectum, the pain being intensified whenever he attempted to sit down.

He had the impression that on the previous night, while he was intoxicated, an apple had been forced into the bowel by some of his companions.

An examination with the finger revealed the presence of a globular-shaped body, occupying the rectum about two inches above the external sphincter ani.

Every attempt to pass the finger above the foreign body only resulted in pushing it farther into the gut.

The patient was placed in Sims's position, the blades of a pair of lithotomy forceps were easily introduced, the foreign body grasped, and, by a combination of traction, lateral and rotary movements, it was, with difficulty, removed. It proved to be a large, very hard green pear, measuring three and one half inches by two, with its stem still attached.

Some hemorrhage attended the operation, and the sphincter was found to be temporarily paralyzed in consequence of the stretching to which it had been subjected.

Patient left the hospital the next day, apparently doing well.

It is generally admitted that, when a conical-shaped body is placed in the rectum, its natural tendency is to take that direction in which there is the least resistance, and so may pass into the colon and lead to a fatal result by causing ulceration, with perforation of the bowel.

The present case is chiefly interesting as a matter of record.

THE NEW YORK EYE AND EAR INFIRMARY has received a gift of $3,000 from Mr. Royal Phelps, its late president, to whom it is indebted for many years of wise and prudent management.
influence of the tuberculous deposit which existed. Dr. Edison, Dr. Allbut, and Dr. Chaston, under whose care these patients were, believe that it is better to do the operation under the antiseptic spray, in order to guard against septic matter entering the pleural cavity when this is first opened. This precaution will be omitted in the present case for the reason that a canula and trocar will be used to which a rubber tube is attached leading underneath an antiseptic solution. It is not thought best to empty the cavity completely at the first sitting. The nurse of treatment also has an American advocate in Dr. Wilson, of Philadelphia. He makes the puncture with the trocar and canula, and afterward inserts a soft rubber catheter through the canula and withdraws the latter. The catheter is retained in position by means of silk thread and strips of adhesive plaster. The cavity is washed by means of a ball syringe and soft rubber tubing, and the solution employed is one of bichloride of mercury, beginning with 1 part to 15,000 and gradually increasing the strength to 1 in 5,000. At the first sitting the amount injected does not exceed one fourth the amount of pus withdrawn. As the cavity contracts, the intervals between the washings are prolonged. During the intervals an oakum pad is applied. When the discharge becomes serous and does not exceed two drachms the tube is withdrawn, and the sinus is permitted to heal. The same plan is pursued when spontaneous opening has taken place.

It has been found better to make but a single opening and employ only one drainage-tube—only exceptionally are two openings necessary. The cases do not always proceed most satisfactorily even after the amount of the discharge has been reduced to one or two ounces. When a standstill is reached, you may try all sorts of antiseptic and stimulant washings, or make a second opening, with through-drainage, and still fail to effect a cure. Perhaps we may be compelled, by the strong tendency on the part of the wound to close by approximation of the ribs, to enlarge the opening by taking out a piece of one or more of the ribs. I remember an instance in which, even after this, a patient went for eight years with an opening in the chest discharging more or less pus, and subjected now and then to inflammatory exacerbations. While at Kiel, last spring, I saw an example of what surgery can do for some of the worst cases of this sort. The pleural walls continued in this case to discharge a copious amount of pus, just as the walls of a bone cavity sometimes do after the removal of a sequestrum, and will not heal from a similar cause. In the case alluded to, Neuber raised a skin flap from the ribs, took out a piece of four or five of the ribs, with the thickened pleura, larger than the palm of the hand, exposed the pulmonary surface which was giving rise to the persistent discharge, scraped it, and laid the raw skin down upon it, which adhered, and closed the secreting pleural cavity. This operation has also been repeated elsewhere satisfactorily, and without distortion of the spine. Acting on the statement of the house surgeon that he had observed dullness in the recumbent posture higher up than the spot chosen for a ny opening, in the sixth space, on a line with the back of the aorta, I have introduced the trocar and got a "dry tap." The mistake may lead to fresh inflammation, but it will not stand in the way of making a puncture more posteriorly; and I will do now what I should have done at first, and what I hope you will do—introduce the hypodermic needle, get pus, and then push in the trocar and make the incision as may be determined on. Having got this proof, I have removed a quantity of pus, which, as it escapes, gives off a very offensive odor. The further dressing will be conducted according to the plan before mentioned. [Note.—The patient died forty-eight hours later, and the autopsy showed limited empyema from gangrene of the lung. No inflammation had followed the first puncture.]

Case II.—The case which I am now about to bring before you is one of stricture of the rectum occurring in a colored woman, thirty-six years of age, unmarried, who has never borne children. I asked especially with regard to this point, because prolonged pressure of the child's head on the bowel has been considered one of the common causes of stricture of the rectum. Her rectal trouble began four years ago, when she was told that she had the piles. There was at first a mucous discharge, mingled occasionally with pus, also a condition of constipation which grew more and more severe, and finally she was able to obtain relief only by the use of purgative medicines. The local pain has been slight. Cancer can be excluded mainly by the absence of severe pain, as well as by the smooth feeling of the stricture itself. She has never suffered from sickness, so that cause may be eliminated. Though it is a veritable one, formerly this was doubted. There is another cause which might exist in the present case—namely, chancroidal ulceration. This poison might be introduced directly, or it might find its way to the rectum from the vagina. I have seen a number of such cases, and in one instance the chancroidal ulceration of the rectum had been of three years' duration. It was finally cured by the actual cautery. This patient had a bubo eight years ago. You will see, therefore, that there is a gap of four years between the time of the occurrence of the bubo and the rectal symptoms—too much, perhaps, for us to put them together as cause and effect. As I examine the patient, I find that the stricture has only a slight amount of induration, that it is situated about two inches from the anus, and that it will admit only the little finger. Above it I can feel smooth but somewhat thickened mucous membrane. It is, therefore, a simple stricture of inflammatory nature, and the cause of the inflammation is uncertain.

The operation which I propose to perform is a modification of the one originally introduced by Verneuil. This surgeon carried the wire or chain of an erasure from a point near the coccyx into the gut above the stricture, even as high as four inches from the anus, and cut through the stricture and all intervening tissue. This operation was modified by the English surgeons by making the division of all the tissues complete with the knife, from the bowel down to the coccyx, or even the sacrum, cutting the sphincter ani completely. I have performed this latter operation nine times, and in only one case did any considerable hemorrhage take place, and in that case it was promptly arrested by plugging. Of the nine patients, two died from septic processes contracted in the hospital; the others did well. But there is one serious objection to the operation, namely, that the sphincter, which is divided to the coccyx, regains its power very slowly indeed. Not that incontinence results, but that a suppurating surface is left, rendering the patient very uncomfortable. This may perhaps be remedied by a plastic operation, but I have not yet had an opportunity to try it. Instead of performing either of these operations, I propose to-day, therefore, to stretch the sphincter thoroughly, divide the stricture tissue posteriorly, and, in order to avoid the risk of burrowing about the rectum, which such incisions generally cause, make a complete artificial fistula by thrusting my scapula from outside the sphincter through into the wound, and through the tract introduce a draining-tube, apply an iodiform dressing to the internal incision and over the anus, keeping the bowel quiet for several days, and see if by this means the stricture may not be relieved.

The stricture is now divided, and I am able to pass three fingers, and even four, readily into the rectum, while before I could only introduce the tip of the little finger. The operation has been completed after the manner just described. [Note.—No inflammatory resorption having occurred, the tube was withdrawn after four days. The bovels moved only twice in ten
days; nothing escaped through the track of the drainage-tube, and it has apparently closed.)

Case III.—The third case is one of tight stenosis of the urethra just anterior to the triangular ligament, the origin of the trouble being in a gonorrhoea contracted seventeen years ago. Complete retention of urine has never occurred. We see so many of these cases that I will not dwell specially on this one, but will simply state that the stenosis will be divided by a Maisonneuve’s uretrotome, cutting upward so as to make the urethra admit a No. 32 sound. The only difference from the other cases is, that the urethra will be drawn off at the close of the operation, and the bladder washed out with a 1-to-5,000 solution of corrosive sublimate. The urethra will be flushed with the same solution as the catheter is withdrawn. A long soluble bougie of one grain of iodoform, or an injection of two grains of iodoform to the ounce of oil, will be introduced into the urethra once or twice a day. These precautions will be taken to avoid urethral fever, as considerable difficulty was experienced in the introduction of the sound after the stenosis was divided, and it was feared that a sharper reaction would occur if altered urine were allowed to flow over a somewhat bruised incision.

Book Notices.

This small hand-book is the first in a series of Manuals for Students of Medicine in course of issue by the same publishers. By cutting down the margins, setting the type closely, and the use of thin paper, the book has been kept within small pocket size, without employing type so fine as to be at all difficult to read. This particular volume, for example, contains 347 pages of text and woodcuts, besides a full index. The text is well arranged, and gives a brief but sufficiently full account of most of the recent researches of importance. The genesis of the red and white blood corpuscles, for example, is described without omission of any important discovery among the many which have lately crowded this much-studied field, and covers a wider range than that embraced in any text-book published in English. There is a good deal of comparative embryology, partly introduced by way of illustration, but very largely too as the basis of deductions in human histology, the author not appearing to hesitate to draw positive histological conclusions from one order or class of animals to another. The one hundred and eighty-one woodcuts are uncommonly well drawn and printed, and are also remarkably well selected for their purpose of illustrating and explaining the text. Besides the original drawings (a considerable proportion of the whole number) there are judicious selections from Ghose’s “Atlas of Histology,” Burdon Sanderson’s “Handbook for the Physiological Laboratory,” Henle, Gerlach, E. Fischer, W. Fleming, Key, Retains, Wadley, Heldenbain, Kolliker, etc. The excellence of the cuts is due to the skill of Mr. Charles Bergetu, F. L. S., who has drawn them upon the wood with artistic delicacy as well as technical accuracy.

We have here, in short, a compendium of the wide field of human histology coming well up to the researches of the present day, and, considering the smallness of its bulk, of truly remarkable fulness. Many of the faults of execution that we notice are such as may reasonably be expected to be amended in future editions. Such are occasional slips in proof-reading and rather too frequent obscurities of statement; as when the writer speaks of “continuous masses of epithelial cells,” or sets down such a sentence as the following: “They (the Haversian canals) are surrounded by numbers of concentric lamellae, with the bare corpuscles between them, and this is a system of concentric lamellae” (p. 53). Sometimes, from insufficient revision, the description of a borrowed cut is allowed to retain terms not explained in the text—an omission likely to perplex the medical students for whom the manual is particularly intended. But a far more serious defect, perhaps the most serious in the book, is the omission of all indication of the number of diameters by which the tissues represented, often very highly magnified, are enlarged. When, as frequently happens, contiguous cuts represent objects viewed under very different amplifications, much of the value of the illustrations is lost to the student.

It is not, to be sure, the custom to burden elementary hand-books with references or foot-notes, but when, as in this case, the pages are crowded with the mention of authorities little known even by name to the general reader, more advanced students will be very glad to accept, in future editions, a small increase in bulk in return for more exact citations of authorities.

On the whole, the “Elements of Histology” bears out well the modest statement of its preface, that “the work contains a good deal that will be acceptable to the advanced student as well as to the beginner,” and it may safely be expected to meet with a large sale.

BOOKS AND PAMPHLETS RECEIVED.

Relation of Eye to Spinal Diseases. By A. Friedenwald, M. D., etc. [Reprint from the “Transactions of the Medical and Chirurgical Faculty of Maryland.”]

The Electro-Osteotome. A New Instrument for the Performance of the Operation of Osteotomy. By Dr. Milton Josiah Roberts, Professor of Orthopedic Surgery and Mechanical Therapeutics in the New York Post-graduate Medical School, etc. [Reprint from the “Medical Record.”]

Some Recent Progress in Diseases of the Nervous System. By Talbot Jones, M. D., St. Paul. [Reprint from the “Alumni and Neurologist.”]

The Antipyretic Treatment of Typhoid Fever. By G. C. Smythe, M. D., Professor of Principles and Practice of Medicine, Central College of Physicians and Surgeons, Indianapolis. [Reprint from the “Cincinnati Lancet and Clinic.”]

A Contribution to the Clinical Study of Typhlitis and Peri-typhlitis. By William Pepper, M. D., LL. D., Provost and Professor of Clinical Medicine in the University of Pennsylvania. [Reprint from the “Transactions of the Medical Society of the State of Pennsylvania.”]

New Operation for Rupture of the Perineum through the Sphincter. By J. Collins Warren, M. D., Assistant Professor in Surgery in Harvard University, etc. [Reprint from the “Gynecological Transactions.”]
NEW YORK, SATURDAY, DEC. 29, 1883.

THE ABUSE OF MEDICAL CHARITIES.

Attention has often been drawn to the imposition practiced upon charitable institutions, and especially upon their medical officers, by patients who are quite able to pay ordinary medical fees, and to provide themselves with the drugs and appliances usually needed by persons in their condition. There is only too good ground for believing that the abuse is becoming greater and greater every year. Perhaps the fact is fully realized only by the struggling practitioners who have not the advantage of a hospital or dispensary appointment, for it is on them that the burden falls. No one seriously denies it, however, but, alas, nobody seems to have both the will and the power to aid materially in remedying it, although it has been brought forward as a grievance before the medical profession, and laid before the governing boards of several of the institutions concerned. Everybody comprehends how street begging, from having been a thing almost unknown among us a few years ago, has come to be an established nuisance, but, as a community, we have not yet realized that any resident in this land of prosperity can possibly play the panther except as the result of dire necessity. To some extent, no doubt, the evil is fostered by the avidity with which "clinical material" is seized upon; and, to that extent, the profession has itself to blame. As regards the governing bodies of the hospitals and dispensaries, on the other hand, it can only be supposed that their failure to do anything toward the practical suppression of the evil is the result of a lack of thorough comprehension on their part of its extent and its importance.

A precedent is often of much force under such circumstances, and it is satisfactory to learn that the London Hospital has furnished one in the shape of a notice recently issued for the information of its governors and its out-patients. It may take some time for a London example of this sort to be followed in New York, especially as it is not usual here for out-patients to need a governor’s certificate to enable them to get treatment at a hospital or dispensary; but the step taken can scarcely fail to have its influence in the end. The notice in question is to the effect that, on and after January 1, 1884, a waiting-hall inspector will be employed to ascertain whether any applicants presenting governors’ letters are able to pay consulting physicians’ or surgeons’ fees, or, if their cases are not urgent, those of local practitioners; or should be referred to recognized provident institutions; or, being in receipt of parish relief, should be required to attend at poor-law dispensaries. To guard against unnecessary duration of a patient’s attendance, a governor’s letter will not entitle him to more than one attendance, except by the decision of the medical officer; and the latter is not at liberty to continue the ticket in force unless, in his opinion, further hospital treatment is necessary. New tickets presented by patients who have been set down as not in need of further treatment will be canceled at once unless the ailment for which they apply is a new one. Untruthful replies to inquiries will work a forfeiture of the ticket.

It is justly suggested that these arrangements, while so limiting the number of patients in attendance as to enable the medical officers to give more of their time to those who really need it, will enhance the value of tickets to governors and subscribers, as well as to those patients who actually require and deserve hospital treatment. The latter consideration has full as much force here as in London, and it is earnestly to be hoped that before long the fact will be recognized by the governing boards of our hospitals.

PHTHISISPHOBIA.

In view of the eagerness with which men grasp at a positive theory, in place of clinging to the anchor of doubt, and bearing in mind how well-nigh unavoidable the temptation is to view as actual facts whatever the theory seems logically to lead to, it was not altogether an unhappy conceit on the part of Dr. Wilson Fox, of London, when he lately deprecated the prevalence of what he termed "phthisophobia" in modern society. There can be little doubt that a morbid dread of this sort would be much more likely to seize upon the community if it should come to be generally admitted that accidental inoculation with non-specific matter of various sorts was capable of giving rise to tuberculosis. In the past there has been some danger that such a conclusion would be drawn, chiefly as the result of certain experiments which, while their first effect was to throw doubt on Villemin’s idea of the specific and inoculable nature of consumption, seemed to establish the possibility and the danger of setting up a tuberculous process by contaminations of the blood akin to those which must necessarily take place every now and then.

To admit that any one of a great variety of indifferent substances may, on gaining entrance into the circulation, give rise to tuberculosis would clearly be to pave the way to a widespread and almost ineradicable "phthisophobia" with a certainty attainable by few other means. To wage war against the bacillus, with whatever subtlety observation may compel us to invest it, is to fight a single enemy; to make sure that all manner of foreign material is at every moment barred out from the circulation is impossible. It is comforting to find, therefore, that the experiments to which we have alluded have lately been repeated with results which seem to show that the methods by which they were first carried out must have been faulty in some respect. At a recent meeting of the Pathological Society of London, Dr. Dawson Williams gave an account of his repetition of the old experiments, and cited others of like purport by Mr. Watson Cheyne, and it was on this occasion that Dr. Fox gave expression to the sentiment we have indicated. It was at the request of the latter, indeed, that the experiments were undertaken.
According to the account given in the "British Medical Journal," great pains were taken to guard against tuberculous contamination of the fluids and the instruments used, but no antiseptics were employed. The experiments included the use of putrid fluids and setons, and in no instance did any tubercular or purulent process follow. Dr. Williams thinks the evidence is now very strong in favor of the specific theory of tuberculosis, and in favor of the doctrine that the bacillus plays an essential part in the process. Dr. Fox frankly abandoned his former interpretation of the old experiments, and acknowledged that we were now reduced to Villiomin's original position. This position, it will be remembered, was, that tuberculosis is specific and inoculable—a conclusion that was purely inductive in the first instance, but supported by experimental researches which now seem to have had restored to them the positive significance of which they had long stood deprived.

But we must not lose sight of the consideration that the experiments which at first seemed to rob them of this significance were never held up as examples of infection in the true sense of the word. They were stumbling-blocks only in so far as they appeared to show what might happen when obviously no specific infection had taken place. Such being the case, in the spirit of Dr. Fox's caution against hastily drawing conclusions from pathological experiments, a number of repetitions may yet be necessary to overthrow the conclusions to which the old experiments led, for it may turn out that accidental contamination of the instruments and the solutions used is not enough to account for the diversity of results.

THE CONCURRENT ACTION OF ALCOHOL AND CHLOROFORM.

Several years ago the French physiologist, M. R. Dubois, published some elaborate investigations, undertaken under the direction of M. Laborde, to determine the influence of alcohol in modifying the action of chloroform on the system. The precision in anesthesia that has now been made practicable by the experiments of M. Bert has seemed to M. Dubois to call for a repetition of his former study of the matter. Accordingly, he has entered upon the inquiry anew, and publishes the first installment of the results—relating to acute alcoholism only—in a recent number of the "Progrès médical." The investigation as a whole has to deal with three different forms of alcoholism—the acute, the chronic, and the recurrent. The last-mentioned, termed alcoolisme en retrait, is defined as the particular state observed when an habitual drinker is suddenly deprived of the allowance of spirit which ordinarily keeps him up to what may be called a false normal condition. This form, he points out, should not be confounded with chronic alcoholism, in which the patient is continually taking his accustomed quantity of alcohol.

Confining himself for the present to acute alcoholism, and referring to experiments on dogs acutely poisoned with alcohol, M. Dubois concludes, as the result of the use of a ten-per-cent. admixture of chloroform with air: 1. That the rapidity of anesthesia is increased during acute alcoholism. 2. That the animal's vital resistance is diminished in duration. 3. That, consequently, the proportion of chloroform in the anesthetic mixture may be lowered. 4. That the quantity of the mixture as a whole that is necessary should enter into the respiratory passages, to produce either anesthesia or death, is smaller than in the normal condition. 5. That, quite as in animals that have not been subjected to alcoholic intoxication, the reduction of temperature is in direct proportion to the duration of the animal's resistance.

As regards the character of the phenomena that show themselves, it is almost identical in animals that have been alcoholized and in those that have not; and this fact constitutes a well-marked difference between acute alcoholism and the other forms mentioned. In the acute form, M. Dubois remarks, the alcohol would be acting as an adjuvant to the chloroform, and what was gained in rapidity would be lost in resistance.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending December 25, 1883:

Yellow Fever is reported to have made its appearance in Rio de Janeiro, where, as the warm season is just beginning, its extensive prevalence is to be apprehended.

THE "ARCHIVES OF MEDICINE."—It is announced that with the December number this steller periodical closes its publication. It is unnecessary to call attention to the great worth of its contents during the few years of its existence; they have embraced many of the most important papers that have emanated from the profession in this country. Notwithstanding its discontinuance, the "Archives" will not soon pass out of the memory of the many who have delighted in its pages.

THE "ARCHIVES OF LARYNOLOGY."—It is understood that this journal also has now become a thing of the past. To it likewise we must accord the credit of having been a prominent and worthy exponent of an important element in American medicine.

THE HOSPITAL SATURDAY AND SUNDAY ASSOCIATION specially asks that contributions be made to the general fund, which is to be divided among the associated hospitals. Money may be sent to the general treasurer, Mr. Charles Lanier, at No. 26 Nassau Street, before January 13th.

The Lunatic Asylum on Ward's Island was last Friday the scene of an accident that might easily have proved very serious. The upper story of one of the wings took fire, and the fire had made such progress, when it was discovered, that the total destruction of the building was threatened, and the work of removing the patients hastily, and yet with the preservation of order, became a necessity. This was satisfactorily accomplished under the personal direction of the superintendent, Dr. Macdonald, to whom great credit is due.
The Paris Faculty of Medicine.—In our last issue we mentioned the probability that an agrégé would be designated to perform the duties of the chair of diseases of children pending the appointing of a successor to the late M. Parrot. In pursuance of that plan, M. Roudi has been chosen for the work.

The British Medical Association will hold its next annual meeting in Belfast, Ireland.

The Cauterity Lectures for 1884 will be delivered by Professor Bart G. Wilder, M. D., of Cornell University, at the hall of the Young Men’s Christian Association, corner of Twenty-third Street and Fourth Avenue, on the evenings of February 2, 4, and 6, 1884. The general subject will be “Methods of Studying the Brain.”

A Reception to Dr. M. Jonah Roberts, of New York, was given in Pittsburgh, Pa., on Thursday evening by Dr. William H. Duly, of Pittsburgh. Several of Dr. Roberts’s professional brethren in New York and Philadelphia, together with a large number of Pittsburgh physicians, were invited to be present.

A Libel Suit having been brought by a member of the medical faculty of the University of Michigan against a newspaper that had charged him with criminal relations with a lady who was his patient, $29,000 damages were awarded by the jury, and, the case having been appealed, the Supreme Court has affirmed the judgment. Such a charge against a physician is no light matter, and it is a pleasure to be able to record the result of the suit in this instance.

Letters to the Editor.

To the Editor of the New York Medical Journal:

Sir: My attention has been called to a letter in a late number of the “New York Medical Journal,” signed with the initials A. L. C., relating to the John Hancock Mutual Life Insurance Company of Boston, Mass. As the writer’s remarks might have a tendency to mislead, since he has written about a matter of which he is ignorant, I am constrained to answer him, in order that the correct facts may be known. The John Hancock Company, in addition to its regular business, adopted in 1879 the plan of industrial or prudential insurance, based upon a system which has been in most successful operation in England for the past thirty years. Without entering into the particulars of this method of life insurance, it will be simply necessary to state that prudential insurance is designed for the masses, who can not afford to insure their lives for large amounts, but who are enabled by the above plan to take out policies on their own lives and those of their children (within certain ages), for small amounts, by paying small weekly premiums, ranging from five to fifty cents. For all applicants, whether adults or children, the company requires a medical examination; but, as the weekly premiums are so small, it is impossible, as a matter of business, to pay the examiners more than the small fee of twenty-five cents, particularly as the examination of the children, who are usually seen in groups, amounts to but little more than an inspection. Although this fee is recognized as being small, yet at the same time it has been proved that there are certain compensations, apart from the actual sums paid for the examinations (these sums amounting in many cases to fifty, seventy-five, one hundred, one hundred and twenty-five, one hundred and fifty, and even as high as two hundred and sixty dollars, paid to single examiners for single months’ work), compensations growing out of the acquaintance formed, which in many instances has led to such an increase of private practice that examiners have resigned, since they were no longer able to attend to the duties of the company.

Our policy is to appoint as medical examiners in the prudential branch young men who may not be overburdened with practice, and to whom not only is any honest solution to their professional income acceptable, but also any practice derived from a class of persons who, I grant, do not belong to the upper ten thousand. Such a class of examiners we have always been able to find, who have performed their work skillfully and well, to their professional advantage.

Yours truly,

Frank Wells,
Medical Examiner, John Hancock Life Ins. Co.
Boston, December 6, 1883.

Proceedings of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

A called meeting was held December 21, 1883, S. O. Van der Piel, M. D., President, in the chair.

THE PREVENTION OF Puerperal Infection.—Dr. H. J. Garrigues read a paper with this title, the object of which was simply to lay before the profession the means by which he had succeeded in freeing the maternity wards at Charity Hospital of puerperal fever. He would leave out of consideration all theorizing regarding the nature of puerperal fever. Brief allusion was made to the history of antiseptics in obstetrics. Dr. Garrigues himself had so far adopted Listerism in midwifery practice during the past eight years as to make it a habit to wash his hands and instruments in a carbolic acid solution, to make vaginal injections twice daily during the first week after delivery, and to wash out the uterus, when indicated, either as a prophylactic or curative measure. He carried this plan with him to the Maternity Hospital, on becoming one of the visiting physicians. While this hospital had a special board of physicians, it was not an entirely separate institution, but a part of Charity Hospital, and everybody knew how great was the mortality usually among lying-in women in a general hospital. The following statistics for the Maternity Hospital were read:

While some of the deaths were attributable to diseases for which the hospital was not responsible, the great majority were the effect of hospitalism. During the first nine months of the present year the number of deliveries had been 343, with 30 deaths. During the first three months of this year, while the author was on duty, the number of deliveries was 108; the mortality, 11. Before a recent date it was the exception rather than the rule to see a perfectly normal lying-in period. During the six months from October 1, 1882, to March 1, 1883, when the author of the paper had been on duty last, there were 192 women delivered, 46 of whom, or almost 1 in 4, were seriously sick, 39 of inflammatory puerperal disease. When the author went
on duty, October 1st of the present year, the condition of the
hospital was at its worst, nine women having died during the
last month, and half a dozen sick puerperae being left over from
the preceding service, one of whom died a few days later. In
the mean time bichloride of mercury began to be praised in surgi-
cal and obstetrical practice, and he therefore made use of it in
the Maternity Hospital. But, not trusting entirely to the vir-
tue of a newly introduced drug, he adopted several other mea-
ures, all of which may have contributed somewhat to the excel-
ent results obtained.

The service was divided into two separate departments, one
for the sick puerperae, and the other for those who were doing
well. Rapid alternation in the use of the wards was secured.
The doors leading from the one to the other were locked, and
the chinks filled with tow and pasted over with paper, so as to
leave only an entrance from the open air. Doors leading to
water-closets were provided with springs, and the water-closet
windows were nailed open in such manner as to prevent their
being closed. When empty, the wards were thoroughly fumi-
gated with sulphur fumes. The windows were then left open
day and night; the floors and furniture were scrubbed with soap
and water and a solution of bichloride of mercury (1 to 1,000); 
the bed-clothes were changed, and fresh straw was put into
the ticks. In all the wards large demijohns were placed,
filled with the 1 to 1,000 bichloride solution, which was mixed
with equal parts of water at different temperatures for use
in washing the hands, making injections, etc. It was used
hot or lukewarm, according to the indications. When the pa-
ient was brought to the delivery room she was given a bath
and an enema, and the genitals, the buttocks, and the thighs
were washed carefully with a lukewarm solution of the bi-
chloride, 1 to 2,000. At least two quarts were injected into
the vagina by means of the fountain-syringe. The fountain-
syringe consisted of a glass bucket, a long rubber tube, a straight
glass tube for vaginal injections, and a curved one for intra-
uterine injections when needed. The latter tube was perforated
at the end, and there were eight perforations on the stem, near
the extremity. In cases of tedious labor the vaginal injection
was repeated every three hours. The rubber sheet covering the
delivery-bed was washed with the antiseptic solution just before
delivery. In order to limit the danger of infection by exami-
nation as much as possible, none of the nurses were allowed to
make examinations except the one in charge of the waiting
ward and the head nurse in the pavilion, and these were directed
to do so oftener than necessary to notify the doctors. The
latter were requested not to introduce the finger into the womb,
but to be satisfied with an abdominal examination and an ex-
amination of the part presenting at the os externum. At the
beginning of a labor, doctors and nurses washed their hands in
the solution. Besides, the hands were to be held in the solution
a minute or more each time before the genital organs were
touched. If the hands or instruments were to be introduced
into the womb, bichloride was used, with the bichloride of mer-
cury, 1 to 2,000. This was preferred to carbolized oil, as
the bichloride possessed antiseptic properties, which were
enhanced by the addition of the bichloride. When the head
appeared at the vulva, a piece of lint soaked in the bichloride
solution was applied, and kept there for the prevention of the
entrance of contaminated air into the vagina. After the expul-
sion of the child the genitals were kept covered with a similar
compress. The placenta was expressed, so as to avoid the in-
troduction of the fingers into the vagina. If in exceptional cases
they had to be introduced, the vagina was afterward washed out
with the antiseptic solution; otherwise not. On the same prin-
ciple, intra-uterine injections were employed only when the
hands or instruments were introduced into the womb, or after
the birth of a macerated child. He never allowed any part of
the placenta or membranes to remain in the womb; the intro-
duction of the entire hand into that organ gave rise to very little
danger compared to that of hemmorhage and septicemia, which
were liable to develop if any part of the afterbirth were left
behind. In such cases the intra-uterine injection was given
immediately after the removal of the secondaries, from two to
six quarts of a hot solution being employed. In case of symp-
toms arising during the lying-in period pointing to possible
affection of the uterus, a speculum was inserted, a careful ex-
amination of the vagina and cervix was made, and, if called for,
the uterine injection was given by passing the tube through the
speculum, while immediately after delivery it was introduced
between two fingers held in the cervical canal.

After the removal of the secondaries the patient was washed
with the antiseptic solution, and a piece of lint, six inches wide
and eight long, folded lengthwise so as to be three inches wide,
was placed over the vulva. Outside of that was placed a piece of
oiled muslin, nine inches long and four inches wide; over
that still came a large pad of oakum; and, finally, the whole
was fastened to the binder by a piece of muslin eighteen inches
square, folded together so as to form a kind of boat five inches
wide, and pinned in front and behind at each of its corners.
This dressing was renewed four times in the twenty-four hours.
At the same time the genitals were washed with the bichloride
solution. The floor of the ward was sprinkled four times a day
with the undiluted solution. In order to prevent infection
through visitors, the patient was not allowed to see any person
while in the pavilion unless death was imminent, when a min-
ister was admitted. The doctors and nurses were not allowed
to go into the general wards or into the dead-house.

The instruments were put into a five-per-cent, solution of
carbolic acid, the bichloride being injurious to metal. The pa-
ients sometimes complained of a little smarting from the bi-
chloride, and in one case it seemed to produce a slight eruption,
which was easily controlled by glycerin. In no case had there
been any general symptoms attributable to the mercury. The
dressings were continued so long as the patients were in the
convalescent ward. They were usually discharged between the
tenth and fifteenth days.

The result of the adoption of this plan of treatment had
been wonderful. As by magic, all trouble had disappeared.
Ninety-seven women had been delivered since its introduction,
and not only had none died, but there had scarcely been any
sickness among them. There had been no trace of diphtheritic
inflammation, by which they used to be persecuted. Where
they formerly had offensive odors, feverish and despairing pa-
ients, over-worked nurses, and despondent doctors, the air was
now pure, the patients looked well, their temperature was nor-
mal, the nurses were cheerful, and the doctors happy.

Bichloride of mercury had certain advantages over carbolic
acid: First, it was a much more reliable disinfectant; second,
it was not only free from odor, but it was also an excellent
deodorizer; third, it affected the skin of the nurse and accomplice
less; fourth, it was more economical.

In private practice he used the same treatment, substituting
cotton for oakum, using a rubber fountain-syringe or Davidson's
syringe, and changing the dressing only three times a day. For
the intra-uterine injections he used a tin tube, especially in
cases of abortion, in which it might be necessary to change the
curve somewhat, adapting the instrument to each particular case.

Dr. J. A. Murray gave the statistics of the Maternity Hos-
pital during his three months of service preceding that of Dr.
Garrigues, and said that out of 90 patients delivered 14 died,
8 from conditions directly traceable to the lying-in chamber.
The form of puerperal fever was similar to that present in Belle-
the Hospital about ten years ago. It differed from puerperal fever as it was usually described in text-books. There was a good deal of puerperal diphtheria, usually commencing at the vulva and extending up the vagina. In only a very few cases had there been any evidence of its having reached the uterus. It was very seldom ushered in with marked symptoms. It commenced with a small and frequent pulse, and chill, but the temperature during the first few days seldom rose above 100° F. It then became intermittent, perhaps 101° in the morning and 102° in the evening, and there were occasional rigors. If the vulva were exposed (and it always was during twenty-four hours after confinement at intervals of about six hours), one could see a slight, almost imperceptible blush come over any lacerations that might be present; in from one to three days it would have assumed a grayish, ash color. Then typhoid symptoms developed. The treatment had consisted largely in the use of carbolic acid. He had applied it at the seat of the diphtheritic spots sufficiently strong to produce almost a caustic effect, but as soon as the slight slough separated the diphtheritic process became worse than before. He approved of the treatment advocated by the author of the paper, and thought it might be carried out in its details in hospital practice. In private practice it would be more difficult.

Dr. W. Gill Wylie referred to a paper which he read before this society about six months ago (see the "New York Medical Journal" for June 23, 1885, p. 679), in which he advocated certain antiseptic methods in the lying-in chamber, and said that by observing them he had had only a single case in which there had been a rise of temperature after delivery, in which case the forceps had been used, labor having lasted about eighteen hours. The elevation of temperature was only slight. In 1871, while interne at Bellevue Hospital, he treated thirty-six lying-in women on principles directed against sepsis, and in not a single case did puerperal fever develop. He thought it important to secure free drainage of the womb, especially in delivery before term. If necessary, a drainage-tube should be introduced. He advocated antiseptic methods even in private practice, and carried out in detail.

Dr. W. E. Gillette had been connected for some years with the Maternity Hospital service, and said that there could be no question as to the importance of the suggestions mentioned by the author of the paper for the prevention of the rise and spread of puerperal fever in the Maternity Hospital. There might be some difference of opinion as to the methods to be adopted. The last antiseptic seemed to be bichloride of mercury, and, of course, as it was the most recent, we must bow to it, but he was not sure that it should supplant the others, which had stood the test of time, and given such excellent results. With regard to the dressing, he could perhaps see benefit in the external bandage, but he did not think the lint and the oakum could be retained in position in a manner to serve as a Lister dressing; as the patient moved about in bed, the dressing could not be kept closely in position so as to prevent the entrance of disease germs. He hoped the results obtained by Dr. Garrigues would continue, but he must, from an experience of years in the same institution, advise the doctor, while he was hopeful, not to be too sanguine, but to watch and pray. He referred to the great mortality existing among the puerperal patients at Bellevue Hospital just before their transfer to the Maternity Hospital some years ago. By simple cleanliness, without the use of bichloride of mercury or of Listerism, that mortality was then reduced almost to a minimum. He believed that in strict cleanliness lay the secret of success in the management of lying-in institutions.

Dr. A. S. Hunter found himself quite in accord with the author of the paper regarding cleanliness and the use of antiseptics. There was no question but that we were having better results in labor since having undertaken to disinfect and cleanse the parts more thoroughly than before. He believed, with Dr. Gillette, that it would be impossible to prevent the entrance of germs by means of the pad shown by Dr. Garrigues. He preferred the Lyman tube with which to make injections. He did not think it difficult to carry out the details of antisepsis in private practice.

Dr. S. Barchus offered his unqualified condemnation of the practice of antiseptic injections after normal labor, and he was very glad indeed that Dr. Garrigues had not said anything at all in advocacy of that practice. He believed that the practice, which seemed to be becoming customary, must cease. He spoke of injections after normal labor only. Out of nine hundred cases of labor which he had attended during the past twenty years, among which there were many with complications, there had been but one death preceded by febrile symptoms, and he was not sure that in that instance it was due to a septic process. Since Dr. Wylie read his paper before the society, about six months ago, he had employed antiseptic injections rather extensively, using a three-per-cent. carbolic-acid solution, and his experience had been somewhat singular. The injections were made twice a day. He had seen six cases under this treatment in which fever, undoubtedly due to a septic process, had developed after the fifth day. Antiseptic prophylactic injections had been largely tried in Germany, and were being abandoned, as better results were obtained without them than with them. Dr. Barach considered prophylactic injections as objectionable, because it was detrimental to disturb the patient after labor for any purpose: she should be kept as quiet as possible. It was impossible to introduce a syringe without disturbing the genital organs more or less. Very few nurses could make the injections properly. The injections might displace clots which had been formed to close vessels, or they might tear recent adhesions. Collapse and shock had been produced. These facts had been verified by clinical experience. In normal cases, he believed that simple cleanliness before, during, and after labor would accomplish everything necessary to carry the woman safely through childbed. He referred to the practice of introducing iodine pencils into the uterus, made up of iodine, starch, and glycerin, in cases of injury to the genital tract, and to be renewed when the clots again became offensive. This practice had been attended with good results.

Dr. F. V. Wurr reported that antiseptic vaginal injections were employed in Bellevue Hospital as long ago as 1856, when he was interne. With regard to pressing out the placenta, he had never been able to do it.

Dr. J. P. Garman had attended something like four thousand cases of midwifery, and had not had more than two cases of puerperal peritonitis. During the first thirty years of his practice he used no antiseptics whatever. He did not believe in meddlesome midwifery, and there was too much of it. In normal labor the physician who simply observed strict rules of cleanliness would have the best results. A change of the clothing, of the bed, sheets, and blankets, the use of clean towels, and the application of a clean napkin to the genitals after delivery, were all that was necessary, and, if we used prophylactic injections, we should simply be violating the laws of nature, and take the risk of opening the mouth of vessels, of injecting the fluid into the Fallopian tubes, and of doing a variety of injuries.

Dr. J. C. Perkins had been waiting since 1875 to see carbolic acid go out of use as a so-called antiseptic, and he believed that the time had now arrived. It should be supplanted by bichloride of mercury, which was really a good germicide.

Dr. Garnoutes, closing the discussion, said Dr. Murray was more able than anybody else to appreciate the success obtained,
since he had had to combat the same evils. Undue stress ought not to be laid on the fact that he (Dr. Garrigues) had obtained a new ward, for this was only one out of three used for the service. Of the two others, one, the former delivery-room, had been looked upon as very suspicious by Dr. Murray himself, and in the other the worst kind of puerperal diseases had formerly occurred; but, since the new treatment had been instituted, the results were alike good in all the wards. Dr. Murray's remarks in regard to private practice had been sufficiently answered by Dr. Wylie. Dr. Garrigues was much surprised at Dr. Gillette's remarks, since he (Dr. Garrigues) had just given the statistics for the year 1872; he had taken them from Dr. Gillette's own report; and there had been, as stated in the paper, 579 mothers delivered, 15 of whom had died. This might have been a great progress as compared with the enormous mortality in Bellevue Hospital, but there was no comparison between that and the results now obtained. Dr. Hunter had said the dressing would become folded so that the air would have free access. As a matter of fact this was not so. The sizes indicated for the lint and the oiled mm-lin had been found by actual observation to be the best, and with these two pieces of the dressing, which composed the true antiseptic part of it, were not folded. The lint lay entirely smooth, and the oiled muslin just touched the inside of the thighs, and here each edge was turned slightly forward. The oakum, on the contrary, was meant to adapt itself to the space found between the thighs so as to form a bulky mass there; and the muslin, being spread out by means of the pins fixing it to the binder, and being raised between the thighs by the underlying oakum, was likewise smooth and not folded, the width of the bandage where it was fastened to the binder being five inches. Lyman's silver tube would, like all metals, be corroded by the bicloride of mercury. If the terminal opening of the glass tube should happen to be clogged, there was one on the side, a quarter of an inch from the end, and in practice he and his assistants had found that it worked perfectly well. We ought to distinguish between intra-uterine and vaginal infections. The former constituted a delicate operation, which ought always to be performed by the accoucheur himself, and only on special indication. They were indicated when hands or instruments had been carried up into the interior of the womb, because, in spite of the antiseptic precautions used by the accoucheur, the risk of contaminated air being introduced along the hand, arm, or instrument was so great that it was much better to wash out the uterus than to run that risk. They were likewise indicated if the child had been dead for some time, and if the liquor amni was patrid. Vaginal infections were much less dangerous, and might be left to the nurse; but even they might give rise to infection, and he maintained that it was one of the chief advantages of his dressing that they became superfluous. The placenta was always expressed by Credé's method, which succeeded in all cases except in those rare ones when it was adherent, and its removal even by the hand in the uterus was difficult. In about three hundred cases composing his last two services this had only happened five times. Retained placenta had never occurred. Labor was a normal process, but it was not normal to give birth to a child in a hospital, consequently the artificial surroundings called for artificial means to prevent mischief. Cleanliness was good, but had proved insufficient, not only in the Maternity Hospital, but in the European lying-in asylums, in which the mortality had decreased immensely since the introduction of antiseptics.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held December 13, 1888, Dr. J. H. Messer in the chair.

EXUDED HYPERTELEPHORPHY OF THE HEART (weight, forty-eight ounces).—Dr. Charles W. Delles showed the specimen, and made the following remarks: The patient from whom this specimen was obtained was a young man, eighteen years of age, who came under my care in February, 1882, in an attack of muscular rheumatism, principally affecting the shoulders. I found at that time great oppression of breathing and a dilated and hyper- tensioned heart, with a harsh, strong mitral systolic murmur. His urine contained biliary coloring matter and a great excess of urates; there was no albumin nor sugar, and the chlorides and phosphates were very deficient. In the sediment, only amorphous urates were found. The treatment employed included the administration of infusion of digitals, with iron and strychnine. At one time, believing it might mitigate the violent action which I attributed to the real hyperthyroph, I gave him veratum viride, but it did no good. I did, however, afford prompt and apparently substantial relief from some of the symptoms by the use of iodide of potassium in twenty-grain doses thrice daily. After using this for a week, I noted in my case-book: "Sleeps well; eats well, cough very slight; urine clear; can not hear the old warmer (perhaps barely); both heart-sounds audible and pretty clear; action of heart fair." (It had been very tumultuous.) After doing well for six weeks, the patient had a new attack of gastric uneasiness, dyspepsia, and more or less cyanosis. On the night of May 10th I gave him a fifth of a grain of hydrochlorate of pilocarpine hypodermically (in the left arm), under the influence of which he sweated, but had no salivation. The next day he had a large edematous swelling of the left side of his neck, below the jaw, reaching to the middle line in front. This increased up to the evening, and gradually subsided in three days. About this time fluid began to accumulate in the abdomen and thorax, and there was, of course, edema of the feet and legs. There was now a most beautiful water-hammer pulse over the femoral arteries, below Poupart's ligament. The pulsation was intermittent, and had a reduplicated sound, like this: — — — — — — — — etc.

Three weeks later another severe attack occurred, and another about three weeks after this. There was now considerable albumin in the urine, together with hyaline tube-casts. When his attack came on, which was at night, I gave him one third of a grain of hydrochlorate of pilocarpine hypodermically, which produced free sweating and brought about two fluid-ounces of saliva. His pulse came down from 140 to 100 in half an hour; but the dyspepsia abated only temporarily, the restlessness continued, the cyanosis increased, the respiration varied from 35 to 60 a minute, then the bowels moved involuntarily, his lungs seemed to fill up with edema, and he died asphyxiated.

Autopsy, made the next day, with the assistance of Dr. Forman and Dr. J. H. Musser.—The points of interest were as follows: There was general edema of the feet and legs. The face, neck, and chest were covered with purpura-like spots and patches. The abdomen contained about two quarts of clear serum, and each plural cavity nearly as much. The lungs were normal, but small, and occupied the upper part of the chest. They were quite edematous. The liver was slightly fatty. The spleen was of normal size, but very hard and tough. The kidneys were large, congenitally lobulated, and in a state of cryo- notic hyperthyroph. The heart was enormously hypertrophied, weighing, when all the adherent parts were removed, forty-eight ounces. The pericardium was so uniformly attached to it that it could not be removed, and there was absolutely no pericardial cavity. The right ventricle contained about six ounces of soft post-mortem clot. The left side contained about two ounces of like material. After the heart had been opened and well washed, it weighed forty ounces. All the valves and blood-vessels were healthy. The tricuspid and aortic valves were
quite competent; the narial orifice was enormous, measuring two inches and a half across. Every part of the heart was hypertrrophied, and to about the same degree. The whole organ, which I here saw, was of about the size of a bullock's.

The points of interest in this case—apart from the curiousness of the specimen—seem to be the following: the comparative immaturity of the kidneys, the absence of signs of adherent pericardium, the benefit derived from the use of iodide of potassium, the temporary disappearance of the very marked systolic and presystolic mitral murmur, and the parotid swelling following the hypodermic injection of pilocarpine into the arm of the same side.

The Chairman remembered the case distinctly, both before and after death. He had marked out on the chest the dimensions of the heart, and had made them out as enormous, extending especially to the right. Furthermore, he thought there was a double mitral murmur. The only apparent cause for the hypotrophy was the adherent pericardium. He would like to know what Dr. Henry thought of the correctness of this explanation.

Dr. F. P. Henry said that the heart presented was remarkable, not only for its enormous size, but also for the absence of the usual causes of cardiac hypertrophy, there being neither valvar disease nor obstruction in any part of the circulation. During his student days he had seen some very large hearts in the collection which Professor Alonzo Clark was accustomed to show his class, but he would not trust his memory so far as to affirm that any one of them was as large as the one just shown.

Dr. MacConnell had seen a case, in a member of the Modjeska troupe, where post-mortem examination showed an enormously hypertrophied heart, with adherent pericardium and markedly granular kidneys. In that case the hypertrophy was clearly due to the kidney trouble.

Dr. Formad thought that the heart in Dr. Dulles' case was unique as to size. Dr. Robinson, of New York, had recently reported a case of hypertrophied heart weighing fifty-six ounces, but Dr. Dulles' specimen had been weighed after the removal of clots, etc.

The Chairman asked whether other members of the patient's family did not have hypertrophied hearts without valvar lesions. If such was the case, taking into consideration the age of the patient, it would be well to bear in mind the probability of the hypertrophy having been in part secondary to the pericardial adhesions and in part idiopathic in origin.

Dr. Dulles said that there was a tendency to hypertrophy of the heart in one sister, and that the murmur was double at times.

**Calcified Pericardium: Double Mitral Disease.**—Ella S., white, aged twenty-three, was admitted into the University Hospital in September, 1880, complaining of palpitation and dyspnea, and suffering from an edema and ecmatization of the lower extremities. She was a girl of regular habits, somewhat exposed to changes of weather and to wet, doing no very hard work. She had had the diseases peculiar to childhood, but never rheumatism or chorea. Her father had had acute articular rheumatism, and died suddenly. Beyond this there was nothing peculiar in the family history. Three years before admission she first noticed slight palpitation and dyspnea on exertion. For some time before that she had been subject to frequent attacks of epistaxis. One year afterward droopy appeared in the ankles and spread upward. The palpitation and dyspnea became more troublesome, her flesh and strength failed, and she was compelled to quit work and come into the hospital. When first seen, she was pale, anemic, weak, and breathless on exertion. The heart's apex beat was in the seventh intercostal space, one inch to the outer side of the nipple line; its action strong and heaving. Best heard over the apex beat, but transmitted feelly toward the base of the heart and well out into the axilla, was a loud, blowing systolic murmur. There was no pain in the heart or tenderness on pressure over it, nor had there ever been. Over the lungs were scattered moist rales, and the respiratory murmur was harsher on the left side than on the right. There was slight cough, with some mucous expectoration. The lower extremities were edematous, and the abdominal cavity was about half filled with fluid. The liver was slightly enlarged. The urine was normal in quantity, and contained neither albumin nor casts. Under treatment, the urine became copious, the edema gradually disappeared, and the heart's action became stronger and more regular. In a few days friction sounds appeared at the base of the right lung. Any slight exposure would bring on an attack of intense congestion of the lungs, with dyspnea, that often threatened life; and with these attacks there was frequently congestion of the kidneys, with suppression of urine. Between the attacks the heart retained its power well, though it slowly dilated. At intervals she complained of dull pain in the hepatic region. The rough respiration noted at first over the left lung became more and more marked, till finally, over a small area just below the spine of the scapula, it had developed into bronchial breathing; friction sounds came and went, and there were always moist rales scattered through the lungs. The expectoration was mucous or, rarely, serous-purulent. Three months after she came under observation there was developed at the second right intercostal space, and carried out into the arteries of the neck, a systolic murmur differing in pitch and tone from the mitral systolic. About this time, too, she complained of pain in the heart whenever its action was excited. Fourteen months after she was first seen there was noticed, just to the inner side of the apex beat, and carried indistinctly toward the base, a harsh, short murmur, immediately preceding the systolic murmur, and separated from it by an exceedingly short but appreciable interval. This murmur was noted on several occasions afterward, but was much oftener absent than present. Its appearance and disappearance seemed to be attendant on no definite conditions. Soon after it was first noticed she had several attacks of epistaxis, and afterward occasional slight hemorhages from the lungs. She was discharged in March, 1882, and was admitted again last September. She had been gradually losing ground. Seven months before, she took cold, and the droopy returned and persisted. When seen, the whole body was edematous, and the abdomen was enormously distended. The apex beat was in the fifth interspace, in the mid-axillary line. The systolic murmurs were perhaps louder, but, beyond this, had not changed. Over an area between the left nipple and the sternum was heard a harsh, lowpitched, presystolic murmur; it was much more apparent than the former presystolic murmur, but had the same characters; its point of maximum intensity was just to the left of the sternum; it was constant. The respiratory murmur over the left lung was very much harsher than over the right. Below the spine of the scapula the breathing was sometimes blowing, with no mucous rales. The expectoration was mainly frothy mucus. She died, three weeks after admission, in a fit of dyspnea.

**Spindle-celled Sarcoma of the Lower Jaw.**—Dr. MacConnell also showed for Professor Pancoast a section of a large tumor of this sort. The patient was a man twenty-four years old. The growth had existed for about three years. The eggshell crakle was readily elicited, the growth being of central origin. On section, it presented a whistit appearance, and was permeated by spicula of bone.
Reports on the Progress of Medicine.

SURGERY.

BY CHARLES B. KELSEY, M.D.

(Concluded from page 702.)

THE TREATMENT OF THE SAC IN OPERATIONS FOR STRANGULATED HERNIA.—The different plans of treatment of the sac in hernaotomy are concisely pointed out by Mr. McGill ("Brit. Med. Jour.," Sept. 15, 1883). There are two courses open to the operator. One is the old plan of letting it entirely alone which is described in the text-books. The other consists in fastening it up and thus sealing the peritoneal cavity. The extra-peritoneal operation can not as a rule be practiced, because of the prolonged duration of the strangulation, or inability to reduce the gut, or the presence of omentum requiring removal.

The author details four methods of fastening up the sac after the operation: 1. The sutures may be passed through both skin and sac, both being approximated at the same time; 2. The margins of the sac may be separated from the tissues external to it, and brought together by catgut, the skin being united by a second row of sutures; 3. The neck of the sac may be ligatured and the sac removed; 4. The neck of the sac may be ligatured and the sac left in position. The first plan is particularly adapted to cases in which the skin and sac are adherent and form one thin coat over the hernia, as in umbilical hernia. The second is adapted to cases in which the complete separation of the sac is impossible. The third the author believes to be the best, as it offers two great advantages: it effectually closes the abdominal cavity, and thus, to a certain extent, it serves to prevent a recurrence of the rupture. In other words, it diminishes the risk and improves the result of the operation. The separation of the sac is sometimes a tedious and sometimes a simple operation, and is more apt to be simple in femoral than in inguinal hernia. When separated, a stout No. 3 catgut ligature is applied, and the sac is removed with scissors. The fourth method the author has never seen tried, but believes it to be particularly adapted to cases of congenital hernia where the sac is the tunica vaginalis and plainly can not be removed. The author supports his conclusions by the statistics of twenty-seven operations which were more or less favorable.

A METHOD OF REDUCING DISLOCATIONS AT THE ELBOW.—Dr. J. E. Kelly ("Dublin Jour. of Med. Sci.," July, 1883) recommends the following methods of reducing obstinate dislocations of the elbow joint: They are generally reduced without much difficulty, but the operator occasionally encounters an amount of resistance which demands the application of pulleys or the aid of assistants. In other instances, in which a complicating fracture is suspected or recognized, considerable force may be essential to the diagnosis or treatment, and it is expedient that, while perfectly under control, this power should be applied with great steadiness. Again, in long-standing dislocations accompanied by extreme rigidity and consequent loss of function, authority, with the object of permitting efficacious treatment by passive motion, sometimes sanctions the fracture of the olecranon process. In any of these contingencies the procedure which the author recommends permits of the necessary treatment in the most satisfactory manner.

The operator sits on the corner of a table, at the end of which the patient is placed upon a chair. The injured limb is drawn under the surgeon's proximal thigh, which rests, close to the joint, on the anterior surface of the humerus, while the olecranon is accurately placed on the anterior surface of the lower third of the distal femur, and the proximal foot is hitched behind the other leg, which is flexed firmly against the frame of the table. In order to obtain the most favorable fulcrum, the surgeon fixes his proximal elbow against the antero-lateral aspect of his corresponding thigh, and, grasping the wrist of the patient with both his hands, reduction is effected by the simultaneous and co-operative action of the muscles of the arms, back, and thighs. Fixation and counter-extension are supplied by the powerful thighs of the operator, and coaptation is effected with great nicety by the backward pressure of the proximal femur against the anterior surface of the humerus, while the distal femur forces the olecranon forward.

In the lateral modifications of the posterior luxations the reduction is generally effected by the same manoeuvre which is employed for the simple form of dislocation; but, should special coaptation be necessary, it is at the disposal of the operator, as, when aided by the powerful constraining pressure of the thighs, the proximal arm can supply sufficient traction and stability, while the other is unoccupied and in the most advantageous position to apply any additional manipulation, which may, if desirable, be afforded by an assistant. If the condition be such that the full extending force of both arms be required, the isolated rural surgeon can, with a little ingenuity, render himself independent of professional aid by fixing the bone of the arm or forearm, which is displaced inward, by a bandage passing around his own loins, and by making lateral traction on the bone or bones displaced outward, by another bandage attached to his foot, and passing over his knee as over a pulley.

The author also details a somewhat similar procedure for the reduction of anterior dislocations.

TREPHINING FOR DIFFUSE OSTEO-PERISTOSIS.—Dr. Schwartz ("Revue de chir.," No. 5, 1883) furnishes some interesting remarks on the trephining of bone in certain cases of diffuse osteo-periostitis in the adult. After detailing a case, he raises the following question: Given, rapid inflammation of the whole of a bone which has previously been the seat of ostitis; absence of the medullary canal as a consequence of the old inflammation which has definitely closed it; absolute powerlessness of the trephine under the conditions—what should be the course of the surgeon under such circumstances?

The two former propositions are not insisted upon. They are well-known facts of physiology and pathological anatomy. But the last two possess much greater real interest. It is certain that such a case as is described is peculiar. Not only did the inflammation seem to have invaded, from the very commencement, the entire length of the bone, but it was impossible to evacuate with the trephine the pus which formed, because it was not in what could properly be called a collection.

Assuredly trephining constitutes an excellent intervention when it permits the flow of pathological products and the washing out of the cavity, osseous or other, which contains it; but of what use is the opening of the bone when the pus is infiltrated, when for all its length it is, so to speak, converted into a sponge? The author affirms that, had he immediately applied the trephine to two parts at a certain distance from each other, and had observed the condition not only of the diaphysis but the epiphysis, he should not have hesitated to have at once amputated the thigh, and, perhaps, might have saved the patient. In view of this condition, he again asks: When, in a child or youth who has already shown the signs of a diffuse osteo-periostitis, there is produced a new inflammation, rapid and total, with grave general phenomena, and when, by the aid of the trephine early applied to two points simultaneously, purulent infiltration of the bone for a great extent has been recognized, is it not better immediately to perform amputation of the thigh than to rely upon trephining, even repeated, and upon consecutive
arthrotomy? The cases in which it might be possible to totally exsect the bone, as in the fibula, are excluded.

Hemorrhage in Hip-Joint Operations.—Mr. Jordan Lloyd (“Lancet,” May 29, 1883) describes a new and valuable method of controlling hemorrhage in amputation at, or excision of, the hip joint, which we will give in his own words: "The limbs about to be operated upon should first be emptied of blood by elevation. This will occupy only a few moments, and may be executed during the administration of the anæsthetic. Elevation, combined with gentle friction toward the trunk, renders parts as exsanguineous as the at times undesirable Esmarch’s roller. A strip of black India-rubber about two yards long is to be doubled and passed between the thighs, its center lying between the tuber ischii of the side to be operated on and the anus. A common calico thigh roller must next be laid lengthwise over the external iliac artery. The ends of the rubber are now to be firmly and steadily drawn in a direction upward and outward, one in front and one behind, to a point above the center of the iliac crest of the same side. They must be pulled tight enough to check pulsation in the femoral artery. The front part of the band passing across the compress occludes the external iliac and runs parallel to and above Poupart’s ligament. The back half of the band runs across the great saccular notch, and, by compressing the vessels passing through it, prevents bleeding from the branches of the internal iliac artery. The ends of the bandage thus tightened must be held by the hands of an assistant placed just above the center of the iliac crest, the back of the hand being against the surface of the patient’s body. It is a good plan to pass the elastic over a slip of wood held in the palm of the hand, so as to diminish the pain attending the prolonged pressure of the rubber bandage. In this way an elastic tourniquet is made to encircle one of the innominate bones, checking the whole blood-supply of the lower extremity. The elastic bandage may be secured above the iliac crest, in the usual manner, with tapes, and may be prevented from slipping downward by being held with a common roller tied securely over the opposite shoulder. Experience shows, however, that no mechanical means answers so well as the hand of a trusty assistant. When the band is once properly adjusted, the assistant has only to take care that it does not slip away from the compress or over the tuber ischii. The former is prevented by securing pad and tourniquet together with a stout safety-pin, and the latter by keeping the securing band well above the iliac crest, or even more safely by looping a tape beneath the elastic, near the tuber ischii, passing it behind the sacrum and having it held in that position. The solid rubber tourniquet may be used in place of this bandage. I prefer, however, the bandage. The soft parts are less damaged by reason of its greater breadth, and it is less likely to roll off the compress placed over the external iliac.”

This ligature, being entirely above the limb, is out of the way of the surgeon in any operation about the joint. The great trochanter is entirely exposed, the hip being free upward as far as the iliac crest and inward to the perineum. It has all the advantages of Davy’s lever, and several in addition. 1. The simplicity and certainty of its application. 2. The certainty with which the vessels are controlled, regardless of the movements of the patient or manipulations of the operator. 3. The freedom from danger of injury to the rectum or abdominal contents. 4. Its applicability to cases where the rectal lever could not be employed, as in strictures of the bowel, intra-pelvic growths, and arterial abnormalities. 5. It requires no special apparatus.

With this method the author has done four almost bloodless amputations at the hip joint, and several minor operations.

Suprapubic Lithotomy.—Dr. Villeneuve (“Rev. de chir.”)

No. 9, 1883) discusses at considerable length the propriety of the substitution of the suprapubic for the different perineal operations as a general rule in cystotomy. He proposes to examine whether, with the antisepsic methods and the new perfection to which the suprapubic operation has been brought, it may not be practiced with advantage in all the cases for which the perineal operation is now done; in other words, in all cases not suitable for lithotomy. He arrives at the following conclusions: 1. The suprapubic operation, which, up to the present time, has been an exceptional method, appears worthy to become the general rule of practice, though not the exclusive one. 2. It should be practiced with all the modern improvements: distension, injection of the bladder, forcing back of the peritoneal cul-de-sac, antisepsic precautions, etc. 3. The suture of the bladder should be avoided, but it remains, nevertheless, the ideal to pursue, which, if realized, would place by the immediate union the superiority of the suprapubic operation beyond all question. 4. The high operation is still, as in the past, a necessity in cases of large or encysted calculi, of intolerant bladder, and of impermeable or contracted urethra or vagina. 5. It is exceedingly probable that it will become the favorite operation, in old men and adults, in cases where lithotomy is not applicable, and which are now treated by the perineal operations. 6. In male infants it may be presumed that it may prove at least equal to the perineal operations, but the happy results of the latter render its substitution in this class of patients less important. 7. With young girls, and girls at the age of puberty, the high operation will be the chosen one. 8. In married women the choice between the high and the vaginal operations remains undecided, and requires new study. 9. An inflammatory affection of the uterus, a notable deformity of the bladder through the malposition of the uterus, and especially cystocele, should lead to a decision in favor of the high operation. 10. The hypogastric operation in adult females should be preceded by dilatation of the urethra. 11. The constitutional affections and diatheses furnish no special indications for the choice of operation. 12. The same applies to the lesions of one or other parts of the sympatheticplexus, which either operation may entail.

Surgical Interference with Tumors of the Bladder—Dr. Bazy (“Anœgles des maladies des organes génito-urinaires,” September, October, 1883) arrives at the following conclusions respecting surgical interference with tumors of the bladder in the male:

1. Intravesical tumors in men, which, up to the present time in France, and up to a few years ago in other countries, have seemed beyond the resources of surgery, may be usefully treated and cured. 2. An operation may be done for malignant growths as well as for benign, for tumors pedunculated or sessile. It is contra-indicated in cases of generalization, of adherence to neighboring organs, of diffuse neoplasms, and of serious changes in the kidney. 4. The basis upon which surgical intervention should rest is an exact diagnosis made by the aid of the rectal touch, joined with hypogastric palpation and exploratory catheterism of the bladder. 5. Direct digital exploration is not permissible except when the gravity of the symptoms demand operation, and intervention has been decided upon. This digital exploration may be made by the perineal method (boutonnière), or by the hypogastric. The latter, which does not seem to be more dangerous than the perineal, allows of permitting the completion of the operation, if it be deemed advisable. 6. The operation may be curative or palliative. 7. The former applies to pedunculated, whatever may be their nature, and to benign tumors, whether pedunculated or not. 8. The second, or palliative operation, is designed to combat certain symptoms which constitute the gravity of the affection—as hematuria, and especially the violent pains which accompany or follow
miturition, and the frequent desire to urinate. It consists, after the ablation of the tumor, in leaving a vesical fistula. It is thus the analogue of an artificial anus in cancer of the rectum. 9. The high operation should be preferred to the perineal, which, however, may suffice in certain cases. 10. The use of the rectal inflator of Peterson is almost indispensable for the high operation. 11. The median incision is not always sufficient, sometimes an L-shaped incision being necessary, and a curved one, forming an upper flap, being sometimes of advantage. 12. The tumor may be removed by the ligature : by torsion, if it be pedunculated; by detachment, by scraping, or by causing a loss of substance in the bladder. 13. This loss of substance may be total—that is, extend through all the coats of the bladder—or partial, involving only the mucous membrane and the internal muscular layer. 14. The total loss of substance appears to be necessary only in cases implicating the posterior wall of the bladder, or possibly the lateral walls. 15. The suture is indispensable in cases of total loss of substance, and is serviceable in cases of partial loss. 16. The fear of infiltration resulting from an operative wound of the bladder is not as real as it has been supposed. 17. Every wound, united or not, contra-indicates occlusion of the bladder. The employment of the two siphon tubes, back to back, of MM. Périer et Guyon, appears to the author to realize the best conditions for the easy escape of urine.

Chylocele of the Tunica Vaginalis.—Dr. W. M. Mastin ("Annals of Anat. and Surg.,” May, 1883) contributes a very interesting article on this affection, which he believes to be less infrequent than the small number (five) of reported cases would indicate. These five cases, one of which is his own, he has carefully analyzed. He finds the cause of the affection to be a rupture of a lymphatic vessel and an extravasation of its contents into the tunica vaginalis, the lesion being the same as in the analogous affections chyluria, chylothorax, and chylous peritoneal dropy.

He also finds that climate has a marked influence in this as in other lymphatic affections, four of the five cases having been residents of warm latitudes. In three of the cases the chylocele was preceded by blemorrhagia, and the author believes that in his own case the lymphangitis resulting from this cause was a direct exciting cause of the lymphatic engorgement, rupture, and extravasation.

In the author's case, and in that of C. H. Mastin, a lymph varix was found on the anterior aspect of the testicle at its junction with the cord, from which, after the opening of the sac, lymph could be seen to exude. In the former a single vessel was found opening at the most prominent point of a small tubercle, while in the latter the mouths of three or four distinct vessels were seen after the cutting off of the varix.

Regarding the diagnosis, the appearance of the tumor can not be distinguished from that of an hematocele, but a non-translucent tumor of moderate size, fluctuating, associated with enlarged inguinal glands or any lymphatic disorder, the patient, at the same time, presenting the history of one or more blemorrhagia, and especially of residence in a tropical climate, should form a combination of symptoms quite sufficient to awaken suspicion as to the nature of the malady.

The method of treatment by free incision into the sac and ligation of the exuding vessel is hesitatingly recommended. By this procedure every portion of the cavity is exposed to view, and the oozing point can easily be seen and secured.

The Radical Cure of Varicocele.—Mr. R. L. Pinching ("Dublin Jour. of Med. Science," May, 1883), led by the success of the treatment of hemorrhoids by injections, has been trying the same plan for the radical cure of varicocele. He has used liquor ferri chloridi with success in one case, but with such an amount of pain as to cause syncope. In two other cases he has used strong tincture of iodine with equally good result and with less pain. He used in each case a syringeful of the solution, causing a considerable extravasation into the areolar tissue around the cord. All of the patients were able to attend to their business on the day following the operation, using simply a suspensory bandage.

New Inventions, etc.

AN IMPROVED INHALER.

By R. W. Mitchell, M. D., Memphis, Tenn.

The accompanying woodcut so clearly represents the instrument that an explanation of it is hardly necessary. This inhaler is made of tin. It is divided by a diaphragm of wire gauze into two nearly equal parts. The letter a shows the mouth-piece with the wire gauze inside, and openings for the admission of air. The cover b, opens by a hinge on the side, and allows the introduction of cotton cloth or other material, which lies on the top of the wire diaphragm, and receives the ether.

There is a sliding button, c, which goes between the fingers, and facilitates the handling of the instrument. When not in use, this button slides in.

This inhaler has been fully tested, and is recommended to the profession on the grounds of:

1. Durability. 2. Cleanliness. 3. Cheapness. 4. Economy of ether, the amount being far less than that consumed by other inhalers.

It is manufactured by Messrs. George Tiemann & Co., New York.

Miscellany.

Therapeutical Notes.—Apomorphine in the Treatment of Hysterical Epilepsy.—In a recent number of the "Medical Times and Gazette" T. Hammond Williams, L. R. C. P., gives notes of two cases of hysterepilepsy in which he made use of apomorphine. Mental perturbation, he states, was marked in both cases. In one of them, he thinks, it was evidently the result of the uterine function being in abeyance. In the same case the vaso-motor system also seemed to be at fault, for, on pricking the skin, no blood appeared from the cutaneous arterioles and capillaries. The general nutrition and the condition were normal. Ovarian compression and the use of hydrate of chloral having proved of no avail, hypodermic injections of apomorphine were employed, one fifteenth of a grain at each injection. The first two injections failed to provoke vomiting, their action being retarded, the author thinks, by the fact that the patient was still under the influence of chloral. Finally emesis took place, followed by prostration, drowsiness, and sleep. "The drug," says the author, "no doubt produced
MISCELLANY.

enemies by being carried into the circulation to the great nervous center in the medulla oblongata, where, by its action, it excited vomiting, besides causing nausea and depression of the circulatory system, and diminishing the muscular and nervous power. It therefore acts as a direct emetic upon the so-called vomiting center, but as an indirect emetic in relation to the stomach."

Kwéiré on an Antipyretic.—Dr. Henry Ashby, of Manchester, in a short communication to the "British Medical Journal," testifies to the decided and certain reduction of temperature accomplished by the emetic or tonic principles of this medicine, and adds that it has the advantage over quinine of not producing headache, singing in the ears, or other unpleasant effects, although the impure drug employed at first was so, altogether free from these objectionable properties. As the antipyretic, its effect is of brief duration, it is better, he thinks, to give small doses frequently repeated. To avoid its unpleasant taste, it may be given in gelatin capsules. He thinks that its effect is limited to reducing the temperature, and that therefore it acts only as a palliative, being wholly inadequate to cut short the course of any of the specific fevers. Using the pure drug, he considers it safe, even in large doses. (Inasmuch as Dr. Ashby begins by giving some information in regard to the chemistry of the drug, and expressly states that it is an artificial substance (oxyethylmethylhydratetlurea = C13H12N2O), it is not a little singular that he falls into the common error of spelling its name without the final e — a termination which should be given to the names of all alkaloids.)

The French Cholera Commission.—The report of the three surviving members of the Pasteur Mission is still unpublished. It is stated that it will be very elaborate, and will be presented to the Minister of Agriculture. It consists of the questions of public health. Meanwhile, M. Pasteur has been interviewed, and it appears that he is at once pleased and disappointed with the results of the expedition. He is disappointed because M. Thillier and his colleagues were not able to inoculate any animals with the cholera germ, apparently because they did not succeed in discovering it; but he draws consolation from the fact that the German inoculation-experiments were also without result. Indeed, M. Pasteur almost despaired of final success until he can find some man of sufficient public spirit to deliver himself over as a subject for experiments of this kind. Meanwhile, the mission has done much useful work, and has limited the field for future inquiries.

Med. Times and Gaz.

A Curious Malposition of a Tooth.—In a recent number of the "Lancet," Dr. Gopal Chunder Roy relates the case of a Hindoo lad, aged fourteen years, who presented himself for treatment at the Soree Charitable Dispensary, for what he considered to be a tumor growing within the nasal cavity. He noticed a foul smell in his breath about four months before, attended with catarrh and sometimes a bloody discharge from the left nostril. For the previous two months the growth had been observed to occupy the left cavity, where it seemed to be attached to its wall at its upper part; its free end was looking downward in the shape of a truncated cone. Arrangements having been made for plugging the posterior nares, in the event of uncontrollable hemorrhage, the tumor was seized with dressing forceps and extracted. It proved to be a tooth of the shape of a cuneiform. There was very little bleeding after extraction, and this was stopped by alum lotion. The free extremity was covered by enamel, which stopped short at its junction with the root. The root was deeply embedded in the side and upper part of the antrum. The boy had got his set of permanent teeth, with the incisors and canines entire on either side. There was no deformity of the jaw and no swelling or cystic formation. It was clearly a case of extra-follicular development and eruption of a tooth in a wrong place, the peculiarity being that while in reported cases of like nature the crown of the tooth shows itself at the floor of the nasal cavity from below upward, in the present instance, by some freak of nature, the dental follicle was transposed, and the eruption was from above downward. The tooth has been sent to the Royal College of Surgeons' Museum.

Bone-Changes in Rickets.—Dr. J. S. Bury read a paper on this subject before the Microscopical Section of the Manchester Medical Society, and illustrated his remarks by numerous specimens, sections, and drawings. After a brief sketch of normal ossification, which included the description given recently by Kassowitz of "metaplastic ossification," Dr. Bury described the chief variations met with in a growing ricketsy bone. Briefly, these were as follows. In moderate rickets, the columnar zone of the cartilage was lengthened and widened, owing to an increased growth of the cells; in more advanced cases, the rapidly growing and soft cellular columns, being compressed between the firm cartilage above and the bone below, also became arched, and thus the epiphyseal swelling was greatest at the middle. There was an increased formation and enlargement of the vascular canals in the lower zones of the cartilage; these latter were surrounded by borders of osified cartilage, and they contained osteoid tissue and large vessels. The calcification of the cartilage took place very irregularly, and in extreme rickets was almost completely absent. The "medullary spaces" also presented an irregular character; they advanced to different heights, and narrowed into the cartilage in all directions. Ossification of cartilage went on here and there between and around the medullary spaces, which low down might be seen lined with lamelle of bone. The medullary spaces often contained great size; in parts, their bony septa might disappear, inasmuch as, at the same time that new bony layers were being deposited, the architecture of the bone became completely altered. With regard to this defective calcification, Kassowitz's view—viz., that both in rickets and in osteomalacia the lifeless parts were new formations laid down in the place of absorbed calcified bone, and were never due to decalcification—was discussed and illustrated. The immature peridental deposits were next referred to. Dr. Bury next related the particulars of a case of infantile osteomalacia, and exhibited some of the bones. These were very soft, and filled with red pulpy material. They presented no epiphyseal enlargements. Lastly, the nature of rickets and its pathological affinities were briefly considered. Dr. Bury regarded more hyperplasia as the main pathological feature, deeming it inexplicable to class it as an inflammatory condition, on the ground of insufficient evidence.

The Anatomy of Hexamobrises.—At a recent meeting of the Pathological Society of London ("British Medical Journal") Mr. Roccobel said that there were two views with regard to the structure of the hexamobrises; according to the one they were varices, according to the other they were vascular growths (angiomata). He had examined about thirty specimens; as a rule a pile consisted of a layer of mucous membrane including some submucous tissue in which lay enlarged veins with thickened walls; in one specimen only did arteries contribute in any sensible degree to the bulk of the pile, and in one case also the pile contained some muscular tissue. The epithelium on a pile ceased, at a certain point, to be columnar, and became squamous; the transition was not gradual, but quite sudden.

Subcutaneous Isolation for Sheep-fox.—A communication on this subject from M. Pech, of Toulouse, has been submitted to the French Academy of Medicine ("Lyonnaise médicale," Nov. 11, 1888). It gives an account of recent experiments with sheep-fox virus which had been reduced in strength by the combined agencies of dilution and the lapse of time. Seventy sheep were inoculated, the dilutions used being the 1-60, the 1-100, and the 1-160. The following facts were established: 1, That the immediate effects of the inoculation were less strongly marked when the virus had been kept for several months than when it was injected in a fresh state; 2, that, for this particular purpose ("clavization"), the hypodermic needle was preferable to the lancet, since, by the employment of the former, a perfect puncture might be obtained—unaccompanied by a general eruption—even from a very small quantity of matter eight or nine montile old, which, if inserted in the ordinary way, would give rise to no symptoms whatever.

Masked Epilepsy.—A treatise on this complaint, by E. Hjertstrøm, is reviewed in the "Nordisk medicinskt Arkiv," vol. xx, No. 8. The author defines masked epilepsy as a form of acute relapsing mania—or of mania becoming chronic through relapses—without convulsive seizures, but to which an epileptic character is imparted by the symptoms which invariably accompany it. His principal object is to offer an ex-
planation of the disease from an anatomical and physiological standpoint. Basing his conclusions upon Nohagel's investigations into the nature of epilepsy in general, and the opinions of Meynert and others concerning masked epilepsy, Hjertström assigns as the cause of the psychical phenomena in the latter, spasm of the nutritive vessels of the cortical layers, produced by an irritation of the vaso-motor center. All the symptoms can be explained by the pathological condition of the cerebral vessels during the paroxysm—but particularly the loss of consciousness, or amnesia, which is more complete in proportion to the severity of the spasm. The alteration of psychical symptoms and convulsions is regarded, in accordance with Nohagel's theory, as due to the co-ordinate and yet independent relation subsisting between the vaso-motor and the convulsive centers, the minimum of irritability at the latter point being considered to exceed the minimum of irritability at the former.

The Relative Excitability of the Superficial and the Deep-seated Portions of the Brain.—The older anatomists held that the interior of the brain responded readily to the action of irritants, but that its surface was insensitive. Later investigations have shown this conclusion to be only partially correct, and that, at least in certain species of animals, portions of the cortical region are more or less sensitive. According to M. Franck and M. Pilé, the superficial cerebral layers are decidedly the most excitable. They found that electrical stimulation of the subcortical portions did not give rise to spasm. M. Canty, however ("Gazette du Comité médical et de chirurgie," Nov. 9, 1883), recently instigated a new series of experiments upon dogs and monkeys, the results of which tend to establish that the application of electricity produces precisely similar effects upon the white substance of the brain and upon its cortex; but that, conformably to the ancient idea, the sensibility of the white substance increases in proportion to its distance from the surface; or, more strictly speaking, in proportion as it approaches the occipital protuberance and the medulla oblongata—those real centers for the reception and diffusion of all cerebral impressions.

Auto-Infection.—It has been shown by Senator, in a paper on this obscure but interesting subject, read before the Berlin Medical Society ("Gaz. hebdo. de méd. et de chir.," Nov. 9, 1883), that the system may become diseased through abnormal decomposition of digestive products within the intestinal tract ("autochthonic" or "autogenetic" infection), and that like processes may also take place in other organs, as, for instance, in the kidneys. Even the blood itself may furnish poisonous alkaloids, of which little is known excepting by their effects. The nervous and the urinary apparatus are chiefly liable to be deranged by these influences. One of the most remarkable phenomena to which they give rise is the condition denominated by Senator dysenteric constipation. He describes as identical in all its features with the "diarrhoea constans" of Kussmuller. He has met with it in two cases of chronic cystitis, with amenorrheal urine (in one of which the patient exhibited an unmistakable odor or trimethylamine), in two cases of cancer of the stomach, and in three cases of pernicious anæmia. In none of these could the presence of acetone be detected in the urine.

Dr. Litten remarked that cases of autochthonic poisoning were much more frequent than was generally supposed. He himself had observed its effects in certain gastro-intestinal disorders—some time ago in a young girl laboring under scarlatina, and more recently in three adults. The patients lay as if dead-drunk; could not be aroused to answer questions, but fell back and went to sleep immediately. The urine in every instance responded to the tests for acetone. As this condition was always preceded by symptoms of dyspepsia, it might be denominated constans dyspepticum. He had no doubt it was due to an actual poisoning by some unknown agent, perhaps an alkaloid, which was generated within the digestive canal in the majority of cases.

The Differential Diagnosis of Tic Douloureux and Dental Neuralgia.—Magitot, of Paris, some time ago expressed the opinion that these two varieties of prosopalgia were clearly distinguishable by their symptoms alone. Tic douloureux he would define as an affection of the cutaneous branches of the trigeminal, occurring in paroxysms of the most violent and spasmodic character which are provoked by the slightest contact or movement; while neuralgia originating in the teeth is always increased or diminished by forces acting upon the oral cavity, such as the pressure of foreign bodies, atmospheric air, heat, cold, certain drugs, etc., none of which exert any influence in the case of tic. This view is controverted by Dr. Th. Walzberg, in the "Centrallblatt für Chirurgie," November 10, 1883. He maintains that there is nothing specially characteristiqué in the symptoms of either complaint, and proposes to divide the facial neuralgias into two classes, viz.: those whose causes can, and those whose causes cannot, be determined—the latter answering to the tic douloureux of Magitot. He adduces in confirmation three cases of prosopalgia successfully treated by himself. Concerning the first two of these he observes that they exhibit almost precisely the same assemblage of symptoms, yet that one of them certainly did not originate in the teeth, although presenting all the features characteristic of dental neuralgia, according to the French author. The third case, the symptoms of which would place it in Magitot's first class (tic douloureux)—and which also strongly resembled an intermittent disease—shows that a neuralgia may arise from the teeth, although entirely uninfluenced by agencies affecting the interior of the mouth. Symptoms in these complaints may facilitate the discovery of their causes, and so guide us to a successful plan of treatment, but only the most accurate objective examination in every case will protect effectively against error. It is better to search in vain for a tooth- root, upon the slightest suspicion, than uselessly to divide a nerve. A remark is appended relating to the mode of performing this operation. When it is designed to follow up to any considerable extent the ramifications of the infraorbital nerve upon the cheek, it is better to make the entering (sincipital) incision at a point somewhat below the orbital wall; otherwise a posset will be formed too small for separate drainage, but large enough to act as a reservoir for the secretions, with the result of setting up a suppuration which will much prolong the process of healing. The latter, under favorable circumstances, should not occupy over five days.

An Electric Lamp for Surgical Purposes.—Mr. E. Crosswell Baber ("British Medical Journal," November 10, 1883) describes a new illuminating apparatus (the photophore électrique frontal) invented by MM. Hidot and Trouvé. It has already been mentioned briefly in this journal. It consists of a small incandescent lamp of eight to ten candle power, inclosed in a metallic cylinder which is closed at one end by a concave glass reflector, and at the other by a bull's-eye lens. The distance of the latter from the glass globe can be regulated at will, or it can be entirely removed from the bottle. The whole apparatus consists of a base, the four sides of which are means of a ball-and-socket joint, to a curved plate fixed to the observer's forehead by means of a head-band, in the usual way. If desired, the lamp can be made into a stationary one by screwing it off the head band and attaching it to a rod which is fixed into the top of a small leather case into which the whole apparatus packs. The lamp is worked by a battery consisting of four to six large cells, each containing one plate of zinc and two of carbon, immersed in a strong solution of sulphuric acid and bichromate of potash. The six cells are arranged in a row, and the plates are suspended by chains to an axle, by the rotation of which they can be raised or lowered, being retained in any position by means of a catch. When not in use, they are, of course, raised quite out of the liquid. According to M. Hidot, the battery lasts without recharging for eight or ten weeks, if used for several patients daily. The case of the battery measures 6¾ x 3½ x 1½ inches, thus taking up very little space in the consulting-room. It has the advantage of giving off no smell; and, being inclosed, merely appears as a stained wooden case of the size described standing on the floor by the side of the patient's chair.

Comparing this light with that of an Argand gas flame, fitted with a bull's-eye condenser, it appears whiter and more powerful. This lamp gives an admirable light for laryngoscopy and posterior rhinoscopy, also for examination of the anterior nares and of the ear. A great advantage which it possesses over light thrown in by means of a reflector attached to the forehead is, that the beam of light of itself follows each movement of the observer's head. It has the further advantages of being ready for use at a moment's notice at any time, and of presenting a very steady, even light. Its chief disadvantage consists in

Dec. 29, 1883]  
MISCELLANY.  
720.
the observer’s eye not being exactly in the axis of light, as in the case of the perforated head mirror. This is only noticeable in examinations of the anterior nares and of the ear, but can, to a great extent, be overcome by a little practice. The lamp will also doubtless be of use for gynecological operations or examinations, as well as for operations on deep-seated parts.

**Compulsory Medical Examinations.**—It is a frequent occurrence, in suits for injuries to the person, to have the plaintiff exhibit in court the limb which has suffered through the negligence of the party from whom damages are claimed, and very often such an exhibit prove a potent argument with the jury for a large verdict. It is a very different matter, however, for a defendant to come before the Court and ask for an order directing the plaintiff to submit to an examination to show whether the injuries are not altogether feigned, or are not the result, to a large extent, of some disease unconnected with the accident. Such a method of procedure, if rigorously carried out, might prevent a jury from rendering a verdict disproportionate to the real injury suffered; but the danger of unpleasant and perhaps inmodest examinations in case of a female plaintiff has recently led a court in this State to decide that it is not proper to issue an order obliging the plaintiff to submit to such an examination. In that case, where a lady sued the Ogdenburgh and Lake Champlain Railroad Co., the defense was that the apparent injury came largely from a disease, which statement might be proved by an examination.

The order was granted in the first instance, but was reversed on appeal, the Court holding as follows: “There may be danger that, in actions of this nature, that plaintiffs will exaggerate the injuries they have received; and that defendants may be at a disadvantage in ascertaining the exact truth. But this evil is far less than the adoption of a system of bodily and perhaps inmodest examinations, which might deter many, especially women, from ever commencing actions, however great the injuries they had sustained.”

**Sulphoindinobenzol as a Test for Bilirubin.**—Professor Ehrlich (“Centralblatt für klinische Medicin,” Nov. 10, 1883) has ascertained that when a solution of bilirubin in chloroform is combined with a proper amount of sulphoindinobenzol containing the litre 1 c.c. of sulpharic acid, 15 c.c.c. of hydrochloric acid, and 0.1 c.c. of nitrate of sodium, and sufficient alcohol is added to make the fluid homogeneous, the color of the latter will change in about one minute to a red, of a darker or lighter shade according to the proportion of bilirubin. If, in the next place, concentrated hydrochloric acid be gradually dropped into the mixture, the color will turn first to violet, then to bluish violet, and finally to a pure, deep, and splendid blue. The liquid now contains a pigment which will impart a variety of tints according to the chemical reaction of the menstruum with which it is united. A strongly acid fluid will be colored a pale blue, a strongly alkaline one greenish blue, while a feebly acid, a feebly alkaline, or a neutral solution will appear violet. In like manner, if a potash-lime be poured carefully into the blue (acid) solution, three colors will be produced—i. e., a hand of greenish-blue below, one of pure blue above, and a narrow ring of red between them. The same pigments were easily obtained from specimens of urine strongly charged with biliary coloring matter, and impart the same characteristic tints to the various reacting fluids. These results prove sulphoindinobenzol to be the special test for bilirubin, since the phenomena described could not be obtained in connection with any other of the biliary coloring matters. Gmelin’s process, on the other hand, constitutes a test for these matters collectively, as it brings out the characteristic colored rings with all of them, though more particularly with bilirubin. It follows that, when we wish to demonstrate the presence or absence of the biliary pigments in general, we should have recourse to Gmelin’s test in the first place, as the most comprehensive, but that Ehrlich’s is preferable when bilirubin alone is sought for. The two processes, however, do not exclude, but supplement each other, and their combined employment may be expected to yield interesting results. In applying his test, the author recommends that the urine be first mixed with an equal volume of dilute acetic acid, and the sulphoindinobenzol then added drop by drop. If the fluid darkens, the further addition of an acid will call forth the violet hue characteristic of bilirubin.

**The Origin of “Spontaneous” Gangrene.**—At the annual meeting of the French Association for the Advancement of Science (“Revue de chirurgie,” Nov., 1883) M. Cerné reported the case of a man sixty years of age, who had several gangrenous sores, with emaciation, polyuria, itching of the skin, etc. His urine was neither saccharine nor albuminous, but contained a large amount of phosphoric acid. He recovered slowly under treatment, and the phosphates at the same time diminished in his urine. This instance of phosphatic diabetes, which perhaps had been preceded by genuine diabetes, showed that the absence of sugar in the urine was not necessarily inconsistent, in such cases, with the existence of constitutional disease; and further observation would doubtless result in demonstrating a close relationship among the various affections of this class. M. Vernet remarked that M. Cerné’s case tended to confirm an opinion which he himself had long entertained, viz.: that all cases of so-called spontaneous gangrene—that is, such as had not evidently originated in severe injuries—were due to an internal cause, sometimes difficult to find, but which was always discoverable by a thorough and persevering examination of the patient. It was especially difficult to detect these organic changes in the urine, be, cause here they were so transient. The sugar appeared and disappeared under various influences, such as change of diet, taking cold, trauma, 

**Army Intelligence.**—**Official List of Changes of Officers serving in the Medical Department of the United States Army from December 8, 1883, to December 22, 1883.—McKee, J. C., Major and Surgeon. Assigned to duty as Medical Director, Department of the Columbia. G. O. 31, Department of the Columbia, December 3, 1883.——** SHELDT, Robert W., Captain and Assistant Surgeon. Now on sick leave, relieved from duty in the Department of the East, and assigned to temporary duty in the office of the Surgeon-General of the Army. S. O. 284, par. 12, A. G. O., December 12, 1883.——** CAMPBELL, John, Lieutenant-Colonel and Surgeon. Having completed the duties pertaining to the office of the Medical Director of the late Department of the South, to proceed from Newport Barracks, Ky., to New York city, and assume the duties of attending surgeon in that city. Par. 12, S. O. 284, A. G. O., December 12, 1883.——** CLEMENTS, BENNET A., Major and Surgeon. Relieved from duty as attending surgeon, New York city, and detailed as member of Army Medical Examining Board, now in session in New York city. Par. 12, S. O. 284, A. G. O., December 12, 1883.——** WILLIAMS, John W., Major and Surgeon. Leave of absence on surgeon’s certificate of disability granted in S. O. 157, November 12, 1883, Department of the Columbia, extended five months on surgeon’s certificate of disability. Par. 5, S. O. 286, A. G. O., December 14, 1883.

**Naval Intelligence.**—**Official List of Changes in the Medical Corps of the Navy during week ending December 22, 1883.—Passed Assistant Surgeon F. C. Dalke, detached from the Coast Survey steamer McArthur, and ordered to the United States steamship Adams at Sitka, Alaska.——** ASSISTANT SURGEON L. W. CURTIS, detached from the Adams and ordered to the Coast Survey steamer McArthur.——** W. Ross, detached from the United States steamer Iroquois and ordered to the United States steamship Onward at Callao, Peru.——** Passed Assistant Surgeon C. T. HIBBETT, detached from the Onward and ordered home.

**Society Meetings for the Coming Week.**—Tuesday, January 1st: New York Neurological Society; Elnira (N. Y.) Academy of Medicine; Buffalo Medical Association; Ogdenburgh Medical Association; Croton Medical and Surgical Union (Katonah, N. Y.); Medical Societies of the Counties of Broome and Niagara, N. Y., and Hudson and Union, N. J. Wednesday, January 2d: New York Medico-Legal Society; Medical Society of the County of Richmond, N. Y. Thursday, January 3d: New York Academy of Medicine (annual election); Society of Physicians of the Village of Canandaigua, N. Y.
INDEX TO VOLUME XXXVIII.
